CancelCurrentWork

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Set function cancellation flag. Function is thread-safe.

Syntax

```
void avl::CancelCurrentWork()
```

CloseGPUProcessing

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Disables GPU processing.

Syntax

```
void avl::CloseGPUProcessing()
```

DischargeAVLImageMemoryPools

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Clears images in the AVL memory pool.

Syntax

```
void avl::DischargeAVLImageMemoryPools()
```

EnableAvlDiagnosticOutputs

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables computation of diagnostics outputs.

Syntax

```
void avl::EnableAvlDiagnosticOutputs
(
 bool enable
)
```

Parameters

Name	Type	Default	Description
enable	bool		

EnableAVX2Acceleration

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables AVX2 acceleration.

Syntax

```
void avl::EnableAVX2Acceleration
(
 bool enable
)
```

Parameters

Name	Type	Default	Description
enable	bool		

Also in AVL Lite

EnableGPUProcessing

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables GPU processing.

Syntax

```
void avl::EnableGPUProcessing
(
 bool inEnabled
)
```

Parameters

Name	Type	Default	Description
inEnabled	bool		

Also in AVL Lite

EnableNEONAcceleration

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables NEON acceleration. Only on ARM CPUs.

Syntax

```
void avl::EnableNEONAcceleration
(
 bool enable
)
```

Parameters

Name	Type	Default	Description
enable	bool		

EnableSSEAcceleration

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables SSE acceleration.

Syntax

```
void avl::EnableSSEAcceleration
(
 bool enable
)
```

Parameters

Name	Type	Default	Description
enable	bool		

GetAvlDiagnosticOutputsEnabled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns AVL diagnostic state.

Syntax

```
bool avl::GetAvlDiagnosticOutputsEnabled()
```

GetAVX2AccelerationEnabled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the state of the AVX2 acceleration.

Syntax

```
bool avl::GetAVX2AccelerationEnabled()
```

GetGPUProcessingDiagInfo

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns GPU diagnostic information.

Syntax

```
bool avl::GetGPUProcessingDiagInfo
(
 atl::String& outDiagInfo
)
```

Parameters

Name	Type	Default	Description
outDiagInfo	String&		

GetNEONAccelerationEnabled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the state of the NEON acceleration.

Syntax

```
bool avl::GetNEONAccelerationEnabled()
```

GetParallelComputingThreadsCount

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns maximal number of threads to be used for computing.

Syntax

```
int avl::GetParallelComputingThreadsCount()
```

GetSSEAccelerationEnabled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns returns state of SSE acceleration.

Syntax

```
bool avl::GetSSEAccelerationEnabled()
```

InitGPUProcessing

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Initializes GPU processing with a selected device.

Syntax

```
void avl::InitGPUProcessing
(
 atl::String& platformName = "",
 atl::String& deviceName = ""
)
```

Parameters

Name	Type	Default	Description
platformName	String&	""	
deviceName	String&	""	

IsCurrentWorkCancelled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns true if function cancellation was requested.

Syntax

```
bool avl::IsCurrentWorkCancelled()
```

ResetIsCurrentWorkCancelled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reset function cancellation flag.

Syntax

```
void avl::ResetIsCurrentWorkCancelled()
```

SetParallelComputing

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Controls the state and number of available threads.

Syntax

```
void avl::SetParallelComputing
(
 bool enabled,
 int num_threads
)
```

Parameters

Name	Type	Default	Description
enabled	bool		
num_threads	int		Numbers of thread available for computation.

ThrowIfCurrentWorkCancelled

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Function throw CancellationException when cancellation flag is set.

Syntax

```
void avl::ThrowIfCurrentWorkCancelled()
```

2. Debug Preview

Table of content:

- ClearViewPrimitive
- CloseAll
- CloseView
- CreateView
- CreateView3D
- SetView3DPrimitive
- SetViewImage
- SetViewPrimitive
- WaitForAllViewsClose
- WaitForViewClose

ClearViewPrimitive

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Clears a primitive slot in the floating window preview.

Syntax

```
void avl::DebugPreview::ClearViewPrimitive
(
 avl::DebugPreview::ViewHandle view,
 int primitiveIndex
)
```

Parameters

Name	Type	Default	Description
view	DebugPreview::ViewHandle		Handle of a preview to alter.
primitiveIndex	int		Slot index to clear.

Description

This function removes a primitive from the debug preview, previously set by the SetViewPrimitive or SetView3DPrimitive functions.

This function will not fail if the primitive with the specified index was not set or was already removed, or when the user already manually closed the preview window.

See Also

- SetViewPrimitive – Sets a 2D primitive into an image debug preview window.
- SetView3DPrimitive – Sets a 3D primitive into a debug preview window.

CloseAll

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Closes all floating preview windows and cleanups the preview subsystem.

Syntax

```
void avl::DebugPreview::CloseAll()
```

Description

This function will close all preview windows, terminate background message pump thread and free debug preview subsystem resources.

After call to this function all view handles will become invalid.

See Also

- WaitForAllViewsClose – Waits for all floating preview windows to be closed by the user.
- CloseView – Closes a floating preview window.

CloseView

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Closes a floating preview window.

Syntax

```
void avl::DebugPreview::CloseView
(
 avl::DebugPreview::ViewHandle view
)
```

Parameters

Name	Type	Default	Description
view	DebugPreview::ViewHandle		Handle of a window to close.

Description

This function will close a preview window opened by CreateView and CreateView3D functions, and release the resources associated with the handle.

After the call to this function the view handle will become invalid.

See Also

- CreateView - Creates a new floating window for a 2D image based data preview.
- CreateView3D - Creates a new floating window for a 3D data preview.
- CloseAll - Closes all floating preview windows and cleanups the preview subsystem.

CreateView

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Creates a new floating window for a 2D image based data preview.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
avl::DebugPreview::ViewHandle avl::DebugPreview::CreateView
(
 const atl::String& name,
 int width = -1,
 int height = -1,
 int posX = -1,
 int posY = -1
)
```

Parameters

Name	Type	Default	Description
name	const String&		Window title.
width	int	-1	Width of the window preview area in pixels.
height	int	-1	Height of the window preview area in pixels.
posX	int	-1	X coordinate of the initial window position.
posY	int	-1	Y coordinate of the initial window position.

Description

The debug preview system helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

This function initializes the preview subsystem and opens a new floating preview window for displaying 2D images and primitives. It is possible to open up to 32 preview windows at once (have up to 32 active preview handles). The user can interact with the preview by moving or resizing the window, zooming and moving the preview content (with mouse and the mouse scroll-wheel) or setting the preview into various modes through the context menu (by right clicking the preview content).

The **name** function argument specifies the caption of the new window.

The **width** and **height** arguments specify the size of the preview content area of the window in pixels. The arguments are optional and can be omitted to use the default window size (the user can resize the window manually).

The **posX** and **posY** arguments specify the initial position of the upper left corner of the window in desktop coordinates. The arguments are optional and can be left on its default values (-1) to automatically arrange the preview window initial layout starting at the top left corner of the desktop.

A preview window will be closed as a result of the following actions:

- the user manually closes the window (view handle remains valid),
- CloseView is called on the view handle,
- CloseAll is called.

This function creates a background thread with a message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till the application closes (even when there are no more windows active). To explicitly close the debug preview subsystem and free its resources call the CloseAll function.

Return value

After successful execution this function returns a handle of the preview (of type **avl::DebugPreview::ViewHandle**). This handle can be used with SetViewImage and SetViewPrimitive functions to set data into the preview, and with WaitForViewClose to wait for the user to close the window (to help with step-by-step debugging).

This handle needs to be explicitly released with CloseView or WaitForViewClose functions to release its resources (even when the user closes the window manually).

See Also

- CloseView - Closes a floating preview window.

CreateView3D

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Creates a new floating window for a 3D data preview.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
avl::DebugPreview::ViewHandle avl::DebugPreview::CreateView3D
(
 const atl::String& name,
 int width = -1,
 int height = -1,
 int posX = -1,
 int posY = -1,
 View3DWorldOrientation::Type worldOrientation = View3DWorldOrientation::RightHandZUp,
 View3DColoring::Type coloring = View3DColoring::ZScaleColoring,
 bool highQuality = true
)
```

Parameters

Name	Type	Default	Description
name	const String&		Window title.
width	int	-1	Width of the window preview area in pixels.
height	int	-1	Height of the window preview area in pixels.
posX	int	-1	X coordinate of the initial window position.
posY	int	-1	Y coordinate of the initial window position.
worldOrientation	View3DWorldOrientation::Type	RightHandZUp	Orientation of the 3D preview space.
coloring	View3DColoring::Type	ZScaleColoring	Mode of the coloring of the point cloud points in the preview.
highQuality	bool	true	Enables or disables high quality drawing in the preview.

Description

The debug preview system helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

This function initializes the preview subsystem and opens a new floating preview window for displaying 3D point clouds, surfaces and primitives. It is possible to open up to 32 preview windows at once (have up to 32 active preview handles). The user can interact with the preview by moving or resizing the window, zooming and rotating the preview content (with mouse and the mouse scroll-wheel) or setting the preview into various modes through the context menu (by right clicking the preview content).

The **name** function argument specifies the caption of the new window.

The **width** and **height** arguments specify the size of the preview content area of the window in pixels. The arguments are optional and can be omitted to use the default window size (the user can resize the window manually).

The **posX** and **posY** arguments specify the initial position of the upper left corner of the window in desktop coordinates. The arguments are optional and can be left on its default values (-1) to automatically arrange the preview window initial layout starting at the top left corner of the desktop.

The **worldOrientation** and **coloring** arguments specify the initial configuration of the 3D preview space. The arguments can be omitted (by default the preview is configured for right-hand coordinate system with z axis up, and for point cloud scale coloring along the z axis). The user can change this configuration manually through the context menu.

Setting the **highQuality** argument to true activates the anti-aliasing in the preview renderer (improves the view quality but requires more video resources and slows down the rendering).

A preview window will be closed as a result of the following actions:

- the user manually closes the window (view handle remains valid),
- CloseView is called on the view handle,
- CloseAll is called.

This function creates a background thread with a message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till the application closes (even when there are no more windows active). To explicitly close the debug preview subsystem and free its resources call the CloseAll function.

Return value

After successful execution this function returns a handle of the preview (of type **avl::DebugPreview::ViewHandle**). This handle can be used with the SetView3DPrimitive functions to set data into the preview, and with WaitForViewClose to wait for the user to close the window (to help with step-by-step debugging).

This handle needs to be explicitly released with CloseView or WaitForViewClose functions to release its resources (even when the user closes the window manually).

See Also

- SetView3DPrimitive – Sets a 3D primitive into a debug preview window.
- CloseView – Closes a floating preview window.

SetView3DPrimitive

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Sets a 3D primitive into a debug preview window.

Description

This function adds/sets a point cloud, surface or 3D primitive to the preview window. Up to 100 primitives distinguished by a slot index can be added to a single preview window.

The following function overloads for various primitive types are available:

```
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Point3DGrid& grid, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Point3DGrid>& gridArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Surface& surface, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Surface>& surfaceArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Plane3D& plane, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Point3D& point, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Point3D>& pointArray, Color color
= AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Circle3D& circle, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Circle3D>& circleArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Sphere3D& sphere, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Sphere3D>& sphereArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Segment3D& segment, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Segment3D>& segmentArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Box3D& box, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Box3D>& boxArray, Color color =
AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Line3D& line, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Line3D>& lineArray, Color color =
AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Path& path, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Path>& pathArray, Color color =
AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Segment2D& segment, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Segment2D>& segmentArray, Color
color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const avl::Region& region, Color color = AutoColor)
bool SetView3DPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Region>& regionArray, Color color
= AutoColor)
```

The **view** argument must provide a handle to the preview created with the CreateView3D function.

The **primitiveIndex** arguments specifies the slot index to set the primitive into (in the range 0...99). Setting the primitive into a slot for the first time initializes the given primitive. Setting the primitive again into the same slot overrides the previous primitive data and type. The slot indexes does not have to be used in consecutive order.

The **color** argument determines the color the primitive is displayed as a 32bit ARGB value (e.g. 0xFFFF0000 for red, or 0xFF0000FF for blue). This parameter is optional and can be omitted or set to AutoColor constant to automatically associate the primitive color based on its index.

Return value

The function returns true when the specified preview window is still active and the new image is displayed in the preview. The function will return false when the preview window associated with the handle has been manually closed by the user and the window is not active anymore.

See Also

- CreateView3D – Creates a new floating window for a 3D data preview.
- ClearViewPrimitive – Clears a primitive slot in the floating window preview.

SetViewImage

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Sets an image to be previewed in the debug preview window.

Syntax

```
bool avl::DebugPreview::SetViewImage
(
 avl::DebugPreview::ViewHandle view,
 const avl::Image& image
)
```

Parameters

Name	Type	Default	Description
view	DebugPreview::ViewHandle		Handle of a preview to set the image to.
image	const Image&		Image data to be previewed.

Description

This function sets the image data to the image preview window. Only one image can be set to a single preview window, calling this function multiple times for a single preview (e.g. over multiple program iterations) will override the previously set image data. When a new image with the same dimensions is set the zoom state of the preview is not changed, when the image size is changed the preview zoom state might be adjusted to accommodate the change.

The **view** argument must provide a handle to the preview created with the CreateView function.

Return value

The function returns true when the specified preview window is still active and the new image is displayed in the preview. The function will return false when the preview window associated with the handle has been manually closed by the user and the window is not active anymore.

See Also

- CreateView – Creates a new floating window for a 2D image based data preview.
- SetViewPrimitive – Sets a 2D primitive into an image debug preview window.

SetViewPrimitive

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Sets a 2D primitive into an image debug preview window.

Description

This function adds/sets a 2D primitive to the image preview window to be displayed on top of the image. Up to 100 primitives distinguished by a slot index can be added to a single preview window.

In order to see a primitive in the view an image first needs to be set using the SetViewImage function.

The following function overloads for various primitive types are available:

```
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Box& box, Color color = AutoColor, float
lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Box>& boxArray, Color color =
AutoColor, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Circle2D& circle, Color color = AutoColor,
float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Circle2D>& circleArray, Color color
= AutoColor, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Arc2D& arc, Color color = AutoColor, float
lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Arc2D>& arcArray, Color color =
AutoColor, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Rectangle2D& rect, Color color = AutoColor,
float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Rectangle2D>& rectArray, Color
color = AutoColor, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Segment2D& segment, Color color = AutoColor,
bool showArrow = true, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Segment2D>& segmentArray, Color
color = AutoColor, bool showArrow = true, float lineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Point2D& point, Color color = AutoColor)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const atl::Array<avl::Point2D>& pointArray, Color color =
AutoColor)

color = AutoColor, float LineWidth = DefaultLineWidth)
bool SetViewPrimitive(ViewHandle view, int primitiveIndex, const avl::Rectangle2D& rect, const atl::String& label,
Color color = AutoColor, float LineWidth = DefaultLineWidth)
```

The **view** argument must provide a handle to the preview created with the CreateView function.

The **primitiveIndex** arguments specifies the slot index to set the primitive into (in the range 0...99). Setting the primitive into a slot for the first time initializes the given primitive. Setting the primitive again into the same slot overrides the previous primitive data and type. The slot indexes does not have to be used in consecutive order. Slot indexes determine the z-order of primitives in the preview.

The **color** argument determines the color the primitive is displayed as a 32bit ARGB value (e.g. 0xFFFF0000 for red, or 0xFF0000FF for blue). This parameter is optional and can be omitted or set to AutoColor constant to automatically associate the primitive color based on its index.

Return value

The function returns true when the specified preview window is still active and the new image is displayed in the preview. The function will return false when the preview window associated with the handle has been manually closed by the user and the window is not active anymore.

See Also

- CreateView – Creates a new floating window for a 2D image based data preview.
- SetViewImage – Sets an image to be previewed in the debug preview window.
- ClearViewPrimitive – Clears a primitive slot in the floating window preview.

WaitForAllViewsClose

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Waits for all floating preview windows to be closed by the user.

Syntax

```
void avl::DebugPreview::WaitForAllViewsClose()
```

Description

This function will block the execution until the user manually closes all active preview windows, or until the debug preview subsystem is terminated by other threads. During the waiting period all preview windows remain responsive.

This function will not invalidate any view handles. All allocated view handles still have to be close with CloseView or CloseAll functions.

See Also

- CloseAll – Closes all floating preview windows and cleanups the preview subsystem.

WaitForViewClose

Header: AVL.h
Namespace: avl::DebugPreview
Module: FoundationLite

Waits for a specified floating preview window to be closed by the user.

Syntax

```
void avl::DebugPreview::WaitForViewClose
(
 avl::DebugPreview::ViewHandle view
)
```

Parameters

Name	Type	Default	Description
view	DebugPreview::ViewHandle		Handle of a window to wait for.

Description

This function will block the execution until the user manually closes the preview window associated with the specified handle, or until the debug preview subsystem is terminated by other threads. During the waiting period all preview windows remain responsive.

This function will also close the view handle releasing its resources. It is not necessary to additionally call the CloseView function on the same handle.

After the call to this function the view handle will become invalid.

See Also

- CloseAll – Closes all floating preview windows and cleanups the preview subsystem.

3. Legacy Preview

DebugPreviewCloseAllWindows

Header: AVL.h
Namespace: avl
Module: FoundationLite

Closes all active debug preview windows and terminates the preview window subsystem.

Syntax

```
void avl::DebugPreviewCloseAllWindows()
```

Description

This function will close all active preview windows, terminate background message pump thread and free debug preview subsystem resources.

After call to this function all preview window state objects become invalid.

See Also

- DebugPreviewWaitForWindowsClose – Waits until the user closes all active debug windows.

Also in AVL Lite

DebugPreviewCloseWindow

Header: AVL.h
Namespace: avl
Module: FoundationLite

Closes a debug preview window.

Syntax

```
void avl::DebugPreviewCloseWindow
(
 DebugPreviewWindowState& ioWindow
)
```

Parameters

	Name	Type	Default	Description
	ioWindow	DebugPreviewWindowState&		State object of window to be closed.

Description

This function will close the window bound to the specified state object (opened by DebugPreviewShowImage or DebugPreviewShowRegion) and free the resource occupied by the state object.

After call to this function, the state object will become invalid. Function invoked on an invalid state object ends with no results.

DebugPreviewShowImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shows an image in a separated window. When called for the first time, it creates a new window with size fitted to the image.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
bool avl::DebugPreviewShowImage
(
 DebugPreviewWindowState& ioState,
 const Image& inImage,
 const wchar_t* inWindowName,
 int inPosX,
 int inPosY
)
```

Parameters

	Name	Type	Default	Description
	ioState	DebugPreviewWindowState&		Object used to maintain state of the function.
	inImage	const Image&		Image to preview.
	inWindowName	const wchar_t*	"Image Preview"	Name of newly opened window.
	inPosX	int	Windows default	X coordinate of initial windows position.
	inPosY	int	Windows default	Y coordinate of initial windows position.

Description

This function helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

A preview window is bound to the state object specified in the first argument of the function. On the first call on specified state object instance, this function will create and show a new floating window with size fitted to the specified image. Every subsequent call on the same state object instance will only update the image in preview.

A preview window will be closed as a result of the following actions:

- the user closes the window using its tool box (state object remains valid),
- the state object of the window is destructed,
- DebugPreviewCloseWindow is called on the window state object,
- DebugPreviewCloseAllWindows is called.

This function creates a background thread with message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till application close (even when no more windows are active). To explicitly close the debug preview subsystem and free its resources call DebugPreviewCloseAllWindows function.

Leaving the start position set to its default value (-1x-1) will automatically arrange windows, starting from top left corner of the screen.

Return value

This function returns true after successful creation or update of an active window. After such window is closed by the user, subsequent calls to this function will return false.

See Also

- DebugPreviewShowRegion – Shows a region in a separated window. When called for the first time, creates a new window with size fitted to the region.
- DebugPreviewCloseWindow – Closes a debug preview window.

DebugPreviewShowNewImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a new separated window and shows an image in it.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
void avl::DebugPreviewShowNewImage
(
 const Image& inImage,
 const wchar_t* inWindowName,
 int inPosX,
 int inPosY
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	const Image&		Image to preview.
➡	inWindowName	const wchar_t*	"Image Preview"	Name of newly opened window.
➡	inPosX	int	Windows default	X coordinate of initial windows position.
➡	inPosY	int	Windows default	Y coordinate of initial windows position.

Description

This function helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

Calling this function will create a new preview window with size fitted to the specified image. Such window is shown with the specified image but without returning any reference or handle. The new windows will remain active until it is closed by the user or by DebugPreviewCloseAllWindows function call. An application can call this function multiple times to open multiple windows as long as the limit of 32 simultaneously active windows is not exceeded.

This function creates a background thread with message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till application close (even when no more windows are active). To explicitly close the debug preview subsystem and free its resources call DebugPreviewCloseAllWindows function.

Leaving the start position set to its default value (-1x-1) will automatically arrange windows, starting from top left corner of the screen.

See Also

- DebugPreviewShowNewRegion – Creates a new separated window and shows a region in it.
- DebugPreviewWaitForWindowsClose – Waits until the user closes all active debug windows.
- DebugPreviewCloseAllWindows – Closes all active debug preview windows and terminates the preview window subsystem.

DebugPreviewShowNewRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a new separated window and shows a region in it.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
void avl::DebugPreviewShowNewRegion
(
 const Region& inRegion,
 const wchar_t* inWindowName,
 int inPosX,
 int inPosY
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Region to preview.
➡	inWindowName	const wchar_t*	"Region Preview"	Name of newly opened window.
➡	inPosX	int	Windows default	X coordinate of initial windows position.
➡	inPosY	int	Windows default	Y coordinate of initial windows position.

Description

This function helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

Calling this function will create a new preview window with size fitted to the specified region. Such window is shown with the specified region but without returning any reference or handle. The new windows will remain active until it is closed by the user or by DebugPreviewCloseAllWindows function call. An application can call this function multiple times to open multiple windows as long as the limit of 32 simultaneously active windows is not exceeded.

This function creates a background thread with message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till application close (even when no more windows are active). To explicitly close the debug preview subsystem and free its resources call DebugPreviewCloseAllWindows function.

Leaving the start position set to its default value (-1x-1) will automatically arrange windows, starting from top left corner of the screen.

See Also

- DebugPreviewShowNewImage – Creates a new separated window and shows an image in it.
- DebugPreviewWaitForWindowsClose – Waits until the user closes all active debug windows.
- DebugPreviewCloseAllWindows – Closes all active debug preview windows and terminates the preview window subsystem.

DebugPreviewShowRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shows a region in a separated window. When called for the first time, creates a new window with size fitted to the region.

Applications: This function is for development purpose only and requires Library Professional license.

Syntax

```
bool avl::DebugPreviewShowRegion
(
 DebugPreviewWindowState& ioState,
 const Region& inRegion,
 const wchar_t* inWindowName,
 int inPosX,
 int inPosY
)
```

Parameters

	Name	Type	Default	Description
	ioState	DebugPreviewWindowState&		Object used to maintain state of the function.
	inRegion	const Region&		Region to preview.
	inWindowName	const wchar_t*	"Region Preview"	Name of newly opened window.
	inPosX	int	Windows default	X coordinate of initial windows position.
	inPosY	int	Windows default	Y coordinate of initial windows position.

Description

This function helps in debugging of Aurora Vision Library based applications by providing a quick but primitive way to preview internal application image-oriented data in floating windows.

A preview window is bound to the state object specified in the first argument of the function. On the first call on specified state object instance, this function will create and show a new floating window with size fitted to the specified region. Every subsequent call on the same state object instance will only update the region in preview.

A preview window will be closed as a result of the following actions:

- the user closes the window using its tool box (state object remains valid),
- the state object of the window is destructed,
- DebugPreviewCloseWindow is called on the window state object,
- DebugPreviewCloseAllWindows is called.

This function creates a background thread with message pump (single thread shared by all windows in the debug preview subsystem) that will stay active till application close (even when no more windows are active). To explicitly close the debug preview subsystem and free its resources call DebugPreviewCloseAllWindows function.

Leaving the start position set to its default value (-1x-1) will automatically arrange windows, starting from top left corner of the screen.

Return value

This function returns true after successful creation or update of an active window. After such window is closed by the user, subsequent calls to this function will return false.

See Also

- DebugPreviewShowImage – Shows an image in a separated window. When called for the first time, it creates a new window with size fitted to the image.

4. Json

Table of content:

DeserializeFromJson

Header: STD.h
Namespace: avl
Module: FoundationLite

Deserializes structure from JsonData object.

Syntax

```
void avl::DeserializeFromJson
(
 const avl::JsonData& inJson,
 bool inIgnoreCasing,
 bool inValidate,
 Type& outObject
)
```

Parameters

	Name	Type	Default	Description
→	inJson	const JsonData&		JsonData to be deserialized.
→	inIgnoreCasing	bool	false	Whether to ignore casing when searching for the key.
→	inValidate	bool	true	Whether to validate if the key exists and throw an error, or to fill with the default value.
←	outObject	Type&		Deserialized structure from JsonData.

Remarks

Working with JSON data

Introduction

This filter is intended to interact with data saved in JSON format.

A JSON document is composed of objects and arrays nested within each other. Each document has the main object where all other data is stored. Data in objects is stored in a key-value fashion, while data in arrays is a sequence of values. Objects are marked with braces and arrays are marked with square brackets.

The JSON filters use a custom data type that represents a single element of a JSON document. An element may represent both JSON data structures - arrays and objects, but also values stored inside them - numerics, strings or booleans.

Loading a JSON document from a file

To load a JSON document from a file, the Json_LoadFile filter is used.

During loading of a JSON document it is possible to set various format parameters and parsing options. These can also be set at a later time for each JSON data structure individually using Json_SetFormatParameters and Json_SetParseOptions filters. When nesting JSON data structures, format parameters and parsing options of the higher data structure are used for the resulting structure.

Format parameters

The JsonFormatParameters allow for a more readable preview of JSON data in Aurora Vision Studio and specify the indentation of the JSON document when saving it to a file. It is recommended to disable the indentation if the preview is not used, as it introduces a small performance cost.

Accessing JSON data

After loading a JSON file all properties of arrays and objects can be accessed with Json_Access_Array and Json_Access_Object filters.

Filters from groups Json_GetValue_FromArray_* and Json_GetValue_FromObject_* can be used to access directly a value from an array or an object using its index or key. These filters are available for Bool, Int64, Uint64, Double, String, Array and Object types.

Many of these filters have OrNil variants that return **Nil** instead of throwing an error when a key doesn't exist or when the JSON value is null. The OrNil variants include an **inValidate** parameter: when set to **false** (default), the filter returns Nil for missing keys or type mismatches; when set to **true**, the filter throws an error for missing keys but still returns Nil for null JSON values.

Values of other types, such as Bool, Double, Int64, Uint64 and String can be extracted from JSON data structures of the corresponding types using the Json_GetValue_FromJsonData_* filters.

To check if a key exists in a JSON object or array, use the Json_KeyExistsIn_* filters. To get the data type of a value in JSON data, use the Json_GetElementType_* filters.

> **Warning:** Numeric Json_GetValue filters perform automatic type conversion between int64, uint64, and double. Conversions may silently truncate decimal values (double -> integer) or lose precision (large integer -> double) without throwing exceptions, provided the source is a valid JSON number.

Creating a JSON document

The process of creating JSON documents is organized in a bottom-up approach. At the beginning, the lowest structures of the document must be created. Then, such structures can be added to a structure at a higher level in the document and that structure can be added to some yet higher structure and so on. The structure at the highest level in hierarchy must be an object.

To create an empty JSON structure Json_CreateEmpty_Array and Json_CreateEmpty_Object filters should be used.

Created JSON structures should be nested in other structures using the filters from groups Json_InsertValue_IntoArray_* and Json_SetValue_InObject_* . New structures will be added at the specified index or key. These filters are available for Bool, Int64, Uint64, Double, String, Array, Object and Null types.

The OrNil variants of these filters allow inserting **null** values into JSON by passing Nil as the value parameter. For example, Json_SetValue_InObject_Bool_OrNil can insert either a boolean value or a JSON null.

To remove a nested structure from an array or an object, the filters from group Json_RemoveValue_* can be used.

Saving a JSON document to a file

To save a JSON document to a file, the Json_SaveFile filter is used.

Other

JSON data structures can be converted to and built from strings using JsonDataToString and StringToJsonData filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

SerializeToJson

Header: STD.h
Namespace: avl
Module: FoundationLite

Serializes structure to JsonData object.

Syntax

```
void avl::SerializeToJson
(
 const Type& inObject,
 const avl::JsonFormatParameters& inFormatParameters,
 const avl::JsonParseOptions& inParseOptions,
 avl::JsonData& outJson
)
```

Parameters

	Name	Type	Default	Description
→	inObject	const Type&		Object to be saved.
→	inFormatParameters	const JsonFormatParameters&		Format parameters.
→	inParseOptions	const JsonParseOptions&		Parse options.
←	outJson	JsonData&		Serialized structure to JsonData.

Remarks

Loading a JSON document from a file

To load a JSON document from a file, the Json_LoadFile filter is used.

During loading of a JSON document it is possible to set various format parameters and parsing options. These can also be set at a later time for each JSON data structure individually using Json_SetFormatParameters and Json_SetParseOptions filters. When nesting JSON data structures, format parameters and parsing options of the higher data structure are used for the resulting structure.

Format parameters

The JsonFormatParameters allow for a more readable preview of JSON data in Aurora Vision Studio and specify the indentation of the JSON document when saving it to a file. It is recommended to disable the indentation if the preview is not used, as it introduces a small performance cost.

Accessing JSON data

After loading a JSON file all properties of arrays and objects can be accessed with Json_Access_Array and Json_Access_Object filters.

Filters from groups Json_GetValue_FromArray_* and Json_GetValue_FromObject_* can be used to access directly a value from an array or an object using its index or key. These filters are available for Bool, Int64, Uint64, Double, String, Array and Object types.

Many of these filters have OrNil variants that return **Nil** instead of throwing an error when a key doesn't exist or when the JSON value is null. The OrNil variants include an **inValidate** parameter: when set to **false** (default), the filter returns Nil for missing keys or type mismatches; when set to **true**, the filter throws an error for missing keys but still returns Nil for null JSON values.

Values of other types, such as Bool, Double, Int64, Uint64 and String can be extracted from JSON data structures of the corresponding types using the Json_GetValue_FromJsonData_* filters.

To check if a key exists in a JSON object or array, use the Json_KeyExistsIn_* filters. To get the data type of a value in JSON data, use the Json_GetElementType_* filters.

> **Warning:** Numeric Json_GetValue filters perform automatic type conversion between int64, uint64, and double. Conversions may silently truncate decimal values (double -> integer) or lose precision (large integer -> double) without throwing exceptions, provided the source is a valid JSON number.

Creating a JSON document

The process of creating JSON documents is organized in a bottom-up approach. At the beginning, the lowest structures of the document must be created. Then, such structures can be added to a structure at a higher level in the document and that structure can be added to some yet higher structure and so on. The structure at the highest level in hierarchy must be an object.

To create an empty JSON structure Json_CreateEmpty_Array and Json_CreateEmpty_Object filters should be used.

Created JSON structures should be nested in other structures using the filters from groups Json_InsertValue_IntoArray_* and Json_SetValue_InObject_* . New structures will be added at the specified index or key. These filters are available for Bool, Int64, Uint64, Double, String, Array, Object and Null types.

The OrNil variants of these filters allow inserting **null** values into JSON by passing Nil as the value parameter. For example, Json_SetValue_InObject_Bool_OrNil can insert either a boolean value or a JSON null.

To remove a nested structure from an array or an object, the filters from group Json_RemoveValue_* can be used.

Saving a JSON document to a file

To save a JSON document to a file, the Json_SaveFile filter is used.

Other

JSON data structures can be converted to and built from strings using JsonDataToString and StringToJsonData filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

EnumerateObjects

Header: STD.h
Namespace: avl
Module: FoundationLite

Enumerates the avdata files present in a disk directory and sorts them according to the specified order and loads an object from a file.

Syntax

```
bool avl::EnumerateObjects
(
 EnumerateFilesState& ioState,
 const atl::Directory& inDirectory,
 avl::FileSortingOrder::Type inSortingOrder,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 avl::StreamMode::Type inStreamMode,
 atl::File& outFilePath,
 atl::String& outFileName,
 Type& outObject,
 atl::Optional<bool> outIsFirst = atl::NIL,
 atl::Optional<bool> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	EnumerateFilesState&		Object used to maintain state of the function.
→	inDirectory	const Directory&		Input directory
→	inSortingOrder	FileSortingOrder::Type		Sorting order
→	inRepeat	bool		Determines whether to repeat reading directory after reading all files
→	inProcessSubdirectories	bool		Flag indicating whether to enumerate files from the subdirectories or not
→	inInvert	bool		Flag indicating whether to enumerate files backwards or not
→	inStreamMode	StreamMode::Type		Binary or text format of the files.
←	outFilePath	File&		Output file path
←	outFileName	String&		Output file name
←	outObject	Type&		
←	outIsFirst	Optional<bool>	NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool>	NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Remarks

Linux

Sorting output by file creation date when running AVL on Linux is not possible due to file system restrictions. When requested to do so EnumerateFiles will throw an exception.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported stream mode in EnumerateObjects function.

See Also

- LoadObject – Loads an AVL object from a file.

EnumerateFiles

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Enumerates the files present in a disk directory.

Syntax

```
bool avl::EnumerateFiles
(
 EnumerateFilesState& ioState,
 const atl::Directory& inDirectory,
 const atl::String& inExtensions,
 avl::FileSortingOrder::Type inSortingOrder,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 atl::File& outFilePath,
 atl::String& outFileName,
 atl::Optional<bool> outIsFirst = atl::NIL,
 atl::Optional<bool> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
	ioState	EnumerateFilesState&		Object used to maintain state of the function.
	inDirectory	const Directory&		Input directory
	inExtensions	const String&		Allowed extensions separated by semicolon
	inSortingOrder	FileSortingOrder::Type		Sorting order
	inRepeat	bool		Determines whether to repeat reading directory after reading all files
	inProcessSubdirectories	bool		Flag indicating whether to enumerate files from the subdirectories or not
	inInvert	bool		Flag indicating whether to enumerate files backwards or not
	outFilePath	File&		Output file path
	outFileName	String&		Output file name
	outIsFirst	Optional<bool>	NIL	Flag indicating the first iteration
	outIsLast	Optional<bool>	NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Remarks

Linux

Sorting output by file creation date when running AVL on Linux is not possible due to file system restrictions. When requested to do so EnumerateFiles will throw an exception.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot sort by file creation date on Linux.
DomainError	Directory doesn't exist: Directory path
DomainError	Empty string is not a valid directory path.

EnumerateFiles_Random

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Enumerates the files present in a disk directory sorted randomly.

Syntax

```
bool avl::EnumerateFiles_Random
(
 EnumerateFilesState& ioState,
 const atl::Directory& inDirectory,
 const atl::String& inExtensions,
 atl::Optional<int> inSeed,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 atl::File& outFilePath,
 atl::String& outFileName,
 atl::Optional<bool> outIsFirst = atl::NIL,
 atl::Optional<bool> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	EnumerateFilesState&		Object used to maintain state of the function.
→	inDirectory	const Directory&		Input directory
→	inExtensions	const String&		Allowed extensions separated by semicolon
→	inSeed	Optional<int>		Random seed used to determine random sorting order
→	inRepeat	bool		Determines whether to repeat reading directory after reading all files
→	inProcessSubdirectories	bool		Flag indicating whether to enumerate files from the subdirectories or not
→	inInvert	bool		Flag indicating whether to enumerate files backwards or not
←	outFilePath	File&		Output file path
←	outFileName	String&		Output file name
←	outIsFirst	Optional<bool>	NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool>	NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot sort by file creation date on Linux.
DomainError	Directory doesn't exist: Directory path
DomainError	Empty string is not a valid directory path.

CheckDiskSpace

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Determines the information about the filesystem on which the pathname inPath is located.

Syntax

```
void avl::CheckDiskSpace
(
 const atl::Directory& inPath,
 atl::int64& outCapacity,
 atl::int64& outFree,
 atl::int64& outAvailable
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Directory&	\".\"	Input path
←	outCapacity	int64&		Total size of the filesystem, in bytes
←	outFree	int64&		Free space on the filesystem, in bytes
←	outAvailable	int64&		Free space available to a non-privileged process (may be equal or less than outFree)

ConvertPathToAbsolute

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Makes the path absolute, inStartPath + inPath

Syntax

```
void avl::ConvertPathToAbsolute
(
 const atl::String& inPath,
 const atl::Optional<atl::Directory> inStartPath,
 atl::String& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const String&		relative path
→	inStartPath	const Optional<Directory>	NIL	starting path, by default the path of the project or where the program was executed in case of AVL
←	outPath	String&		the resulting absolute path

ConvertPathToRelative

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Makes the path relative to inBasePath

Syntax

```
void avl::ConvertPathToRelative
(
 const atl::String& inPath,
 const atl::Optional<atl::Directory> inBasePath,
 atl::String& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const String&		absolute path
→	inBasePath	const Optional<Directory>	NIL	base path, by default the path of the project or where the program was executed in case of AVL
←	outPath	String&		the resulting relative path

CopyFiles

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Copies files that match a pattern from a directory to other directory.

Syntax

```
void avl::CopyFiles
(
 const atl::Directory& inStartDirectory,
 const atl::String& inMask,
 const atl::Directory& inOutputDirectory,
 bool inProcessSubdirectories,
 bool inOverwrite,
 bool& outSuccess
)
```

Parameters

	Name	Type	Default	Description
→	inStartDirectory	const Directory&		
→	inMask	const String&		Wildcard pattern
→	inOutputDirectory	const Directory&		
→	inProcessSubdirectories	bool		
→	inOverwrite	bool		
←	outSuccess	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	inMask needs to be filled in CopyFiles.
DomainError	inOutputDirectory needs to be filled in CopyFiles.
DomainError	inStartDirectory needs to be filled in CopyFiles.

CreateDirectories

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a directory tree if it does not exist.

Syntax

```
void avl::CreateDirectories
(
 const atl::Directory& inDirectory,
 bool& outSuccess
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outSuccess	bool&		

FileAttributes

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Provides information about file, e.g. size, modification time

Syntax

```
void avl::FileAttributes
(
 const atl::File& inFile,
 int& outSizeInKBytes,
 atl::int64& outSizeInBytes,
 bool& outIsReadOnly,
 atl::String& outAccessTime,
 atl::String& outModificationTime,
 atl::String& outCreationTime,
 atl::int64& outAccessTimeValue,
 atl::int64& outModificationTimeValue,
 atl::int64& outCreationTimeValue
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Input file
←	outSizeInKBytes	int&		File size in kilobytes
←	outSizeInBytes	int64&		File size in bytes
←	outIsReadOnly	bool&		Flag indicating whether the file is read-only
←	outAccessTime	String&		File access time
←	outModificationTime	String&		File modification time
←	outCreationTime	String&		File creation time, 0 on unix systems
←	outAccessTimeValue	int64&		File access time value
←	outModificationTimeValue	int64&		File modification time value
←	outCreationTimeValue	int64&		File creation time value, 0 on unix systems

Remarks

Linux

File creation time is unavailable when running AVL on Linux due to file system restrictions. It will always report value 0 which translates to the following time: 1970-01-01T01:00:00.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

FileChecksum

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns CRC checksum of the input file.

Syntax

```
void avl::FileChecksum
(
 const atl::File& inFile,
 atl::String& outChecksum
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
←	outChecksum	String&		

Also in AVL Lite

FindDirectories

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns subdirectories of the input directory.

Syntax

```
void avl::FindDirectories
(
 const atl::Directory& inStartDirectory,
 bool inRecursive,
 atl::Optional<avl::FileSortingOrder::Type> inSortingOrder,
 atl::Array<atl::Directory>& outDirectories,
 bool& outFound = atl::Dummy<bool>()
)
```

Parameters

	Name	Type	Default	Description
→	inStartDirectory	const Directory&	\".\"	
→	inRecursive	bool		
→	inSortingOrder	Optional<FileSortingOrder::Type>	NIL	Sorting order
←	outDirectories	Array<Directory>&		
←	outFound	bool&	Dummy<bool> ()	

Errors

List of possible exceptions:

Error type	Description
IoError	Given start directory is invalid in FindDirectories.

FindFiles

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns files of the input directory.

Syntax

```
void avl::FindFiles
(
 const atl::Directory& inStartDirectory,
 const atl::String& inMask,
 bool inSubdirs,
 atl::Optional<avl::FileSortingOrder::Type> inSortingOrder,
 atl::Array<atl::File>& outFilePaths,
 atl::Array<atl::String>& outFileNames,
 bool& outFound = atl::Dummy<bool>()
)
```

Parameters

	Name	Type	Default	Description
→	inStartDirectory	const Directory&	\".\"	Input directory
→	inMask	const String&	\"*\"	Wildcard pattern
→	inSubdirs	bool		Read subdirectories
→	inSortingOrder	Optional<FileSortingOrder::Type>	NIL	Sorting order
←	outFilePaths	Array<File>&		File paths
←	outFileNames	Array<String>&		File names
←	outFound	bool&	Dummy<bool>()	

Remarks

Working with Find Files

Start with defining a directory path in **inStartDirectory** port to choose where you want to look for files. To search files in subdirectories set **inSubdirs** to 'true'.

inMask pattern string

Port **inMask** specifies wildcard pattern that selects files this filter will operate on. Supported wildcards:

- * - any string of characters, including no characters
- ? - exactly one character

You can use any expression like examples below:

Examples:

- * - all files,
- *.jpg - files only with extension .jpg,
- Filename.* - files with name "Filename" and any extension, including no extension e.g. "Filename."
- Filename.?? - files with name "Filename" and two letter extension,

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	Given start directory is invalid in FindFiles.

See Also

- TestFileExists - Checks if a given file is present.

JoinPathParts

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Joins path parts

Syntax

```
void avl::JoinPathParts
(
 const atl::String& inPath1,
 const atl::String& inPath2,
 const atl::Optional<atl::String>& inPath3,
 const atl::Optional<atl::String>& inPath4,
 atl::String& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath1	const String&		First input path
→	inPath2	const String&		Second input path
→	inPath3	const Optional<String>&	NIL	
→	inPath4	const Optional<String>&	NIL	
←	outPath	String&		Output path

RemoveFile_ByDiskUsage

Header: STD.h
Namespace: avl
Module: FoundationLite

Removes files sorted by size until disk usage drops below the specified threshold.

Syntax

```
void avl::RemoveFile_ByDiskUsage
(
 const atl::Directory& inDirectory,
 float inMaxDiskUsage,
 const avl::SortingOrder::Type& inSortingOrder,
 const atl::String& inMask,
 const avl::FileNameFilter::Type& inMaskType,
 bool inRecursive,
 bool inRemoveDirectories,
 atl::Array<atl::File>& outRemoved,
 atl::int64& outRemovedSize
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDirectory	const Directory&			Directory from which the files will be deleted
→	inMaxDiskUsage	float	0.0 – 1.0	0.8f	Maximum allowed disk usage (0.0 – 1.0). Files are removed until usage drops below this value
→	inSortingOrder	const SortingOrder::Type&		Descending	Sorting order by file size. Descending starts from biggest files, Ascending from smallest
→	inMask	const String&		\"*\"	Filter pattern
→	inMaskType	const FileNameFilter::Type&		Wildcard	Filter type to use with the mask
→	inRecursive	bool		False	Process subdirectories recursively
→	inRemoveDirectories	bool		True	Specifies whether to also delete directories that become empty after files are deleted from them
←	outRemoved	Array<File>&			List of actually deleted entries
←	outRemovedSize	int64&			Size of the deleted files in bytes

Errors

List of possible exceptions:

Error type	Description
DomainError	inMaxDiskUsage must be in range [0.0, 1.0].

Also in AVL Lite

RemoveFile_ByTime

Header: STD.h
Namespace: avl
Module: FoundationLite

Removes files older than the specified timestamp from a directory.

Syntax

```
void avl::RemoveFile_ByTime
(
 const atl::Directory& inDirectory,
 const avl::Timestamp& inTimestamp,
 const atl::String& inMask,
 const avl::FileTimeVariant::Type& inTimeVariant,
 const avl::FileNameFilter::Type& inMaskType,
 bool inRecursive,
 bool inRemoveDirectories,
 atl::Array<atl::File>& outRemoved,
 atl::int64& outRemovedSize
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		Directory from which the files will be deleted
→	inTimestamp	const Timestamp&		Timestamp to compare files to
→	inMask	const String&	\"*\"	Filter pattern
→	inTimeVariant	const FileTimeVariant::Type&	ModificationTime	Variant of the time attribute to use
→	inMaskType	const FileNameFilter::Type&	Wildcard	Filter type to use with the mask
→	inRecursive	bool	False	Process subdirectories recursively
→	inRemoveDirectories	bool	True	Specifies whether to also delete directories that become empty after files are deleted from them
←	outRemoved	Array<File>&		List of actually deleted entries
←	outRemovedSize	int64&		Size of the deleted files in bytes

Remarks

inMask pattern string

Port **inMask** specifies wildcard pattern that selects files this filter will operate on. Supported wildcards:

- * - any string of characters, including no characters
- ? - exactly one character

You can use any expression like examples below:

Examples:

- * - all files,
- *.jpg - files only with extension .jpg,
- Filename.* - files with name "Filename" and any extension, including no extension e.g. "Filename."
- Filename.?? - files with name "Filename" and two letter extension,

Using regular expressions

When port **inMaskType** is set to Regex, the **inMask** port is interpreted as a regular expression pattern rather than a wildcard. The ECMAScript regular expression grammar is used. See some examples of regular expression patterns below:

Regex patterns examples:

- .* - all files,
- .*\.jpg - files only with extension .jpg,
- Filename\..* - files with name "Filename" and any extension, including no extension e.g. "Filename."
- Filename\..{2} - files with name "Filename" and two letter extension,

Specifying the time

The **inTimestamp** port must be set to a Timestamp with the desired value. **DateTimeToTimestamp** filter can be used to create such an object.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- FindFiles - Returns files of the input directory.
- DateTimeToTimestamp - Converts date and time to UTC timestamp.

RemoveFile_Multiple

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Removes files that match a pattern from a directory.

Syntax

```
void avl::RemoveFile_Multiple
(
 const atl::Directory& inStartDirectory,
 const atl::String& inMask,
 bool inProcessSubdirectories,
 bool& outSuccess
)
```

Parameters

	Name	Type	Default	Description
→	inStartDirectory	const Directory&		Path to the directory from which the files are to be deleted
→	inMask	const String&		Wildcard pattern
→	inProcessSubdirectories	bool		Process subdirectories recursively
←	outSuccess	bool&		Whether the deletion was successful or not

Remarks

inMask pattern string

Port **inMask** specifies wildcard pattern that selects files this filter will operate on. Supported wildcards:

- * - any string of characters, including no characters
- ? - exactly one character

You can use any expression like examples below:

Examples:

- * - all files,
- *.jpg - files only with extension .jpg,
- Filename.* - files with name "Filename" and any extension, including no extension e.g. "Filename."
- Filename.?? - files with name "Filename" and two letter extension,

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	inMask needs to be filled in
DomainError	inStartDirectory needs to be filled in

See Also

- FindFiles - Returns files of the input directory.

RemoveFile_Single

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Removes single file.

Syntax

```
void avl::RemoveFile_Single
(
 const atl::File& inFile,
 bool& outSuccess
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Path to the file to delete
←	outSuccess	bool&		Whether the deletion was successful or not

Remarks

inMask pattern string

Port **inMask** specifies wildcard pattern that selects files this filter will operate on. Supported wildcards:

- * - any string of characters, including no characters
- ? - exactly one character

You can use any expression like examples below:

Examples:

- * - all files,
- *.jpg - files only with extension .jpg,
- Filename.* - files with name "Filename" and any extension, including no extension e.g. "Filename."
- Filename.?? - files with name "Filename" and two letter extension,

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	inFile does not exist in RemoveFile.
IoError	inFile is not a normal file in RemoveFile.

See Also

- FindFiles - Returns files of the input directory.

SplitFileNameToParts

Header: STD.h
Namespace: avl
Module: FoundationLite

Splits the filename to base and extension, the extension is considered

Syntax

```
void avl::SplitFileNameToParts
(
 const atl::String& inPath,
 atl::String& outNameBase,
 atl::String& outExtension
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const String&		Input path
←	outNameBase	String&		
←	outExtension	String&		

SplitPathToNameParent

Header: STD.h
Namespace: avl
Module: FoundationLite

Splits a file path into a file name and a parent directory

Syntax

```
void avl::SplitPathToNameParent
(
 const atl::String& inPath,
 atl::String& outRoot,
 atl::String& outName
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const String&		input path
←	outRoot	String&		the parent path
←	outName	String&		name, directory or file

SplitPathToParts

Header: STD.h
Namespace: avl
Module: FoundationLite

Determines the information about the filesystem on which the pathname inPath is located.

Syntax

```
void avl::SplitPathToParts
(
 const atl::String& inPath,
 atl::Array<atl::String>& outPathParts
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const String&		Input path
←	outPathParts	Array<String>&		

TestDirectoryEmpty

Header: STD.h
Namespace: avl
Module: FoundationLite

Checks if a given directory is empty.

Syntax

```
void avl::TestDirectoryEmpty
(
 const atl::Directory& inDirectory,
 bool& outEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outEmpty	bool&		

Errors

List of possible exceptions:

Error type	Description
IoError	Directory does not exist in TestDirectoryEmpty
IoError	Path is not a directory in TestDirectoryEmpty

TestDirectoryExists

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Checks if a given directory is present.

Syntax

```
void avl::TestDirectoryExists
(
 const atl::Directory& inDirectory,
 bool& outExists
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outExists	bool&		

Errors

List of possible exceptions:

Error type	Description
IoError	Path is not a directory in TestDirectoryExists

TestFileEmpty

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Checks if the size of the file is equal to zero.

Syntax

```
void avl::TestFileEmpty
(
 const atl::File& inFile,
 bool& outEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
←	outEmpty	bool&		

Errors

List of possible exceptions:

Error type	Description
IoError	File does not exist in TestFileEmpty
IoError	Path does not point to a file in TestFileEmpty

TestFileExists

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Checks if a given file is present.

Syntax

```
void avl::TestFileExists
(
 const atl::File& inFile,
 bool& outSuccess
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&

FillImageBuffer

Header: AVL.h
Namespace: avl
Module: FoundationLite

Fills image buffer with provided data.

Syntax

```
 avl::FillImageBuffer
(
 avl::Image& inImage,
 int inWidth,
 int inHeight,
 avl::PlainType::Type inType,
 int inDepth,
 int inPitch,
 atl::byte * inData
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	Image&		
➡	inWidth	int		
➡	inHeight	int		
➡	inType	PlainType::Type		
➡	inDepth	int		
➡	inPitch	int		
➡	inData	byte *		

Also in AVL Lite

FillImagePreviewBuffer

Header: AVL.h
Namespace: avl
Module: FoundationLite

Fills image buffer with provided data.

Syntax

```
 avl::FillImagePreviewBuffer
(
 avl::Image& inImage,
 int inPreviewWidth,
 int inPreviewHeight,
 atl::byte* inBuffer,
 int inBufferStride,
 int inPitch,
 atl::byte * inData
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	Image&		
➡	inPreviewWidth	int		
➡	inPreviewHeight	int		
➡	inBuffer	byte*		
➡	inBufferStride	int		
➡	inPitch	int		
➡	inData	byte *		

Also in AVL Lite

EnumerateImages

Header: AVL.h
Namespace: avl
Module: FoundationLite

Scans a disk directory for image files and then returns the images one by one in consecutive iterations sorted according to the specified order.

Applications: Emulates image acquisition with images stored on disk.

Syntax

```
bool avl::EnumerateImages
(
 EnumerateFilesState& ioState,
 const atl::Directory& inDirectory,
 atl::Optional<avl::ImageFileFormat::Type> inFileType,
 avl::FileSortingOrder::Type inSortingOrder,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 bool inLoadAlphaChannel,
 const int inDelay,
 avl::Image& outImage,
 atl::File& outFilePath,
 atl::String& outFileName,
 atl::Optional<bool&> outIsFirst = atl::NIL,
 atl::Optional<bool&> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	EnumerateFilesState&		Object used to maintain state of the function.
→	inDirectory	const Directory&	\".\"	Input directory
→	inFileType	Optional<ImageFileFormat::Type>	NIL	File format of the images
→	inSortingOrder	FileSortingOrder::Type		Sorting order
→	inRepeat	bool		Determines whether to repeat reading directory after reading all files
→	inProcessSubdirectories	bool		Flag indicating whether to load images from the subdirectories or not
→	inInvert	bool		Flag indicating whether to enumerate images backwards or not
→	inLoadAlphaChannel	bool		Flag indicating whether to load alpha channel of the image or not
→	inDelay	const int		Minimum time between iterations in milliseconds
←	outImage	Image&		Output image
←	outFilePath	File&		Output file path
←	outFileName	String&		Output file name
←	outIsFirst	Optional<bool&>	NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool&>	NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Hints

- Set **inDirectory** to specify where on your disk are the images you want to load.
- This filter can also be added easily by dragging and dropping a disk directory from Windows Explorer to the Program Editor in Aurora Vision Studio.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

EnumerateImages_Random

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Scans a disk directory for image files and then returns the images one by one in consecutive iterations sorted randomly.

Applications: Emulates image acquisition with images stored on disk.

Syntax

```
bool avl::EnumerateImages_Random
(
 EnumerateFilesRandomState& ioState,
 const atl::Directory& inDirectory,
 atl::Optional<avl::ImageFileFormat::Type> inFileType,
 atl::Optional<int> inSeed,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 bool inLoadAlphaChannel,
 const int inDelay,
 avl::Image& outImage,
 atl::File& outFilePath,
 atl::String& outFileName,
 atl::Optional<bool&> outIsFirst = atl::NIL,
 atl::Optional<bool&> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	EnumerateFilesRandomState&		Object used to maintain state of the function.
→	inDirectory	const Directory&	\".\"	Input directory
→	inFileType	Optional<ImageFileFormat::Type>	NIL	File format of the images
→	inSeed	Optional<int>	NIL	Random seed used to determine random sorting order
→	inRepeat	bool		Determines whether to repeat reading directory after reading all files
→	inProcessSubdirectories	bool		Flag indicating whether to load images from the subdirectories or not
→	inInvert	bool		Flag indicating whether to enumerate images backwards or not
→	inLoadAlphaChannel	bool		Flag indicating whether to load alpha channel of the image or not
→	inDelay	const int		Minimum time between iterations in milliseconds
←	outImage	Image&		Output image
←	outFilePath	File&		Output file path
←	outFileName	String&		Output file name
←	outIsFirst	Optional<bool&>	NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool&>	NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Also in AVL Lite

GetAvailableVideoCompressors

Header: AVL.h
Namespace: avl
Module: FoundationLite

Lists FourCC names of available video compressors.

Syntax

```
void avl::GetAvailableVideoCompressors
(
 atl::Array<atl::String>& outCompressors
)
```

Parameters

	Name	Type	Default	Description
←	outCompressors	Array<String>&		Available compressors.

Also in AVL Lite

GrabImage_FromFiles

Header: AVL.h
Namespace: avl
Module: FoundationLite

Simulates capturing a frame from a camera.

Applications: Can be used as EnumerateImages, but its state is global in a program - does not reset when some task is finished.

Syntax

```
bool avl::GrabImage_FromFiles
(
 const atl::Directory& inDirectory,
 atl::Optional<avl::ImageFileFormat::Type> inFileType,
 avl::FileSortingOrder::Type inSortingOrder,
 bool inRepeat,
 bool inProcessSubdirectories,
 bool inInvert,
 bool inLoadAlphaChannel,
 int inDelay,
 avl::Image& outImage,
 atl::File& outFilePath,
 atl::String& outFileName
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDirectory	const Directory&		\".\"	Input directory
→	inFileType	Optional<ImageFileFormat::Type>		NIL	File format of the images
→	inSortingOrder	FileSortingOrder::Type			Sorting order
→	inRepeat	bool			Determines whether to repeat reading directory after reading all files
→	inProcessSubdirectories	bool			Flag indicating whether to load images from the subdirectories or not
→	inInvert	bool			Flag indicating whether to enumerate images backwards or not
→	inLoadAlphaChannel	bool			Flag indicating whether to load alpha channel of the image or not
→	inDelay	int	0 - 2000		
←	outImage	Image&			Output image
←	outFilePath	File&			Output file path
←	outFileName	String&			Output file name

Description

This filter works similarly to EnumerateImages, but it behaves more like a camera: it preserves its state across the whole program.

For example, you can have two GrabImage_FromFiles filters in two different Task macrofilters. When execution of second Task starts, images loaded previously in the first Task are not loaded again.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	All instances of GrabImage_FromFiles must have these same parameters.

See Also

- EnumerateImages – Scans a disk directory for image files and then returns the images one by one in consecutive iterations sorted according to the specified order.

Also in **AVL Lite**

GrabImage_FromFiles_ResetState

Header: AVL.h
Namespace: avl
Module: FoundationLite

Resets the global state of GrabImage_FromFiles filter.

Syntax

```
void avl::GrabImage_FromFiles_ResetState()
```

Also in **AVL Lite**

GrabScreenshot

Header: AVL.h
Namespace: avl
Module: FoundationLite

Grabs a screenshot of the Desktop.

Syntax

```
void avl::GrabScreenshot
(
 const atl::Optional<avl::Box>& inSelection,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inSelection	const Optional<Box>&	NIL	Bounding box of screen area to capture, whole desktop if not specified.
←	outImage	Image&		Desktop screenshot image

Platform support

This operation is only supported on the Microsoft Windows operating system.

LoadImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads a single image from a file.

Syntax

```
void avl::LoadImage
(
 const atl::File& inFile,
 bool inLoadAlphaChannel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Path to a file
→	inLoadAlphaChannel	bool		Whether to load the alpha channel (if exists) as an additional image channel
←	outImage	Image&		Output image

Description

The operation loads an image from a file in one of the standard image file formats. Currently the filter supports the following formats:

- BMP (*.bmp),
- JPEG (*.jpg, *jpeg),
- PNG (*.png),
- PNM (*.pbm, *.pgm, *.ppm, *.pnm),
- TIFF (*.tif, *.tiff).

The format of the image file is recognized automatically based on the file header.

The resulting **outImage** will be three-channel image of UInt8 pixel type, or sometimes of UInt16 pixel type for 16-bit depth images of supported formats (PNG, TIFF).

Hints

- Set **inFile** to specify a path to the image file you want to load.
- This filter can also be added easily by dragging and dropping an image file from Windows Explorer to the Program Editor in Aurora Vision Studio.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image is damaged or it is not a BMP, PNG, PNM, TIF or JPG file in LoadImage. File: File name Unable to open an image. Image header format is unrecognized. Image format is unknown or image is damaged. Load image supports only BMP, PNG, PNM, JPG and TIFF formats.

See Also

- SaveImage – Saves an image to a file.

LoadImageFormat

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads a single image format from a file without loading all image data.

Syntax

```
void avl::LoadImageFormat
(
 const atl::File& inFile,
 bool inLoadAlphaChannel,
 avl::ImageFormat& outImageFormat
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Path to a file
→	inLoadAlphaChannel	bool		
←	outImageFormat	ImageFormat&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Image is damaged or it is not a BMP, PNG, PNM, TIF or JPG file in LoadImageFormat. File: File name Unable to open an image. Image header format is unrecognized. Image format is unknown or image is damaged. Load image supports only BMP, PNG, PNM, JPG and TIFF formats.

LoadImageFromBuffer

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads a single image from a file stored in memory.

Applications: Use this filter when you received an image file through I/O communication, e.g. through a TcpIp connection.

Syntax

```
void avl::LoadImageFromBuffer
(
 const avl::ByteBuffer& inBuffer,
 int inOffset,
 atl::Optional<int> inLength,
 bool inLoadAlphaChannel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inBuffer	const ByteBuffer&		Source buffer containing image file data
→	inOffset	int	0	Image data start position in source buffer
→	inLength	Optional<int>	NIL	Image data length in source buffer
→	inLoadAlphaChannel	bool		Whether to load the alpha channel (if exists) as an additional image channel
←	outImage	Image&		Output image

Description

This function loads an Image from a common format file similarly to LoadImage, but instead of accessing the file system it uses only the memory by loading the file content from ByteBuffer.

The operation loads an image from a file in one of the standard image file formats. Currently the filter supports the following formats:

- BMP (*.bmp),
- JPEG (*.jpg, *jpeg),
- PNG (*.png),
- PNM (*.pbm, *.pgm, *.ppm, *.pnm),
- TIFF (*.tif, *.tiff).

The format of the image file is recognized automatically based on the file header.

The resulting **outImage** will be three-channel image of UInt8 pixel type, or sometimes of UInt16 pixel type for 16-bit depth images of supported formats (PNG, TIFF).

Errors

List of possible exceptions:

Error type	Description
IoError	Reading beyond the end of the byte buffer in LoadImageFromBuffer.

See Also

- SaveImageToBuffer – Saves an image to a file stored in ByteBuffer.
- LoadImage – Loads a single image from a file.

LoadMultiplePagesTiffImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads a image array from a tiff file.

Syntax

```
void avl::LoadMultiplePagesTiffImage
(
 const atl::File& inFile,
 bool inLoadAlphaChannel,
 atl::Array<avl::Image>& outImages
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Path to a file
→	inLoadAlphaChannel	bool		Whether to load the alpha channel (if exists) as an additional image channel
←	outImages	Array<Image>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Image is damaged or it is not a TIF file in LoadMultiplePagesTiffImage. File: File name Unable to open an image. Image header format is unrecognized. Image format is unknown or image is damaged. Load image supports only TIFF formats.

OpenInputVideoStream

Header: AVL.h
Namespace: avl
Module: FoundationLite

Opens and creates a video stream from a file.

Syntax

```
void avl::OpenInputVideoStream
(
 const atl::File& inFile,
 int inStartFrame,
 avl::InputVideoStream& outInputVideoStream,
 float& outFPS,
 int& outMaxFrame
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Video file
→	inStartFrame	int		Number of first frame to fetch.
←	outInputVideoStream	InputVideoStream&		Initialized input video stream
←	outFPS	float&		Frames per second
←	outMaxFrame	int&		Last frame number

Platform support

This operation is only supported on the Microsoft Windows operating system.

Errors

List of possible exceptions:

Error type	Description
DomainError	Function not available under the linux.
DomainError	Negative start frame in OpenInputVideoStream.
DomainError	Start frame too high for current video in OpenInputVideoStream.
RuntimeError	Unexpected error in OpenInputVideoStream.

OpenOutputVideoStream

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a video stream which will be saved to a selected file.

Syntax

```
void avl::OpenOutputVideoStream
(
 const atl::File& inFile,
 const avl::VideoEncoder::Type inVideoEncoder,
 const float inFPS,
 const int inFrameWidth,
 const int inFrameHeight,
 avl::OutputVideoStream& outOutputVideoStream
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		File path of the output file
→	inVideoEncoder	const VideoEncoder::Type		Video encoder
→	inFPS	const float		Desired frame rate of the produced video file
→	inFrameWidth	const int		Width of frame being added
→	inFrameHeight	const int		Height of frame being added
←	outOutputVideoStream	OutputVideoStream&		Initialized output video stream

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported Video Encoder in OpenOutputVideoStream.

OpenOutputVideoStream_Any

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a video stream which will be saved to a selected file.

Syntax

```
void avl::OpenOutputVideoStream_Any
(
 const atl::File& inFile,
 const avl::VideoEncoderName& inVideoEncoderName,
 const float inFPS,
 const int inFrameWidth,
 const int inFrameHeight,
 avl::OutputVideoStream& outOutputVideoStream
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		File path of the output file
→	inVideoEncoderName	const VideoEncoderName&		Video encoder
→	inFPS	const float		Desired frame rate of the produced video file
→	inFrameWidth	const int		Width of frame being added
→	inFrameHeight	const int		Height of frame being added
←	outOutputVideoStream	OutputVideoStream&		Initialized output video stream

ReadVideoStream

Header: AVL.h
Namespace: avl
Module: FoundationLite

Acquires a frame from a previously opened video stream.

Syntax

```
bool avl::ReadVideoStream
(
 const avl::InputVideoStream& inInputVideoStream,
 bool inRepeat,
 int& outFrameNum,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inInputVideoStream	const InputVideoStream&		Previously opened input video stream
→	inRepeat	bool		Determines whether to repeat video playback
←	outFrameNum	int&		Current frame number
←	outImage	Image&		Current frame

Platform support

This operation is only supported on the Microsoft Windows operating system.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrectly initialized InputVideoStream object passed to ReadVideoStream

SaveImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a file.

Syntax

```
void avl::SaveImage
(
 const avl::Image& inImage,
 atl::Optional<avl::ImageFileFormat::Type> inImageFileFormat,
 const atl::File& inFile,
 bool inIgnoreErrors = false
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	const Image&		An image to be saved
➡	inImageFileFormat	Optional<ImageFileFormat::Type>	NIL	If Nil the format will be chosen on the basis of extension
➡	inFile	const File&		Path to a file
➡	inIgnoreErrors	bool	false	Switches to re-trying and canceling in case of errors (e.g. when the disk is full)

Description

The operation saves an image to file encoded in one of the standard image file formats. Currently the filter supports the following formats:

- BMP (*.bmp)
- JPEG (*.jpg, *jpeg)
- PNG (*.png),
- PNM (*.pbm, *.pgm, *.ppm, *.pnm),
- TIFF (*.tif, *.tiff).

Because of the limitations of the standard image formats, the filter is capable of saving three-channel images of UInt8 pixel type for all formats, and UInt16 for supported formats only (PNG, TIFF). To alter the format of an image one can use the filters contained in the Image Conversions category.

The **inImageFileFormat** input can be used to explicitly select the file format to be used. When **inImageFileFormat** is set to Auto the recognition of the desired image file format is based on the extension of the file being written, so it is essential that the extension is present and accurate. When extension of the file is not specified, it will be appended according to **inImageFileFormat**.

If the selected file does not exist, it will be created on filter execution. If the selected file does exist, it will be overwritten.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported pixel type in SaveImage.

See Also

- LoadImage – Loads a single image from a file.
- SaveImage_Asynchronous – Saves an image to a file in the background thread.

SaveImageToBuffer

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a file stored in ByteBuffer.

Applications: Use this filter if you want to send image file through I/O communication, e.g. through a TcpIp connection.

Syntax

```
void avl::SaveImageToBuffer
(
 const avl::Image& inImage,
 avl::ImageFileFormat::Type inImageFileFormat,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		An image to be saved
→	inImageFileFormat	ImageFileFormat::Type		Image file format
←	outBuffer	ByteBuffer&		Buffer containing image file data

Description

This function saves an Image to a common format file similarly to SaveImage, but instead of accessing the file system it stores the file in the memory by writing its content to ByteBuffer.

The operation saves an image to file encoded in one of the standard image file formats. Currently the filter supports the following formats:

- BMP (*.bmp)
- JPEG (*.jpg, *jpeg)
- PNG (*.png),
- PNM (*.pbm, *.pgm, *.ppm, *.pnm),
- TIFF (*.tif, *.tiff).

Because of the limitations of the standard image formats, the filter is capable of saving three-channel images of UInt8 pixel type for all formats, and UInt16 for supported formats only (PNG, TIFF). To alter the format of an image one can use the filters contained in the Image Conversions category.

See Also

- SaveImage – Saves an image to a file.
- LoadImageFromBuffer – Loads a single image from a file stored in memory.

SaveImageToJpeg

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a JPEG file.

Syntax

```
void avl::SaveImageToJpeg
(
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<int> inQuality,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			An image to be saved
➡	inFile	const File&			Path to a file
➡	inQuality	Optional<int>	0 – 100	NIL	Quality
➡	inIgnoreErrors	bool			Switches to re-trying and canceling in case of errors (e.g. when the disk is full)

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in SaveImageToJpeg. Supported formats: UInt8, UInt16.

SaveImageToJpeg_Asynchronous

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a JPEG file in the background thread.

Syntax

```
void avl::SaveImageToJpeg_Asynchronous
(
 SaveImageState& ioState,
 int inThreadQueueSize,
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<int> inQuality,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SaveImageState&			Object used to maintain state of the function.
	inThreadQueueSize	int	1 – ∞	3	Number of incoming frames that can be buffered before the thread is able to process them
	inImage	const Image&			An image to be saved
	inFile	const File&			Path to a file
	inQuality	Optional<int>	0 – 100	NIL	Quality
	inIgnoreErrors	bool			If false the error will be reported as soon as the filter instance is again executed

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16.

Read more about pixel formats in Image documentation.

Remarks

This filter is executed in the background thread. Execution errors may be reported with a delay or ignored. Stopping of the program may be delayed, because of waiting for background work to complete.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in SaveImageToJpeg_Asynchronous. Supported formats: UInt8, UInt16.

See Also

- LoadImage – Loads a single image from a file.
- SaveImage – Saves an image to a file.

SaveImageToPng

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a PNG file.

Syntax

```
void avl::SaveImageToPng
(
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<int> inCompressionLevel,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			An image to be saved
➡	inFile	const File&			Path to a file
➡	inCompressionLevel	Optional<int>	0 – 9	NIL	Compression level
➡	inIgnoreErrors	bool			Switches to re-trying and canceling in case of errors (e.g. when the disk is full)

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in SaveImageToPng. Supported formats: UInt8, UInt16.

SaveImageToPng_Asynchronous

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a PNG file in the background thread.

Syntax

```
void avl::SaveImageToPng_Asynchronous
(
 SaveImageState& ioState,
 int inThreadQueueSize,
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<int> inCompressionLevel,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SaveImageState&			Object used to maintain state of the function.
	inThreadQueueSize	int	1 – ∞	3	Number of incoming frames that can be buffered before the thread is able to process them
	inImage	const Image&			An image to be saved
	inFile	const File&			Path to a file
	inCompressionLevel	Optional<int>	0 – 9	NIL	Compression level
	inIgnoreErrors	bool			If false the error will be reported as soon as the filter instance is again executed

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16.

Read more about pixel formats in Image documentation.

Remarks

This filter is executed in the background thread. Execution errors may be reported with a delay or ignored. Stopping of the program may be delayed, because of waiting for background work to complete.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in SaveImageToPng_Asynchronous. Supported formats: UInt8, UInt16.

See Also

- LoadImage – Loads a single image from a file.
- SaveImage – Saves an image to a file.

SaveImageToTiff

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a TIFF file.

Syntax

```
void avl::SaveImageToTiff
(
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<avl::TiffImageCompressionScheme::Type> inCompressionScheme,
 atl::Optional<int> inJpegQuality,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			An image to be saved
→	inFile	const File&			Path to a file
→	inCompressionScheme	Optional<TiffImageCompressionScheme::Type>		NIL	Compression scheme
→	inJpegQuality	Optional<int>	0 – 100	NIL	Quality – used only for JPEG compression scheme
→	inIgnoreErrors	bool			Switches to re-trying and canceling in case of errors (e.g. when the disk is full)

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16, real, int32.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Compression is not supported for 32-bit pixel type in SaveImageToTiff.
DomainError	inJpegQuality set in SaveImageToTiff is valid only with inCompressionScheme set as JPEG.
DomainError	Path name cannot be empty in SaveImageToTiff.
DomainError	Not supported inImage pixel format in SaveImageToTiff. Supported formats: UInt8, UInt16, Real, Int32.

SaveImageToTiff_Asynchronous

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a TIFF file in the background thread.

Syntax

```
void avl::SaveImageToTiff_Asynchronous
(
 SaveImageState& ioState,
 int inThreadQueueSize,
 const avl::Image& inImage,
 const atl::File& inFile,
 atl::Optional<avl::TiffImageCompressionScheme::Type> inCompressionScheme,
 atl::Optional<int> inJpegQuality,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SaveImageState&			Object used to maintain state of the function.
	inThreadQueueSize	int	1 – ∞	3	Number of incoming frames that can be buffered before the thread is able to process them
	inImage	const Image&			An image to be saved
	inFile	const File&			Path to a file
	inCompressionScheme	Optional<TiffImageCompressionScheme::Type>		NIL	Compression scheme
	inJpegQuality	Optional<int>	0 – 100	NIL	Quality (0–100) – used only for JPEG compression scheme
	inIgnoreErrors	bool			If false the error will be reported as soon as the filter instance is again executed

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16, real, int32.

Read more about pixel formats in Image documentation.

Remarks

This filter is executed in the background thread. Execution errors may be reported with a delay or ignored. Stopping of the program may be delayed, because of waiting for background work to complete.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Compression is not supported for 32-bit pixel type in SaveImageToTiff_Asynchronous.
DomainError	inJpegQuality set in SaveImageToTiff_Asynchronous is valid only with inCompressionScheme set as JPEG.
DomainError	Path name cannot be empty in SaveImageToTiff_Asynchronous.
DomainError	Not supported inImage pixel format in SaveImageToTiff_Asynchronous. Supported formats: UInt8, UInt16, Real, Int32.

See Also

- LoadImage – Loads a single image from a file.
- SaveImage – Saves an image to a file.

SaveImage_Asynchronous

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves an image to a file in the background thread.

Syntax

```
void avl::SaveImage_Asynchronous
(
 SaveImageState& ioState,
 int inThreadQueueSize,
 const avl::Image& inImage,
 atl::Optional<avl::ImageFileFormat::Type> inImageFileFormat,
 const atl::File& inFile,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SaveImageState&			Object used to maintain state of the function.
	inThreadQueueSize	int	1 – ∞	3	Number of incoming frames that can be buffered before the thread is able to process them
	inImage	const Image&			An image to be saved
	inImageFileFormat	Optional<ImageFileFormat::Type>		NIL	If Nil the format will be chosen on the basis of extension
	inFile	const File&			Path to a file
	inIgnoreErrors	bool			If false the error will be reported as soon as the filter instance is again executed

Description

The operation saves an image to file encoded in one of the standard image file formats. Currently the filter supports the following formats:

- BMP (*.bmp)
- JPEG (*.jpg, *jpeg)
- PNG (*.png),
- PNM (*.pbm, *.pgm, *.ppm, *.pnm),
- TIFF (*.tif, *.tiff).

Because of the limitations of the standard image formats, the filter is capable of saving three-channel images of UInt8 pixel type for all formats, and UInt16 for supported formats only (PNG, TIFF). To alter the format of an image one can use the filters contained in the Image Conversions category.

The **inImageFileFormat** input can be used to explicitly select the file format to be used. When **inImageFileFormat** is set to Auto the recognition of the desired image file format is based on the extension of the file being written, so it is essential that the extension is present and accurate. When extension of the file is not specified, it will be appended according to **inImageFileFormat**.

If the selected file does not exist, it will be created on filter execution. If the selected file does exist, it will be overwritten.

Remarks

This filter is executed in the background thread. Execution errors may be reported with a delay or ignored. Stopping of the program may be delayed, because of waiting for background work to complete.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported pixel type in SaveImage_Asynchronous.

See Also

- LoadImage – Loads a single image from a file.
- SaveImage – Saves an image to a file.

WriteVideoStream

Header: AVL.h
Namespace: avl
Module: FoundationLite

Writes an image to a previously opened video stream.

Syntax

```
void avl::WriteVideoStream
(
 const avl::OutputVideoStream& inOutputVideoStream,
 const avl::Image& inImage
)
```

Parameters

	Name	Type	Default	Description
➡	inOutputVideoStream	const OutputVideoStream&		Previously opened output video stream
➡	inImage	const Image&		Frame to be added to stream

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrectly initialized OutputVideoStream object passed to WriteVideoStream
DomainError	Incorrectly OutputVideoStream object passed to WriteVideoStream

DecodeVideo

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from video file with using FFmpeg library.

Syntax

```
bool avl::DecodeVideo
(
 FFmpeg_DecoderState& ioState,
 const atl::File& inFile,
 const atl::Optional<atl::int64> inStartFrameId,
 avl::Image& outImage,
 atl::int64& outFrameId
)
```

Parameters

	Name	Type	Default	Description
	ioState	FFmpeg_DecoderState&		Object used to maintain state of the function.
	inFile	const File&		File path with the appropriate format, e.g., input.avi
	inStartFrameId	const Optional<int64>	NIL	ID of the frame to start the acquisition
	outImage	Image&		Captured frame
	outFrameId	int64&		ID of the captured frame

Remarks

To use this filter it is required to install FFmpeg software.

FFmpeg can be downloaded from the following website: https://ffmpeg.org/download.html. Please download the "shared" version of the FFmpeg, but it might be compiled with non-free GPL flags. You can check built options writing in the console *ffmpeg -version*.

If downloaded version contains non-free elements you will have to upgrade FFmpeg license (contact FFmpeg) or build it from sources with appropriate flags:

```
./configure --disable-gpl --enable-version3 --disable-nonfree \
            --enable-shared --disable-static \
            --disable-encoder=libx264 --disable-encoder=libx265 --disable-encoder=libxvid \
            --enable-libopenjpeg \
            --enable-libvpx --enable-encoder=libvpx_vp8 --enable-encoder=libvpx_vp9
```

Recommended FFmpeg version for Aurora Vision Studio usage is **7.1**.

Add DLL path to system environment variable may be required.

Video decoder software

This filter is intended to convert video file to series of images using FFmpeg library.

This filter is not able to decode all video formats supported by FFmpeg.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

EncodeVideo

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Encodes video from images and saves it with using FFmpeg library.

Syntax

```
void avl::EncodeVideo
(
 FFmpeg_EncoderState& ioState,
 const atl::File& inFile,
 const avl::FFmpegCodec::Type& inFourCC,
 const avl::Image& inImage,
 int inFPS
)
```

Parameters

	Name	Type	Default	Description
	ioState	FFmpeg_EncoderState&		Object used to maintain state of the function.
	inFile	const File&		File path with the appropriate format, e.g., output.avi
	inFourCC	const FFmpegCodec::Type&		Codec type for video encoding
	inImage	const Image&		Input image to be encoded
	inFPS	int	20	Frames per second for video encoding

Remarks

To use this filter it is required to install FFmpeg software.

FFmpeg can be downloaded from the following website: https://ffmpeg.org/download.html. Please download the "shared" version of the FFmpeg, but it might be compiled with non-free GPL flags. You can check built options writing in the console *ffmpeg -version*.

If downloaded version contains non-free elements you will have to upgrade FFmpeg license (contact FFmpeg) or build it from sources with appropriate flags:

```
./configure --disable-gpl --enable-version3 --disable-nonfree \
            --enable-shared --disable-static \
            --disable-encoder=libx264 --disable-encoder=libx265 --disable-encoder=libxvid \
            --enable-libopenjpeg \
            --enable-libvpx --enable-encoder=libvpx_vp8 --enable-encoder=libvpx_vp9
```

Recommended FFmpeg version for Aurora Vision Studio usage is **7.1**.

Add DLL path to system environment variable may be required.

Video encoder software

This filter is intended to encode upcoming frames into video using FFmpeg library.

This filter can save videos using following codecs and containers:

- MPEG4 – MP4, AVI, MOV, MKV, 3GP, TS;
- FFV1 – AVI, MOV, NUT;
- OpenJPEG – MKV, MOV, MP4, AVI;
- VP8 – MKV, WEBM, AVI;
- VP9 – MKV, WEBM.

To use this filter, specify the container type in the **inFilename** input, e.g., "SampleVideo.avi".

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

7. String

Table of content:

- ReadObjectFromBase64
- WriteObjectToBase64
- FormatDoubleToString
- FormatIntegerToString
- FormatRealToString
- LoadText
- LoadTextLines
- SaveText
- SaveTextLines

ReadObjectFromBase64

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads element from string stream of specified format.

Syntax

```
void avl::ReadObjectFromBase64
(
 const atl::String& inString,
 Type& outObject
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		Object to be read.
←	outObject	Type&		Read data.

WriteObjectToBase64

Header: STD.h
Namespace: avl
Module: FoundationLite

Encodes object as base64 string.

Syntax

```
void avl::WriteObjectToBase64
(
 const Type& inObject,
 atl::String& outString
)
```

Parameters

	Name	Type	Default	Description
→	inObject	const Type&		Object to be saved
←	outString	String&		Output String

Also in AVL Lite

FormatDoubleToString

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a string from a double number using a proper format.

Applications: Useful for preparing a number for display or communication with specific number of fractional digits, sign etc.

Syntax

```
void avl::FormatDoubleToString
(
 double inDouble,
 const int inIntegerDigitCount,
 const int inFractionalDigitCount,
 const atl::String& inDecimalMark,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDouble	double			Input real
→	inIntegerDigitCount	const int	0 – 1000		How many characters the integer part of the input real should have at least
→	inFractionalDigitCount	const int	0 – 100	3	How many characters the fractional part of the input real should have
→	inDecimalMark	const String&		\".\"	The symbol used to separate the integer part from the fractional part of the number
→	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
→	inForceSignPrinting	const bool		False	Forces printing the sign of the number even if the number is positive
→	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
←	outString	String&			Output string

Examples

→	←
inDouble = 2.7182818284590452 **inIntegerDigitCount** = 2 **inFractionalDigitCount** = 2 **inDecimalMark** = "," **inTrailingCharacter** = "0" **inForceSignPrinting** = False **inSuffix** = "..."	**outString** = "02,72..."

In the first example desired integer digit count equals 2 as entered in **inIntegerDigitCount**, so the filter attaches character in **inTrailingCharacter** (zero) at the beginning of the result **outString**.
Decimal mark is set as a comma and the number of fractional digits as 2.
The result string ends with ellipsis defined in **inSuffix** and the result is "02,72...".
Note that the second digit was rounded up to "2" due to the succeeding digit.

→	←
inDouble = 77 **inIntegerDigitCount** = 1 **inFractionalDigitCount** = 1 **inDecimalMark** = "." **inTrailingCharacter** = "#" **inForceSignPrinting** = True **inSuffix** = "°"	**outString** = "+77.0°"

The second example demonstrates formatting with one integer digit and one fractional. Note that the integer part of the formatted number is less than the value, but it doesn't affect to this part (unlike fractional part which can cuts off excessing digits).
Trailing character (**#**) doesn't affect to anything, because desired integer digit count described by **inIntegerDigitCount** is one (the same effect would be for zero).

Remarks

If you want to cut off excessing digits from a fractional part of a number (instead of rounding them), you can format a number with one extra precision digit and then use Substring to cut off the last digit.
You can add a suffix manually by using AvsFilter_ConcatenateStrings.

Errors

List of possible exceptions:

Error type	Description
DomainError	inDecimalMark has to be a single character in FormatDoubleToString.
DomainError	inTrailingCharacter has to be a single character in FormatDoubleToString.

See Also

- FormatRealToString – Creates a string from a real number using a proper format.
- FormatIntegerToString – Creates a string from an integer number using a proper format.
- FormatString – Creates a string according to the given format and data.

FormatIntegerToString

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a string from an integer number using a proper format.

Applications: Useful for preparing a number for display or communication with specific number of digits, sign etc.

Syntax

```
void avl::FormatIntegerToString
(
 const int inInteger,
 const int inDigitCount,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 const int inSystemBase,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inInteger	const int			Input integer
➡	inDigitCount	const int	0 – 100		How many characters the output string should have at least
➡	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
➡	inForceSignPrinting	const bool		False	Forces printing the sign of the number even if the number is positive
➡	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
➡	inSystemBase	const int	2 – 16	10	The base of the numeral system
⬅	outString	String&			Output string

Examples

➡	⬅
inInteger = 200 **inDigitCount** = 4 **inTrailingCharacter** = "0" **inForceSignPrinting** = False **inSuffix** = "" **inSystemBase** = 16	**outString** = "00C8"

In the above example the input value is 200. Formatting is configured for displaying 4-digit hexadecimal number by setting the **inDigitCount** input. The value of 200 expressed in hexadecimal numeral system is represented as **0xC8**. The final result is filled in with zeros.

➡	⬅
inInteger = 25 **inDigitCount** = 4 **inTrailingCharacter** = "-" **inForceSignPrinting** = False **inSuffix** = "" **inSystemBase** = 10	**outString** = "--25"

The next example shows you how final representation of a number can be filled with arbitrary chosen sign. First two characters are dashes as defined in **inTrailingCharacter**.

Errors

List of possible exceptions:

Error type	Description
DomainError	inTrailingCharacter has to be a single character in FormatIntegerToString.

See Also

- FormatRealToString – Creates a string from a real number using a proper format.
- FormatDoubleToString – Creates a string from a double number using a proper format.
- FormatString – Creates a string according to the given format and data.

FormatRealToString

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a string from a real number using a proper format.

Applications: Useful for preparing a number for display or communication with specific number of fractional digits, sign etc.

Syntax

```
void avl::FormatRealToString
(
 const float inReal,
 const int inIntegerDigitCount,
 const int inFractionalDigitCount,
 const atl::String& inDecimalMark,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inReal	const float			Input real
→	inIntegerDigitCount	const int	0 – 1000		How many characters the integer part of the input real should have at least
→	inFractionalDigitCount	const int	0 – 100	3	How many characters the fractional part of the input real should have
→	inDecimalMark	const String&		\".\"	The symbol used to separate the integer part from the fractional part of the number
→	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
→	inForceSignPrinting	const bool		False	Forces printing the sign of the number even if the number is positive
→	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
←	outString	String&			Output string

Examples

→	←
inReal = 3.14159265359 **inIntegerDigitCount** = 2 **inFractionalDigitCount** = 3 **inDecimalMark** = "." **inTrailingCharacter** = "0" **inForceSignPrinting** = False **inSuffix** = "..."	**outString** = "03.142..."

In the example above desired integer digit count defined in **inIntegerDigitCount** equals 2, so the filter attaches trailing sign (zero) at the beginning of the result **outString**. Decimal mark (**inDecimalMark**) is set as a dot and the number of fractional digits (**inFractionalDigitCount**) as 3. The result string ends with ellipsis defined in **inSuffix** and the final result is "03.142...".
Note that the third digit was rounded up to "2" due to the succeeding digit.

→	←
inReal = 10.7 **inIntegerDigitCount** = 1 **inFractionalDigitCount** = 2 **inDecimalMark** = "," **inTrailingCharacter** = " " **inForceSignPrinting** = True **inSuffix** = " °C"	**outString** = "+10,70 °C"

This example demonstrates formatting of value 10.7 with one integer digit as defined in **inIntegerDigitCount** and two fractional digits described by **inFractionalDigitCount**. Note that the integer part of formatted number (**1**) is less than digits in integral part of passed value (**10**), but it doesn't affect to either (unlike the fractional part which can cuts off excessing digits).
Trailing character (**inTrailingCharacter**) doesn't affect to anything, because desired integer digit count is one (the same effect would be for zero).

Remarks

If you want to cut off excessing digits from a fractional part of a number (instead of rounding them), you can format a number with one extra precision digit and then use Substring to cut off the last digit.
You can add a suffix manually by using AvsFilter_ConcatenateStrings.

Errors

List of possible exceptions:

Error type	Description
DomainError	inDecimalMark has to be a single character in FormatRealToString.
DomainError	inTrailingCharacter has to be a single character in FormatRealToString.

LoadText

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Loads a text from a file.

Syntax

```
void avl::LoadText
(
 const atl::File& inFile,
 atl::String& outText
)
```

Parameters

	Name	Type	Default	Description
➡	inFile	const File&		
⬅	outText	String&		

Errors

List of possible exceptions:

Error type	Description
IoError	Source file is too large to be loaded as String in LoadText.

Also in AVL Lite

LoadTextLines

Header: STD.h
Namespace: avl
Module: FoundationLite

Loads text lines from a file.

Syntax

```
void avl::LoadTextLines
(
 const atl::File& inFile,
 const atl::String& inLineDelimiter,
 bool inSkipEmptyLines,
 atl::Array<atl::String>& outTextLines
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
→	inLineDelimiter	const String&	\"\\\\r\\\\n\"	End of line character sequence, escaped
→	inSkipEmptyLines	bool		
←	outTextLines	Array<String>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty LineDelimiter on input in LoadTextLines.

Also in AVL Lite

SaveText

Header: STD.h
Namespace: avl
Module: FoundationLite

Saves a text to a file.

Syntax

```
void avl::SaveText
(
 const atl::String& inText,
 avl::FileAccessMode::Type inFileAccessMode,
 const atl::File& inFile,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
→	inFileAccessMode	FileAccessMode::Type		
→	inFile	const File&		
→	inIgnoreErrors	bool		

SaveTextLines

Header: STD.h
Namespace: avl
Module: FoundationLite

Saves text lines to a file.

Syntax

```
void avl::SaveTextLines
(
 const atl::Array<atl::String>& inTextLines,
 avl::FileAccessMode::Type inFileAccessMode,
 const atl::File& inFile,
 const atl::String& inLineDelimiter,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Default	Description
➡	inTextLines	const Array<String>&		
➡	inFileAccessMode	FileAccessMode::Type		
➡	inFile	const File&		
➡	inLineDelimiter	const String&	\"\\\\r\\\\n\"	End of line character sequence, escaped
➡	inIgnoreErrors	bool		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty LineDelimiter on input in SaveTextLines.

8. Histogram Point Transforms

Table of content:

- AbsoluteHistogram
- AddToHistogram
- DivideHistogram
- MultiplyHistogram
- NegateHistogram
- SubtractFromHistogram

AbsoluteHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Transforms each bin value to its absolute value.

Syntax

```
void avl::AbsoluteHistogram
(
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
⬅	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

AddToHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Increases each bin value by a number.

Syntax

```
void avl::AddToHistogram
(
 const avl::Histogram& inHistogram,
 const double inValue,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
➡	inValue	const double	0.0D	Input value
⬅	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

DivideHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Divides each bin value by a number.

Syntax

```
void avl::DivideHistogram
(
 const avl::Histogram& inHistogram,
 const double inValue,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inValue	const double	2.0D	Input value
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Divisor is equal to zero on input in DivideHistogram.

MultiplyHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Multiplies each bin value by a number.

Syntax

```
void avl::MultiplyHistogram
(
 const avl::Histogram& inHistogram,
 const double inValue,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inValue	const double	2.0D	Input value
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

NegateHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Negates each bin value.

Syntax

```
void avl::NegateHistogram
(
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
⬅	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

SubtractFromHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Decreases each bin value by a number.

Syntax

```
void avl::SubtractFromHistogram
(
 const avl::Histogram& inHistogram,
 const double inValue,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
➡	inValue	const double	2.0D	Input value
⬅	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

9. Profile Point Transforms

Table of content:

- AbsoluteProfile
- AddToProfile
- ClipProfileValues
- DivideProfile
- MultiplyProfile
- NegateProfile
- NormalizeProfile
- RescaleProfile
- SubtractFromProfile

AbsoluteProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms each profile value to its absolute value.

Syntax

```
void avl::AbsoluteProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in AbsoluteProfile.

AddToProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Adds a scalar value to each element of a profile.

Syntax

```
void avl::AddToProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inValue	float		

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in AddToProfile.

PROFILE ClipProfileValues

Header: AVL.h
Namespace: avl
Module: FoundationPro

Applies limits to profile values.

Syntax

```
void avl::ClipProfileValues
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 const atl::Optional<float> inLowValue,
 const atl::Optional<float> inHighValue
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inLowValue	const Optional<float>	NIL	Value min threshold
	inHighValue	const Optional<float>	NIL	Value max threshold

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ClipProfileValues.
DomainError	Value of inHighValue is less than inLowValue in ClipProfileValues.

PROFILE DivideProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Divides each element of a profile by a scalar value.

Syntax

```
void avl::DivideProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inValue	float	2.0f	

Errors

List of possible exceptions:

Error type	Description
DomainError	Divisor is equal to zero on input in DivideProfile.
DomainError	Range exceeds the input profile in DivideProfile.

PROFILE MultiplyProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Multiplies each element of a profile by a scalar value.

Syntax

```
void avl::MultiplyProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inValue	float	2.0f	

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in MultiplyProfile.

PROFILE NegateProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms each profile value to its negation.

Syntax

```
void avl::NegateProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in NegateProfile.

NormalizeProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Rescales a profile linearly, so that its minimum becomes inNewMinimum and its maximum becomes inNewMaximum.

Syntax

```
void avl::NormalizeProfile
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 atl::Optional<float> inNewMinimum,
 atl::Optional<float> inNewMaximum,
 const float inSaturateHighestFraction,
 const float inSaturateLowestFraction,
 avl::Profile& outProfile,
 float& outA,
 float& outB
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inNewMinimum	Optional<float>		NIL	Desired minimum value of the resulting profile (if set to Nil, the minimum of the input profile is used)
→	inNewMaximum	Optional<float>		NIL	Desired maximum value of the resulting profile (if set to Nil, the maximum of the input profile is used)
→	inSaturateHighestFraction	const float	0.0 – 1.0	0.0f	Fraction of the highest values skipped during normalization
→	inSaturateLowestFraction	const float	0.0 – 1.0	0.0f	Fraction of the lowest values skipped during normalization
←	outProfile	Profile&			Normalized profile
←	outA	float&			Multiplicative parameter of the applied linear transformation
←	outB	float&			Additive parameter of the applied linear transformation

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds inProfile in NormalizeProfile.
DomainError	The sum of inSaturateHighestFraction and inSaturateLowestFraction can't be greater than 1 in NormalizeProfile.

RescaleProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Applies a linear transformation to a profile.

Syntax

```
void avl::RescaleProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 float inA,
 float inB
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inA	float	1.0f	Value multiplied
	inB	float	0.0f	Value added

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in RescaleProfile.

SubtractFromProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Subtracts a scalar value from each element of a profile.

Syntax

```
void avl::SubtractFromProfile
(
 avl::Profile& ioProfile,
 atl::Optional<const avl::Range&> inRange,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioProfile	Profile&		
	inRange	Optional<const Range&>	NIL	
	inValue	float		

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in SubtractFromProfile.

AbsoluteSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Transforms Z coordinate of each surface point to its absolute value.

Syntax

```
void avl::AbsoluteSurface
(
 const avl::Surface& inSurface,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outSurface	Surface&		Output surface

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

CloseSurfacePoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Reconstructs missing points of the input surface by interpolating neighboring points.

Syntax

```
void avl::CloseSurfacePoints
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outSurface	Surface&			Output surface

Description

The operation reconstructs some of missing points of the input surface by interpolating their neighboring points. Internally the region of surface valid points is closed using defined kernel. Every missing point in location that have emerged because of the closing is substituted with the arithmetic mean of existing points in locations that would be covered by the kernel if the middle of the kernel was precisely over the missing point location.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in CloseSurfacePoints.

See Also

- SurfaceValidPointsRegion – Computes region of locations where points are valid in a surface and where they are invalid.
- CloseRegion – Performs a morphological closing on a region using selected predefined kernel.

CropSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are not contained in a given rectangular box.

Syntax

```
void avl::CropSurface
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::ValueLimits_f64& inXLimits,
 const avl::ValueLimits_f64& inYLimits,
 const avl::ValueLimits_f64& inZLimits,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inXLimits	const ValueLimits_f64&		
→	inYLimits	const ValueLimits_f64&		
→	inZLimits	const ValueLimits_f64&		
→	inPreserveDimensions	bool	False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&		Output surface
←	outRejected	Optional<Region&>	NIL	Region of locations where points are not contained in a given rectangular box

Optional Outputs

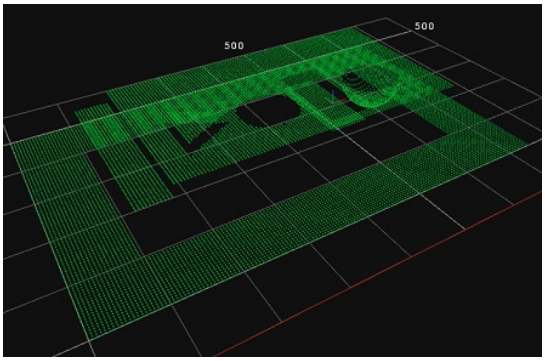
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

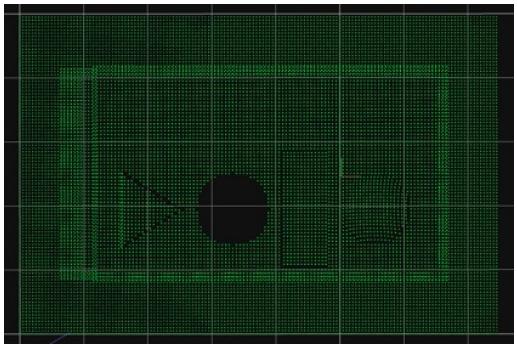
Description

The operation removes points from surface that are not contained in a given rectangular box within provided coordinates.
It is also possible to narrow this box by editing **inRoi**, Region of Interest of operation.
Coordinates are defined via acceptable limits for their values. E.g. **inXLimits.MinValue** is minimum and **inXLimits.MaxValue** is maximum value of the X coordinate. Every point with its X coordinate outside of this range is removed.
Flag **inPreserveDimensions** informs if the operation output should keep the original dimensions of its input. E.g. if **inSurface** has its Width=300, Height=200 and Pitch=608 and the flag is enabled, the **outSurface** will have exactly the same dimensions of 300x200x608. However, if the flag is disabled, **outSurface** will have its dimensions smaller to adjust them to surface size, but its XOffset, YOffset, ZOffset properties will be accordingly bigger in order to keep the surface in the same place in workspace.
Operation returns the cropped Surface as well as removed Region if one needs to perform further actions on removed points.

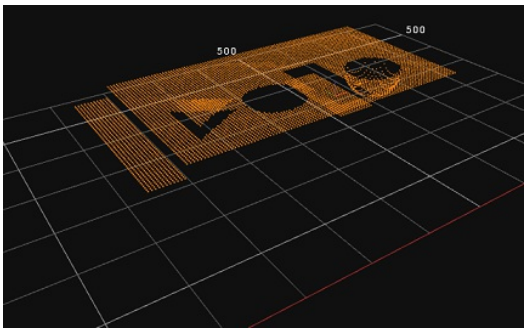
Examples



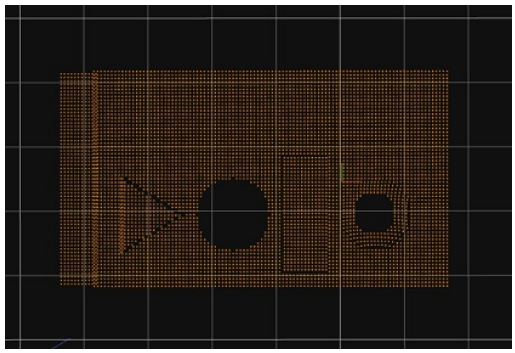
A sample Surface object.



The same Surface object seen from above.



A sample Surface object cropped through half of its height.



Cropped Surface object seen from above.

Name	Type	Value
⊟ (2)CropSurface		
⊟ outSurface	Surface	{...}
Width	Integer	150
Height	Integer	100
Pitch	Integer	304
Type	PlainType	Int16
PointByteSize	Integer	2
XOffset	Double	0,000
XScale	Double	5,000
YOffset	Double	0,000
YScale	Double	5,000
ZOffset	Double	0,000
ZScale	Double	1,000

Properties of a cropped surface with dimension preservation enabled.

Name	Type	Value
⊟ (3)CropSurface		
⊟ outSurface	Surface	{...}
Width	Integer	111
Height	Integer	61
Pitch	Integer	224
Type	PlainType	Int16
PointByteSize	Integer	2
XOffset	Double	100,000
XScale	Double	5,000
YOffset	Double	100,000
YScale	Double	5,000
ZOffset	Double	0,000
ZScale	Double	1,000

Properties of a cropped surface with dimension preservation disabled.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in CropSurface.

See Also

- CropSurfaceToRegion – Removes points that are not present in a given region.

- Point3DGrid

CropSurfaceByNeighborsProximity

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are too distant from their neighbor points.

Syntax

```
void avl::CropSurfaceByNeighborsProximity
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const int inNeighborRadius,
 const float inMaxDistance,
 avl::Metric3D::Type inMetric,
 const float inMinNeighborRatio,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inNeighborRadius	const int	1 – ∞	1	Radius of neighbors to search for real neighbors
→	inMaxDistance	const float	0.0 – ∞	2.0f	Maximal distance from another point to consider them real neighbors
→	inMetric	Metric3D::Type		Z	Metric used for measuring distance between points
→	inMinNeighborRatio	const float	0.0 – 1.0	1.0f	Fraction of valid neighbors in a given radius that have to be real neighbors
→	inPreserveDimensions	bool		False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&			
←	outRejected	Optional<Region&>		NIL	Region of locations where points are too distant from their neighbors

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect metric in CropSurfaceByNeighborsProximity.
DomainError	Region of interest exceeds an input surface in CropSurfaceByNeighborsProximity.

CropSurfaceByPlaneProximity

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are too distant from a given plane.

Syntax

```
void avl::CropSurfaceByPlaneProximity
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Plane3D& inPlane,
 atl::Optional<float> inMinDistance,
 atl::Optional<float> inMaxDistance,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inPlane	const Plane3D&		Plane to which distance is measured
→	inMinDistance	Optional<float>	NIL	Minimal distance from a given plane
→	inMaxDistance	Optional<float>	1.0f	Maximal distance from a given plane
→	inPreserveDimensions	bool	False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&		Output surface
←	outRejected	Optional<Region&>	NIL	Region of locations where points are too distant from the input plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in CropSurfaceByPlaneProximity.
DomainError	Region of interest exceeds an input surface in CropSurfaceByPlaneProximity.

CropSurfaceToBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are not contained in a given box in 3D.

Syntax

```
void avl::CropSurfaceToBox3D
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Box3D& inBox3D,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inBox3D	const Box3D&		Box defining a subspace to be cropped
→	inPreserveDimensions	bool	False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&		Output surface
←	outRejected	Optional<Region&>	NIL	Region of locations where points are not contained in a given box in 3D

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in CropSurfaceToBox3D.

CropSurfaceToRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes points that are not present in a given region.

Syntax

```
void avl::CropSurfaceToRegion
(
 const avl::Surface& inSurface,
 const avl::Region& inRegion,
 bool inPreserveDimensions,
 avl::Surface& outSurface
)
```

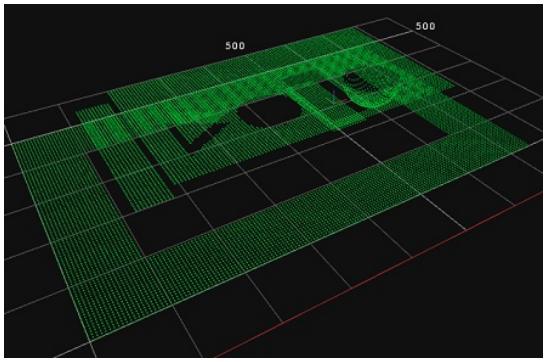
Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRegion	const Region&		Region from which the points are not removed
→	inPreserveDimensions	bool	False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&		Output surface

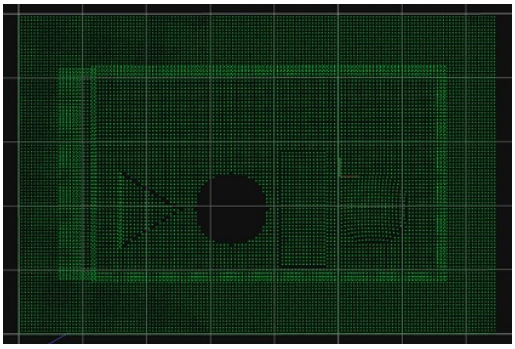
Description

The operation removes points from surface that are not contained in a given rectangular box within provided Region.
This operation is very similar to CropSurface, although it is slightly limited. Region within the surface will be cropped is viewed from above. This means that it is possible to edit the input within a two-dimensional space through the X and Y axis instead of X, Y and Z axis in CropSurface filter.
Flag **inPreserveDimensions** informs if the operation output should keep the original dimensions of its input. E.g. if **inSurface** has its Width=300, Height=200 and Pitch=608 and the flag is enabled, the **outSurface** will have exactly the same dimensions of 300x200x608. However, if the flag is disabled, **outSurface** will have its dimensions smaller to adjust them to surface size, but its XOffset, YOffset, ZOffset properties will be accordingly bigger in order to keep the surface in the same place in workspace.

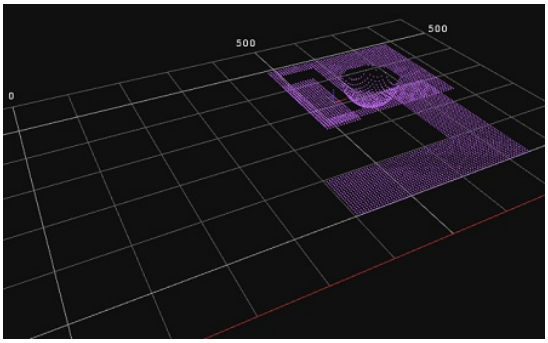
Examples



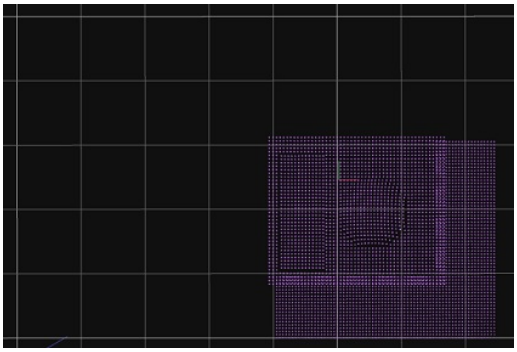
A sample Surface object.



The same Surface object seen from above.



A sample Surface object cropped within the Region of a bottom-right part of surface.



Cropped Surface object seen from above.

Name	Type	Value
⊟ (5)CropSurfaceToRegion		
⊟ outSurface	Surface	{...}
Width	Integer	150
Height	Integer	100
Pitch	Integer	304
Type	PlainType	Int16
PointByteSize	Integer	2
XOffset	Double	0,000
XScale	Double	5,000
YOffset	Double	0,000
YScale	Double	5,000
ZOffset	Double	0,000
ZScale	Double	1,000

Properties of a cropped surface with dimension preservation enabled.

Name	Type	Value
⊟ (4)CropSurfaceToRegion		
⊟ outSurface	Surface	{...}
Width	Integer	69
Height	Integer	62
Pitch	Integer	144
Type	PlainType	Int16
PointByteSize	Integer	2
XOffset	Double	405,000
XScale	Double	5,000
YOffset	Double	0,000
YScale	Double	5,000
ZOffset	Double	0,000
ZScale	Double	1,000

Properties of a cropped surface with dimension preservation disabled.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input region exceeds surface dimensions in CropSurfaceToRegion.

See Also

- CropSurface – Removes from the surface points that are not contained in a given rectangular box.
- TestSurface – Returns a sample 3D surface.
- Point3DGrid

CropSurface_Dynamic

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are relatively too distant from their average neighbor points in a local rectangular neighborhood.

Syntax

```
void avl::CropSurface_Dynamic
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 atl::Optional<float> inMinRelativeHeight,
 atl::Optional<float> inMaxRelativeHeight,
 float inHysteresis,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL,
 avl::Surface& diagBaseSurface = atl::Dummy<avl::Surface>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inRadiusX	int	0 – ∞	1	Horizontal radius of internal mean blur
→	inRadiusY	Optional<int>	0 – ∞	NIL	Vertical radius of internal mean blur (Auto = inRadiusX)
→	inMinRelativeHeight	Optional<float>		NIL	Minimum relative height of a point to be not removed
→	inMaxRelativeHeight	Optional<float>		NIL	Maximum relative height of a point to be not removed
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for points neighboring with other not removed points
→	inPreserveDimensions	bool		False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&			
←	outRejected	Optional<Region&>		NIL	Region of locations where points are removed
🔍	diagBaseSurface	Surface&			Diagnostic blurred input surface

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in CropSurface_Dynamic.

CropSurface_Relative

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes from the surface points that are relatively too distant from their average neighbor points in a local rectangular neighborhood.

Syntax

```
void avl::CropSurface_Relative
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Surface& inBaseSurface,
 atl::Optional<float> inMinRelativeHeight,
 atl::Optional<float> inMaxRelativeHeight,
 float inHysteresis,
 bool inPreserveDimensions,
 avl::Surface& outSurface,
 atl::Optional<avl::Region&> outRejected = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inBaseSurface	const Surface&			Heights of this surface are subtracted from inSurface heights before crop
→	inMinRelativeHeight	Optional<float>		NIL	Minimum relative height of a point to be not removed
→	inMaxRelativeHeight	Optional<float>		NIL	Maximum relative height of a point to be not removed
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for points neighboring with other not removed points
→	inPreserveDimensions	bool		False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&			
←	outRejected	Optional<Region&>		NIL	Region of locations where points are removed

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRejected**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in CropSurface_Relative.
DomainError	Surface formats are not the same in CropSurface_Relative.
DomainError	Surface sizes are not equal in CropSurface_Relative.

DilateSurfacePoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Reconstructs missing points of the input surface by interpolating neighboring points.

Syntax

```
void avl::DilateSurfacePoints
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outSurface	Surface&			Output surface

Description

The operation reconstructs some of missing points of the input surface by interpolating their neighboring points. Internally the region of surface valid points is dilated using defined kernel. Every missing point in location that have emerged because of the dilation is substituted with the arithmetic mean of existing points in locations that would be covered by the kernel if the middle of the kernel was precisely over the missing point location.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in DilateSurfacePoints.

See Also

- SurfaceValidPointsRegion – Computes region of locations where points are valid in a surface and where they are invalid.
- DilateRegion – Performs a morphological dilation on a region using a predefined kernel.

ErodeSurfacePoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes some existing points from the input surface when some points in their vicinity are missing.

Syntax

```
void avl::ErodeSurfacePoints
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 bool inPreserveDimensions,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
→	inPreserveDimensions	bool			Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&			Output surface

Description

The operation removes some existing points from the input surface when some points in their vicinity are missing. Internally the region of surface valid points is eroded using defined kernel. The surface points in locations that have vanished because of the erosion are removed and substituted with indefinite points.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in ErodeSurfacePoints.

See Also

- SurfaceValidPointsRegion – Computes region of locations where points are valid in a surface and where they are invalid.
- ErodeRegion – Performs a morphological erosion on a region using a predefined kernel.

FlattenSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Flattens a curved surface.

Syntax

```
void avl::FlattenSurface
(
 const avl::Surface& inSurface,
 const avl::Axis::Type inCurvatureAxis,
 const float inStdDev,
 avl::Surface& outSurface,
 avl::Surface& diagSmoothedSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inCurvatureAxis	const Axis::Type			Axis along which the input surface is curved
→	inStdDev	const float	0.0 – ∞		Standard deviation for smoothing of the surface
←	outSurface	Surface&			Output surface
🔍	diagSmoothedSurface	Surface&			Surface smoothed with a Gaussian kernel

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown axis type in FlattenSurface.

FlattenSurface_WithScalePreserving

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Flattens a curved surface preserving the scale on the axes.

Syntax

```
void avl::FlattenSurface_WithScalePreserving
(
 const avl::Surface& inSurface,
 const avl::Axis::Type inCurvatureAxis,
 const float inStdDev,
 avl::Point3DGrid& outFlattenedGrid,
 avl::Surface& diagSmoothedSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inCurvatureAxis	const Axis::Type			Axis along which the input surface is curved
→	inStdDev	const float	0.0 – ∞		Standard deviation for smoothing of the surface
←	outFlattenedGrid	Point3DGrid&			Output point grid
🔍	diagSmoothedSurface	Surface&			Surface smoothed with a Gaussian kernel

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown axis type in FlattenSurface_WithScalePreserving.

JoinSurfaces

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Combines two surfaces into one.

Syntax

```
void avl::JoinSurfaces
(
 const avl::Surface& inSurface1,
 const avl::Surface& inSurface2,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface1	const Surface&		First input surface to join
→	inSurface2	const Surface&		Second input surface to join
←	outSurface	Surface&		Combination of two input surfaces

Remarks

The joined surfaces must be compatible. Their scales must be equal and the difference between the corresponding offsets must be equal to the multiple of the related scale.

The filter will return the mean of the points where the surfaces overlap each other.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different axis scales in JoinSurfaces.
DomainError	Different Surface types in JoinSurfaces.
DomainError	Incompatible axis offsets in JoinSurfaces.

MirrorSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Transforms Z coordinate of each surface point to its opposite value.

Syntax

```
void avl::MirrorSurface
(
 const avl::Surface& inSurface,
 avl::Surface& outSurface,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outSurface	Surface&		Mirrored surface
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to mirror the surface

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

OpenSurfacePoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Removes some existing points from the input surface when some points in their vicinity are missing.

Syntax

```
void avl::OpenSurfacePoints
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 bool inPreserveDimensions,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
→	inPreserveDimensions	bool			Flag indicating whether the surface dimensions should be preserved or not
←	outSurface	Surface&			Output surface

Description

The operation removes some existing points from the input surface when some points in their vicinity are missing. Internally the region of surface valid points is opened using defined kernel. The surface points in locations that have vanished because of the opening are removed and substituted with indefinite points.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in OpenSurfacePoints.

See Also

- SurfaceValidPointsRegion – Computes region of locations where points are valid in a surface and where they are invalid.
- OpenRegion – Performs a morphological opening on a region using a predefined kernel.

ProjectSurfaceOntoPlane

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Projects a surface on another plane, replacing Z coordinate of a point with its distance from a given plane.

Syntax

```
void avl::ProjectSurfaceOntoPlane
(
 const avl::Surface& inSurface,
 const avl::Plane3D& inPlane,
 const bool inUseAbsoluteDistance,
 const bool inPreserveOffsetsAndScales,
 avl::Surface& outSurface,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		
→	inPlane	const Plane3D&		
→	inUseAbsoluteDistance	const bool		
→	inPreserveOffsetsAndScales	const bool	True	Flag indicating whether to preserve input surface offsets and scales or to adjust them accordingly
←	outSurface	Surface&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to compute the output surface; signed distance usage is assumed

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in ProjectSurfaceOntoPlane.

ReduceSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Reduces surface dimensions as much as possible.

Syntax

```
void avl::ReduceSurface
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outSurface	Surface&		Reduced surface

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in ReduceSurface.

RescaleSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Changes the distances of surface points to a reference point.

Syntax

```
void avl::RescaleSurface
(
 const avl::Surface& inSurface,
 const avl::Point3D& inReferencePoint,
 float inScaleX,
 atl::Optional<float> inScaleY,
 atl::Optional<float> inScaleZ,
 bool inInverse,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inReferencePoint	const Point3D&		Point to which the distances will be changed
→	inScaleX	float	1.0f	Scaling factor along X axis
→	inScaleY	Optional<float>	NIL	Scaling factor along Y axis
→	inScaleZ	Optional<float>	NIL	Scaling factor along Z axis
→	inInverse	bool		Switches to the inverse operation
←	outSurface	Surface&		Rescaled surface

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling in RescaleSurface.

SplitSurfaceByPlane

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Separates the surface points being on one side of the input plane from the others.

Syntax

```
void avl::SplitSurfaceByPlane
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Plane3D& inPlane,
 bool inPreserveDimensions,
 avl::Surface& outSurface1,
 avl::Surface& outSurface2
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inPlane	const Plane3D&		Plane used for splitting
→	inPreserveDimensions	bool	False	Flag indicating whether the surface dimensions should be preserved or not
←	outSurface1	Surface&		Surface with points with positive signed distance to the input plane
←	outSurface2	Surface&		Surface with points with negative signed distance to the input plane

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SplitSurfaceByPlane.
DomainError	Region of interest exceeds an input surface in SplitSurfaceByPlane.

SubtractSurfaces

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Subtracts two surfaces point by point.

Syntax

```
void avl::SubtractSurfaces
(
 const avl::Surface& inSurface1,
 const avl::Surface& inSurface2,
 atl::Optional<const avl::Region&> inRoi,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface1	const Surface&		First input surface
→	inSurface2	const Surface&		Second input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outSurface	Surface&		Output surface

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different surface dimensions in SubtractSurfaces.
DomainError	Different surface scales or offsets in SubtractSurfaces.
DomainError	Different surface types in SubtractSurfaces.
DomainError	Region of interest exceeds an input surface in SubtractSurfaces.

TranslateSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Translates a surface by a vector.

Syntax

```
void avl::TranslateSurface
(
 const avl::Surface& inSurface,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outSurface	Surface&		Translated surface

AbsoluteValueImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms pixel values to their absolute values pixel by pixel.

Syntax

```
void avl::AbsoluteValueImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AbsoluteValueImage.

AddNoiseToImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds random noise to the image.

Syntax

```
void avl::AddNoiseToImage
(
 RandomState& ioState,
 const avl::Image& inImage,
 const float inMinValue,
 const float inMaxValue,
 const float inNoiseStrength,
 const bool inColorNoise,
 atl::Optional<int> inSeed,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	RandomState&			Object used to maintain state of the function.
	inImage	const Image&			Input image
	inMinValue	const float		0.0f	Minimum value of noise pixel, inclusive
	inMaxValue	const float		256.0f	Maximum value of noise pixel, exclusive
	inNoiseStrength	const float	0.0 – 1.0	0.5f	Noise strength
	inColorNoise	const bool			If 'True', noise will be generated separately for each channel
	inSeed	Optional<int>		NIL	Random seed used to generate noise
	outImage	Image&			Output image

AddToImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds a scalar value to each pixel.

Syntax

```
void avl::AddToImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	inImage	const Image&		Input image
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	inValue	float	50.0f	Value to be added
	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

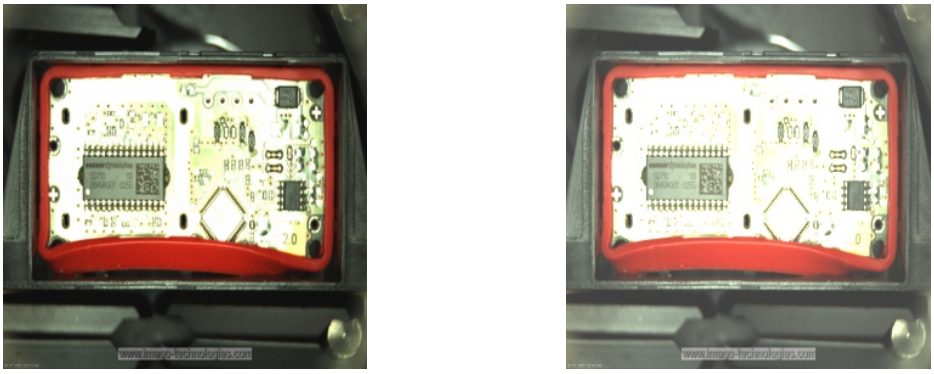
Description

The operation increases the brightness of the **inImage** by adding a fixed value to each of its pixels.

$$\forall_{i,j} \mathbf{OutImage}_{i,j} = \mathbf{InImage}_{i,j} + \mathbf{inValue}$$

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value.

Examples



*The **AddToImage** performed on the sample image with **inValue** = 50.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AddToImage.

See Also

- SubtractFromImage – Subtracts a scalar value from each pixel.

ClipPixels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets pixels below the low value to the low value and above the high value to the high value.

Syntax

```
void avl::ClipPixels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<float> inLowValue,
 atl::Optional<float> inHighValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inLowValue	Optional<float>	64.0f	The lower threshold for the image pixel values
→	inHighValue	Optional<float>	192.0f	The higher threshold for the image pixel values
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ClipPixels.
DomainError	The low value cannot be higher than the high value in ClipPixels.

Also in AVL Lite

ColorizeImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shows a monochromatic image in false colors.

Syntax

```
void avl::ColorizeImage
(
 ColorizeImageState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::ColorPalette::Type inPalette,
 bool inNegate,
 atl::Optional<int> inMinValue,
 atl::Optional<int> inMaxValue,
 avl::Image& outImage,
 avl::Image& diagPalette
)
```

Parameters

	Name	Type	Default	Description
	ioState	ColorizeImageState&		Object used to maintain state of the function.
	inImage	const Image&		Input image
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	inPalette	ColorPalette::Type	Iron	Palette of colors which is used to replace pixels
	inNegate	bool		Reversing palette colors
	inMinValue	Optional<int>	0	Minimal value of pixel that will be replaced by color from palette, otherwise first color from palette will be set
	inMaxValue	Optional<int>	255	Maximal value of pixel that will be replaced by color from palette, otherwise last color from palette will be set
	outImage	Image&		Output image
	diagPalette	Image&		Used palette preview

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×uint16.

Read more about pixel formats in Image documentation.

Description

This filter is especially useful for visualization purposes. For example, the **Iron** palette is prepared for showing infrared images in thermo-graphic appliances.

Parameters **inMinValue** and **inMaxValue** defines the scale that should be applied to image pixels. Pixels outside this range are reduced to minimal or maximal value in range.

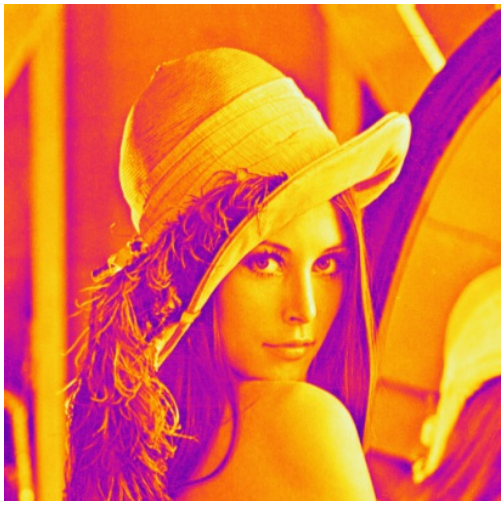
If parameters **inMinValue** or **inMaxValue** is set to **Auto** the filter will find the maximal or minimal pixel value.

This filter works only with single channel images.

Hints

- Consider resizing image to smaller format if image does not require to contain details.
- This filter can be used to show differences between object and background noises.

Examples



*The ColorizeImage performed on the result of TestImage with **inPalette** set to **Iron**.*

Remarks

Filter pre-computes after changing its parameter which can affect the filter's execution speed. Try to avoid changing filter's parameter during program execution.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inMinValue is greater than inMaxValue in ColorizeImage.
DomainError	Input image must have 1xUInt8 or 1xUInt16 format in ColorizeImage.
DomainError	Region exceeds an input image in ColorizeImage.
DomainError	Not supported inImage pixel format in ColorizeImage. Supported formats: 1xUInt8, 1xUInt16.

See Also

- LUTTransformImage – Changes pixel values for data stored in array.

CorrectGamma

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs gamma correction.

Applications: Image enhancement for human perception. For computer vision consider LogarithmImage.

Syntax

```
void avl::CorrectGamma
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inValue	float	0.01 – 8.0	2.0f	Gamma coefficient, where 1.0 is neutral
←	outImage	Image&			Output image

Requirements

For input **inImage** only pixel formats are supported: int8, uint8, int16, uint16, int32.

Read more about pixel formats in Image documentation.

In-place Processing

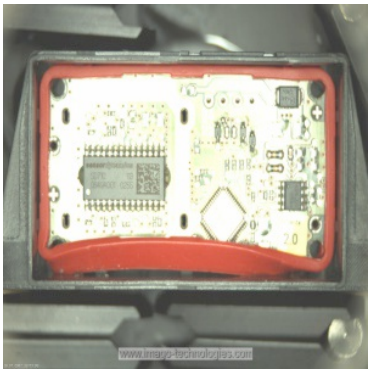
This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The gamma correction is a standard nonlinear transformation of pixel brightness that was developed as a tool for the compensation of CRT display input-output characteristic. The operation scales brightness of each **inImage** pixel to the 0.0 – 1.0 range, exponentiates it to the power of **inValue**, and then scales the result back to the pixel values range.

Examples



*The **CorrectGamma** performed on the sample image with **inValue** = 2.0 (left image) and **inValue** = 0.5 (right image).*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in CorrectGamma. Supported formats: Int8, UInt8, Int16, UInt16, Int32.

See Also

- RescalePixels – Applies linear transformation to pixel values.

Also in **AVL Lite**

DivideImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Divides each pixel by a scalar value.

Syntax

```
void avl::DivideImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inValue	float	2.0f	Divisor
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

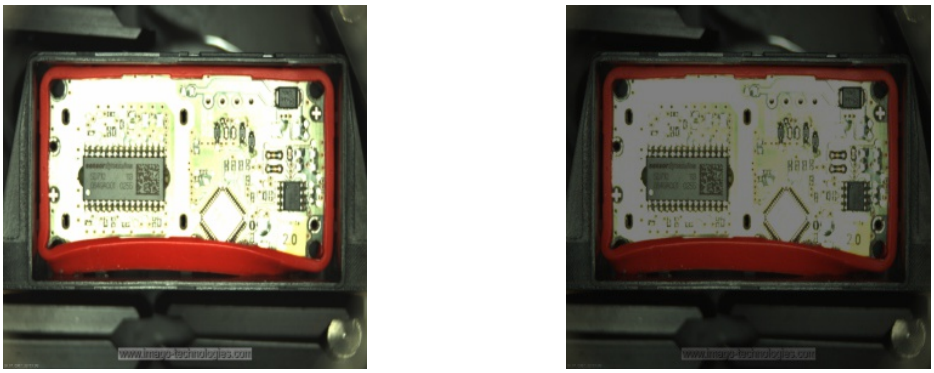
Description

The operation decreases the brightness of the **inImage** dividing each of its pixels by a fixed value.

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \frac{\mathrm{InImage}_{i,j}}{\mathrm{inValue}}$$

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value.

Examples



DivideImage *performed on the sample image with* ***inValue*** *= 2.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Division by zero in DivideImage.
DomainError	Region exceeds an input image in DivideImage.

See Also

- MultiplyImage - Multiplies each pixel by a scalar value.

InvertImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Applies numeric inversion (1/x) of the pixel values.

Syntax

```
void avl::InvertImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inDividend,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inDividend	float		
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in InvertImage.

LogarithmImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a natural logarithm of each pixel.

Applications: Transforms an image in such a way that a quotient on the input image becomes a difference on the output image. This can be useful for dealing with variable illumination.

Syntax

```
void avl::LogarithmImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const float&> inScale,
 float inOffset,
 bool inNormalizeZero,
 avl::Image& outImage,
 avl::Profile& diagLutProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inScale	Optional<const float&>		NIL	Scaling factor (default: 255)
→	inOffset	float	$1.0 - \infty$	1.0f	Offset factor
→	inNormalizeZero	bool			Specifies whether the output range should be rescaled to start from 0
←	outImage	Image&			Output image
🔍	diagLutProfile	Profile&			Profile depicting the resulting look-up table of the logarithm transform

Requirements

For input **inImage** only pixel formats are supported: int8, uint8, int16, uint16, int32.

Read more about pixel formats in Image documentation.

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The operation applies logarithmic operator to each pixel of an image. Logarithmic operator is defined as follows:

$$inScale \cdot \frac{log(inOffset + |P(x,y)|)}{log(inOffset + M)}$$

where:

- **M** is the maximum of the **inImage** type (i.e. 255 for UInt8, 127 for Int8).
- **inScale** is the expected maximum value of the transformation. If set to *Auto* it will result in value 127 for Int8 image and 255 for other image types.
- **inOffset** value corresponds to the camera's black level. Its default value is equal 1 and causes the strongest possible transform.

When **inNormalizeZero** is set to **True**, the result is not only scaled, but also normalized so that pixel value 0 is still transformed into value 0. This assures that the entire output value range is utilized.

Examples

*The **LogarithmImage** performed on the sample image with parameters **inScale** = 250, **inOffset** = 50. The middle image **inNormalizeZero** = **False** and the left image has **inNormalizeZero** = **True**.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in LogarithmImage. Supported formats: Int8, UInt8, Int16, UInt16, Int32.

LUTTransformImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes pixel values for data stored in array.

Syntax

```
void avl::LUTTransformImage
(
 LUTTransformImageState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const atl::Array<int>& inColorPoints,
 const atl::Array<avl::Pixel>& inColors,
 const bool inComputeGradient,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	LUTTransformImageState&		Object used to maintain state of the function.
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inColorPoints	const Array<int>&		Last pixel value in which corresponding color will be replaced.
→	inColors	const Array<Pixel>&		Colors corresponding to pixel levels defined in inColorPoints.
→	inComputeGradient	const bool		Compute the linear change of pixels colors between next palette colors.
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×uint16, 1×int8, 1×int16.

Read more about pixel formats in Image documentation.

Description

Filter applies pixel color transformation using the defined transformation colors (look-up table).

Input **inColorPoints** defines the maximal pixel values that should be replaced with colors defined in **inColors**. First color replace all pixels from 0 to **inColorPoints**[0], second color will replace all colors from **inColors**[1]+1 to **inColors**[2] and so on. All pixel values higher than last **inColorPoints** will be replaced with black pixel.

If the input **inComputeGradient** is set to **True** then the pixel value is computed as a linear interpolation between current and previous color defined in **inColors**. For the first color in **inColors** the previous color is set to minimal value of current pixel format.

Filter converts a single channel image to three RGB channels image.

This filter works only with single channel images.

Hints

- Consider resizing image to smaller format if image does not require to contain details.
- This filter can be used to show differences between object and background noises.

Examples

*The **LUTTransformImage** applied to a result of TestImage. In the middle image the **inComputeGradient** is set to **False** in the left image the **inComputeGradient** is set to **True**.*

Remarks

Filter pre-computes after changing its parameter which can affect the filter's execution speed. Try to avoid changing filter's parameter during program execution.

If no color values are provided in **inColorPoints** filter returns an empty image.

If a single color value is provided in **inColorPoints** filter returns an image filled with this color.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inColorPoints and InColors has different sizes LUTTransformImage.
DomainError	inColorPoints must be sorted in raising order in LUTTransformImage.
DomainError	Input image must have 1xUInt8, 1xUInt16, 1xInt8 or 1xInt16 format in LUTTransformImage.
DomainError	Region exceeds an input image in LUTTransformImage.
DomainError	Not supported inImage pixel format in LUTTransformImage. Supported formats: 1xUInt8, 1xUInt16, 1xInt8, 1xInt16.

See Also

- ColorizeImage – Shows a monochromatic image in false colors.

MultiplyImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Multiplies each pixel by a scalar value.

Syntax

```
void avl::MultiplyImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inValue	float	2.0f	Multiplier
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

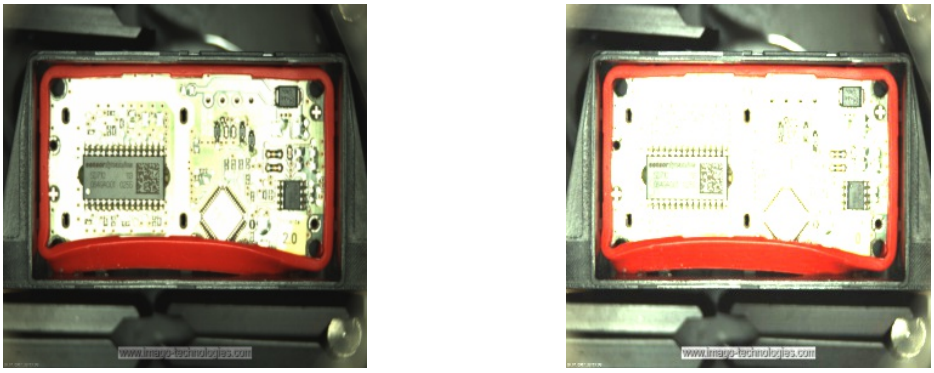
Description

The operation increases the brightness of an image by multiplying each of its pixels by a fixed value.

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \mathrm{InImage}_{i,j} \cdot \mathrm{inValue}$$

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value.

Examples



*The **MultiplyImage** performed on the sample image with **inValue** = 2.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in MultiplyImage.

See Also

- DivideImage – Divides each pixel by a scalar value.

NegateImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reverts the pixel value range (unsigned) or applies numeric negation (signed).

Syntax

```
void avl::NegateImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The operation negates the pixel values of the **inImage**. Depending on the pixel type, the negation is defines as follows:

- For the signed pixel types: $\forall_{i,j} \mathrm{OutImage}_{i,j} = -\mathrm{InImage}_{i,j}$
- For the unsigned pixel types: $\forall_{i,j} \mathrm{OutImage}_{i,j} = \mathrm{MaximalValue} - \mathrm{InImage}_{i,j}$ (which can be thought of as *mirroring* the pixel values around the center of the pixel values range)

Examples

*The **NegateImage** performed on the sample image.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL NEON: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in NegateImage.

PowerImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Exponentiates each pixel to the given power.

Syntax

```
void avl::PowerImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inValue	float	2.0f	The exponent
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Remarks

When diagnostic mode is used, this filter will check correctness of input data and throw an exception if possibility of NaN value in output image occur. When working in optimized mode, this check is omitted.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- CorrectGamma - Performs gamma correction.
- LogarithmImage - Computes a natural logarithm of each pixel.

ReplacePixels

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Substitutes pixels having the specified value with a new value.

Syntax

```
void avl::ReplacePixels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Pixel& inOldPixel,
 const avl::Pixel& inNewPixel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inOldPixel	const Pixel&		
→	inNewPixel	const Pixel&		
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 1xSINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ReplacePixels.

ResaturateImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets pixels below the low value to minimum, above the high value to maximum, and interpolates the rest.

Syntax

```
void avl::ResaturateImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inLowValue,
 float inHighValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inLowValue	float	64.0f	The value that will be changed to minimum (usually 0)
→	inHighValue	float	192.0f	The value that will be changed to maximum (usually 255)
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: int8, uint8, int16, uint16, int32.

Read more about pixel formats in Image documentation.

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ResaturateImage.
DomainError	Not supported inImage pixel format in ResaturateImage. Supported formats: Int8, UInt8, Int16, UInt16, Int32.

See Also

- NormalizeImage - Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.
- AddToImage - Adds a scalar value to each pixel.
- RescalePixels - Applies linear transformation to pixel values.

RescalePixels

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Applies linear transformation to pixel values.

Syntax

```
void avl::RescalePixels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inA,
 float inB,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inA	float	1.0f	Value multiplied
→	inB	float	0.0f	Value added
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The operation applies linear transformation to pixel values.

$$\forall_{i,j} outImage_{i,j} = inA \cdot inImage_{i,j} + inB$$

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in RescalePixels.

See Also

- ResaturateImage - Sets pixels below the low value to minimum, above the high value to maximum, and interpolates the rest.
- AddToImage - Adds a scalar value to each pixel.
- NormalizeImage - Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.

RescalePixels_FixedRange

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms pixels value from given range into new one.

Syntax

```
void avl::RescalePixels_FixedRange
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inMinValue,
 float inMaxValue,
 float inNewMinValue,
 float inNewMaxValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inMinValue	float		Declared minimum value of input image
→	inMaxValue	float		Declared maximum value of input image
→	inNewMinValue	float		Desired minimum value of the resulting image
→	inNewMaxValue	float		Desired maximum value of the resulting image
←	outImage	Image&		Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	A inMinValue cannot be equal to inMaxValue in RescalePixels_FixedRange.
DomainError	A inMinValue cannot be higher than the inMaxValue in RescalePixels_FixedRange.
DomainError	The inNewMinValue cannot be higher than the inNewMaxValue in RescalePixels_FixedRange.

SquareImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Raises pixel values to the second power pixel by pixel.

Syntax

```
void avl::SquareImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

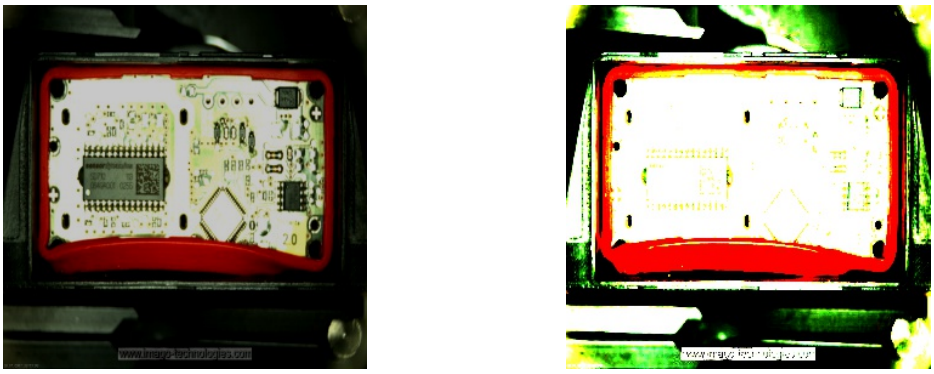
This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The operation increases the brightness of an image by squaring each pixel value. Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. Note that the absolute change of pixel brightness is usually very big.

Examples



*The **SquareImage** performed on the sample image.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SquareImage.

See Also

- SquareRootImage - Transforms pixel values to their square roots pixel by pixel.

SquareRootImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms pixel values to their square roots pixel by pixel.

Syntax

```
void avl::SquareRootImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: uint8, uint16.

Read more about pixel formats in Image documentation.

In-place Processing

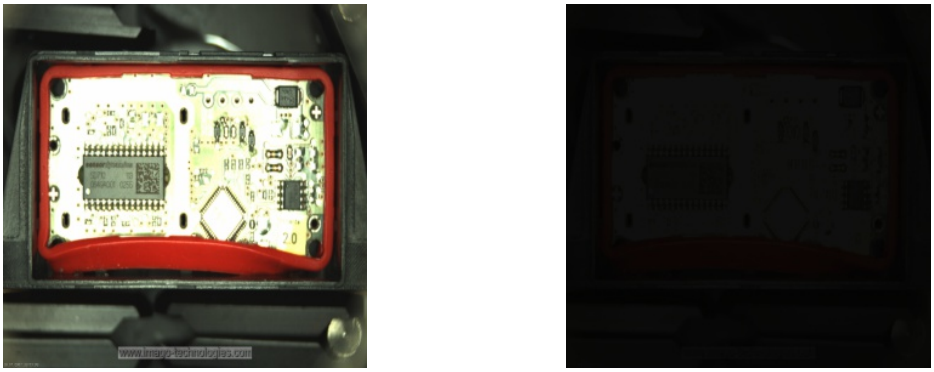
This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

The operation decreases the brightness of an image by transforming each pixel value to its square root.

Examples



*The **SquareRootImage** performed on the sample image.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not an unsigned-valued image in SquareRootImage.
DomainError	Region exceeds an input image in SquareRootImage.
DomainError	Not supported inImage pixel format in SquareRootImage. Supported formats: UInt8, UInt16.

See Also

- SquareImage - Raises pixel values to the second power pixel by pixel.

SubtractFromImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Subtracts a scalar value from each pixel.

Syntax

```
void avl::SubtractFromImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inValue	float	50.0f	Value to be subtracted
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

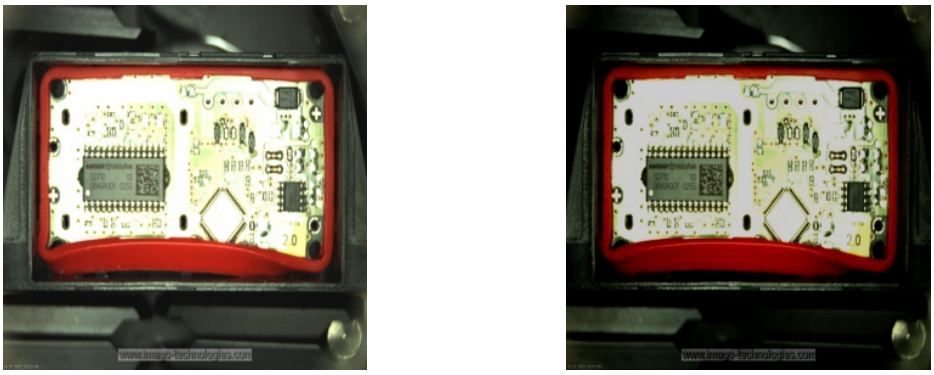
Description

The operation decreases the brightness of the **inImage** by subtracting a fixed value from each of its pixels.

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \mathrm{InImage}_{i,j} - \mathrm{inValue}$$

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value.

Examples



*The **SubtractFromImage** performed on the sample image with **inValue** = 50.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SubtractFromImage.

ExtractText

Header: AVL.h
Namespace: avl
Module: OCR

Ready-to-use tool for extracting and splitting character to single characters.

Syntax

```
void avl::ExtractText
(
 const avl::Image& inImage,
 const avl::Rectangle2D& inRoi,
 const avl::CoordinateSystem2D& inRoiAlignment,
 const avl::TextSegmentation& inSegmentationModel,
 atl::Array<avl::Region>& outCharacters,
 avl::Region& diagTextRegion,
 atl::Array<avl::Region>& diagAlignedCharacters,
 avl::Rectangle2D& diagAlignedRoi
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		An input image with text
→	inRoi	const Rectangle2D&		Location of the text
→	inRoiAlignment	const CoordinateSystem2D&		Adjusts the region of interest to the position of the inspected object
→	inSegmentationModel	const TextSegmentation&		Model used for separating text from background
←	outCharacters	Array<Region>&		Split characters aligned to ROI
🔍	diagTextRegion	Region&		Region of text after extraction
🔍	diagAlignedCharacters	Array<Region>&		Character regions preserving original image orientation
🔍	diagAlignedRoi	Rectangle2D&		ROI rectangle after alignment

Description

This filter distinguish characters from the background using a set of algorithms. This filter performs two steps: text extraction and text segmentation:

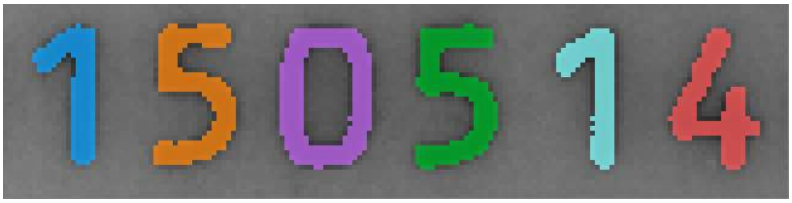
- **Text extraction** – in this step filter uses some basic thresholding methods to get a characters region from the image.
- **Text segmentation** – split previously found region into separate regions contains character.

Input **inRoi** should contains only a single line of text.

Hints

- If the object location is variable, pass an appropriate local coordinate system to **inRoiAlignment**.
- Before defining **inSegmentationModel** first specify **inRoi** – the rectangle in which characters will be extracted.

Examples



Result of reading text using the ExtractText.

Remarks

To read more about how to use traditional OCR technique, refer to Machine Vision Guide: Optical Character Recognition – traditional method

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid segmentation algorithm in ExtractText.
DomainError	Invalid thresholding algorithm in ExtractText.

See Also

- ReadText – Ready-to-use tool for reading text from images using the OCR technique.
- RecognizeCharacters – Classifies input regions into characters. Based on the Multi-Layer Perceptron model.

ExtractText2

Header: AVL.h
Namespace: avl
Module: OCR

Ready-to-use tool for extracting and splitting text elements to single characters.

Syntax

```
void avl::ExtractText2
(
 const avl::Image& inImage,
 const avl::Rectangle2D& inRoi,
 const avl::CoordinateSystem2D& inRoiAlignment,
 const avl::Polarity::Type inPolarity,
 const int inCharWidth,
 atl::Optional<int> inStrokeWidth,
 atl::Optional<int> inMinWordGap,
 atl::Array<avl::Region>& outCharacters,
 atl::Array<avl::Region>& diagAlignedCharacters
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			An input image with text
→	inRoi	const Rectangle2D&			Location of the text
→	inRoiAlignment	const CoordinateSystem2D&			Adjusts the region of interest to the position of the inspected object
→	inPolarity	const Polarity::Type			Text polarity
→	inCharWidth	const int	5 – 200	50	Width of a single character in pixels
→	inStrokeWidth	Optional<int>	1 – 50	NIL	Width of the stroke of the letters in pixels
→	inMinWordGap	Optional<int>	1 – 200	NIL	Width of the smallest gap between letters that is to be treated as a space in pixels
←	outCharacters	Array<Region>&			Regions representing individual characters aligned to the ROI
🔍	diagAlignedCharacters	Array<Region>&			Regions representing individual characters aligned to the Image

Errors

List of possible exceptions:

Error type	Description
DomainError	inPolarity must be specified as Dark or Bright in ExtractText2.
DomainError	inRoi is to narrow to fit a single character in ExtractText2.
DomainError	It is impossible for inStrokeWidth to be greater than inCharWidth in ExtractText2.

GroupRegionsByLines

Header: AVL.h
Namespace: avl
Module: OCR

Splits an array of blobs by distance to computed base lines.

Syntax

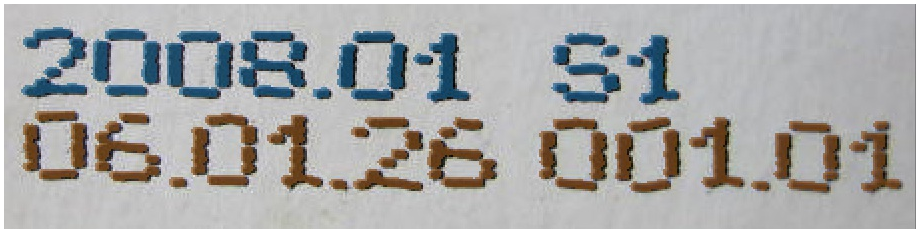
```
void avl::GroupRegionsByLines
(
 const atl::Array<avl::Region>& inRegions,
 const avl::Rectangle2D& inRoi,
 const atl::Optional<avl::CoordinateSystem2D>& inRoiAlignment,
 const int inLinesCount,
 const float inLineWidth,
 const bool inRemoveOutliers,
 atl::Array<atl::Array<avl::Region>>& outLines,
 atl::Array<avl::Region>& outLine0,
 atl::Array<avl::Region>& outLine1,
 atl::Array<avl::Region>& outLine2,
 atl::Array<avl::Region>& outLine3,
 avl::Rectangle2D& outAlignedRoi,
 atl::Array<avl::Segment2D>& diagLines,
 atl::Array<avl::Rectangle2D>& diagLineRanges,
 atl::Array<avl::Point2D>& diagRegionPoints
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegions	const Array<Region>&			Input regions (parts of characters)
→	inRoi	const Rectangle2D&			Range of character classification
→	inRoiAlignment	const Optional<CoordinateSystem2D>&		NIL	
→	inLinesCount	const int	0 – ∞	1	ROI is divided into inLinesCount lines
→	inLineWidth	const float	0.0 – ∞	1.0f	Value of line range used if inRemoveOutliers is set to TRUE
→	inRemoveOutliers	const bool		False	If this flag is set blobs with distance greater than inLineWidth are removed.
←	outLines	Array<Array<Region>>&			Lines in single Array
←	outLine0	Array<Region>&			
←	outLine1	Array<Region>&			
←	outLine2	Array<Region>&			
←	outLine3	Array<Region>&			
←	outAlignedRoi	Rectangle2D&			
🔍	diagLines	Array<Segment2D>&			Segments which indicates the position of lines
🔍	diagLineRanges	Array<Rectangle2D>&			Rectangles represents range of lines which are included if inRemoveOutliers is set
🔍	diagRegionPoints	Array<Point2D>&			Point which indicates region position

Examples

As you can see in the below picture, the filter's task is to divide the input region into several sub-regions by its placement in a line. As a result, each line represents a separate region.



Exemplary result of the filter's usage.

LoadOcrMlpModel

Header: AVL.h
Namespace: avl
Module: OCR

Loads serialized OcrMlpModel object from AVDATA file.

Syntax

```
void avl::LoadOcrMlpModel
(
 const atl::File& inFilename,
 avl::OcrMlpModel& outOcrModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outOcrModel	OcrMlpModel&		Deserialized OcrMlpModel

LoadOcrModel

Header: AVL.h
Namespace: avl
Module: OCR

Loads serialized OcrMlpModel object from AVDATA file.

Syntax

```
void avl::LoadOcrModel
(
 const atl::File& inFilename,
 avl::OcrModel& outOcrModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outOcrModel	OcrModel&		Deserialized OcrMlpModel

LoadOcrSvmModel

Header: AVL.h
Namespace: avl
Module: OCR

Loads serialized OcrSvmModel object from AVDATA file.

Syntax

```
void avl::LoadOcrSvmModel
(
 const atl::File& inFilename,
 avl::OcrSvmModel& outOcrModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outOcrModel	OcrSvmModel&		Deserialized OcrSvmModel

OcrMlpModelToOcrModel

Header: AVL.h
Namespace: avl
Module: OCR

Converts OcrMlpModel(old type) to OcrModel.

Syntax

```
void avl::OcrMlpModelToOcrModel
(
 const avl::OcrMlpModel& inOcrMlpModel,
 avl::OcrModel& outOcrModel
)
```

Parameters

	Name	Type	Default	Description
→	inOcrMlpModel	const OcrMlpModel&		
←	outOcrModel	OcrModel&		

OcrModelToOcrMlpModel

Header: AVL.h
Namespace: avl
Module: OCR

Converts OcrModel to OcrMlpModel.

Syntax

```
void avl::OcrModelToOcrMlpModel
(
 const avl::OcrModel& inOcrModel,
 avl::OcrMlpModel& outOcrMlpModel
)
```

Parameters

	Name	Type	Default	Description
→	inOcrModel	const OcrModel&		
←	outOcrMlpModel	OcrMlpModel&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Provided OcrModel does not contain SVM model.

OcrModelToOcrSvmModel

Header: AVL.h
Namespace: avl
Module: OCR

Converts OcrModel to OcrSvmModel.

Syntax

```
void avl::OcrModelToOcrSvmModel
(
 const avl::OcrModel& inOcrModel,
 avl::OcrSvmModel& outOcrSvmModel
)
```

Parameters

	Name	Type	Default	Description
→	inOcrModel	const OcrModel&		
←	outOcrSvmModel	OcrSvmModel&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Provided OcrModel does not contain SVM model.

OcrSvmModelToOcrModel

Header: AVL.h
Namespace: avl
Module: OCR

Converts OcrSvmModel(old type) to OcrModel.

Syntax

```
void avl::OcrSvmModelToOcrModel
(
 const avl::OcrSvmModel& inOcrSvmModel,
 avl::OcrModel& outOcrModel
)
```

Parameters

	Name	Type	Default	Description
→	inOcrSvmModel	const OcrSvmModel&		
←	outOcrModel	OcrModel&		

ReadText

Header: AVL.h
Namespace: avl
Module: OCR

Ready-to-use tool for reading text from images using the OCR technique.

Syntax

```
void avl::ReadText
(
 const atl::Array<avl::Region>& inCharacters,
 const avl::OcrModel& inOcrModel,
 const float inMinScore,
 atl::String& outText,
 atl::Array<atl::Conditional<atl::String>>& outCharacters,
 atl::Array<float>& outScores,
 bool& outIsTextValid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCharacters	const Array<Region>&			Character regions
→	inOcrModel	const OcrModel&			OCR model specific to a particular font
→	inMinScore	const float	0.0 – 1.0		Minimal score of reading a character
←	outText	String&			Read text
←	outCharacters	Array<Conditional<String>>&			Array of characters. NIL indicates invalid read when inMinScore is set,
←	outScores	Array<float>&			Reading scores for each character
←	outIsTextValid	bool&			Returns False if any character score is smaller than inMinScore

Description

This operation reads a text from the array of regions. Each region corresponds to a single letter at the filter output **outText**. Empty regions are omitted.

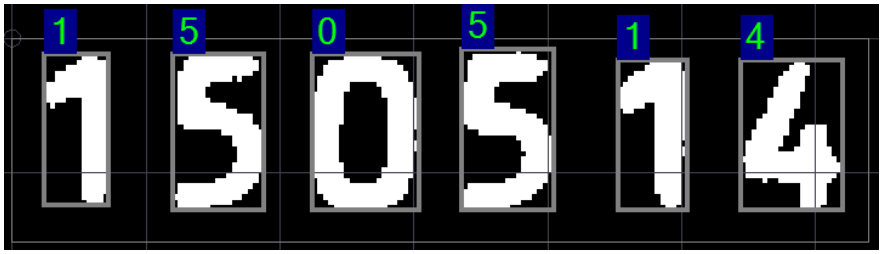
This filter uses a trained OcrModel which can be created using the TrainOcr_MLP or TrainOcr_SVM filter.

Typically this filter are connected with ExtractText which prepares input regions for reading.

Hints

- Pass an array of character regions to the **inCharacters** input. Usually it will be the output of the ExtractText filter.

Examples



Result of reading text using the ReadText and ExtractText.

Remarks

To read more about how to use traditional OCR technique, refer to Machine Vision Guide: Optical Character Recognition – traditional method

Errors

List of possible exceptions:

Error type	Description
DomainError	Uninitialized OCR model in ReadText. OCR model must be trained before use.

See Also

- ExtractText – Ready-to-use tool for extracting and splitting character to single characters.
- RecognizeCharacters – Classifies input regions into characters. Based on the Multi-Layer Perceptron model.
- TrainOcr_MLP – Trains an OCR multilayer perceptron classifier.
- TrainOcr_SVM – Trains an OCR support vector machines classifier.

RecognizeCharacters

Header: AVL.h
Namespace: avl
Module: OCR

Classifies input regions into characters. Based on the Multi-Layer Perceptron model.

Applications: Usually the last, yet the most important step of optical character recognition or verification.

Syntax

```
void avl::RecognizeCharacters
(
 const atl::Array<avl::Region>& inCharacterRegions,
 const avl::OcrModel& inOcrModel,
 atl::Optional<const avl::Size&> inCharacterSize,
 const bool inDotPrint,
 const avl::CharacterSortingOrder::Type inCharacterSorting,
 atl::Optional<float> inMinScore,
 atl::Optional<int> inMinSpaceWidth,
 atl::String& outCharacters,
 atl::Array<float>& outScores,
 atl::Array<atl::Array<avl::OcrCandidate> >& outCandidates,
 atl::Array<avl::Image>& diagNormalizedCharacters,
 atl::Array<avl::Box>& diagCharactersBoxes
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCharacterRegions	const Array<Region>&			Array of character regions to recognize
→	inOcrModel	const OcrModel&			Trained OcrMlpModel used to recognize characters
→	inCharacterSize	Optional<const Size&>		NIL	Size of single monospaced character if needed
→	inDotPrint	const bool			Dot-printed characters preprocessing
→	inCharacterSorting	const CharacterSortingOrder::Type		LeftToRight	Sorting order of input characters
→	inMinScore	Optional<float>	0.0 – 1.0	NIL	Minimal value of accepted result. Otherwise char '*' will be placed.
→	inMinSpaceWidth	Optional<int>	0 – ∞	NIL	Minimal distance between characters where space character will be inserted
←	outCharacters	String&			Result of characters recognition
←	outScores	Array<float>&			Classification result score
←	outCandidates	Array<Array<OcrCandidate> >&			Array of a character classification results and their score
🔍	diagNormalizedCharacters	Array<Image>&			Images of normalized characters used in character recognition
🔍	diagCharactersBoxes	Array<Box>&			Bounding boxes of characters

Description

This operation performs reading a text from a set of regions. This operation requires a trained OCR classifier, which can be created using the TrainOcr_MLP or TrainOcr_SVM filter.

Filter requires regions specified in the **inCharacterRegions**. Each of the input region must contain single character. To get regions from an image use filter ExtractText.

The **inCharacterSorting** parameter defines the sorting order of the input characters provided in **inCharacterRegions**.

The parameter **inDotPrint** turns on the dedicated smoothing for characters printed using a jet printer in a dot-matrix form.

The parameter **inCharacterSize** defines size of monospaced (fixed-width) font. This size defines the cutting character bounding box.

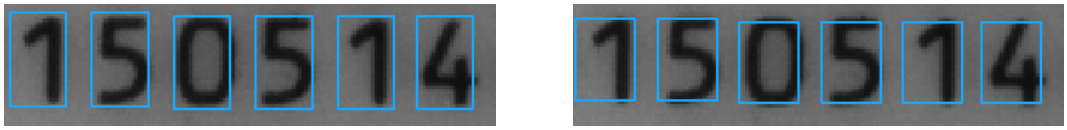


Image shows extracted character cutting boxes with different cutting size.

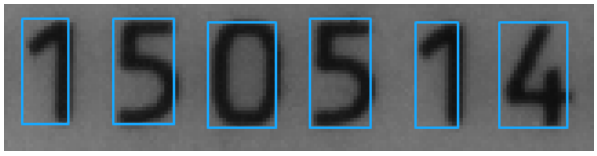
If the parameter is set to *auto* character will be recognized as proportional font. For further information about font types please refer to the documentation of filters TrainOcr_SVM or TrainOcr_MLP.



*Characters boxes with **inCharacterSize** set to **Auto**.*

The input **inMinSpaceWidth** value indicates a minimal distance between characters where space character will be inserted to result string. When the value is marked as **Auto** no spaces will be inserted. Distance is presented in pixels.

If **inMinScore** is set, the characters with smaller score will be replaced with *****

The output **outCharacters** contains recognized characters. The recognition score of each recognized character is stored in the **outScores**.

Remarks

To read more about how to use traditional OCR technique, refer to Machine Vision Guide: Optical Character Recognition - traditional method

Errors

List of possible exceptions:

Error type	Description
DomainError	Uninitialized OCR model in RecognizeCharacters. OCR model must be trained before use.

SaveOcrMlpModel

Header: AVL.h
Namespace: avl
Module: OCR

Saves serialized OcrMlpModel object as AVDATA file.

Syntax

```
void avl::SaveOcrMlpModel
(
 const avl::OcrMlpModel& inOcrModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inOcrModel	const OcrMlpModel&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SaveOcrModel

Header: AVL.h
Namespace: avl
Module: OCR

Saves serialized OcrMlpModel object as AVDATA file.

Syntax

```
void avl::SaveOcrModel
(
 const avl::OcrModel& inOcrModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inOcrModel	const OcrModel&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SaveOcrSvmModel

Header: AVL.h
Namespace: avl
Module: OCR

Saves serialized OcrSvmModel object as AVDATA file.

Syntax

```
void avl::SaveOcrSvmModel
(
 const avl::OcrSvmModel& inOcrModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inOcrModel	const OcrSvmModel&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SplitRegionIntoExactlyNCharacters

Header: AVL.h
Namespace: avl
Module: OCR

Splits the input region into a fixed-size array of regions corresponding to individual characters.

Applications: Text segmentation when the number of characters is known, usually followed by a RecognizeCharacters filter.

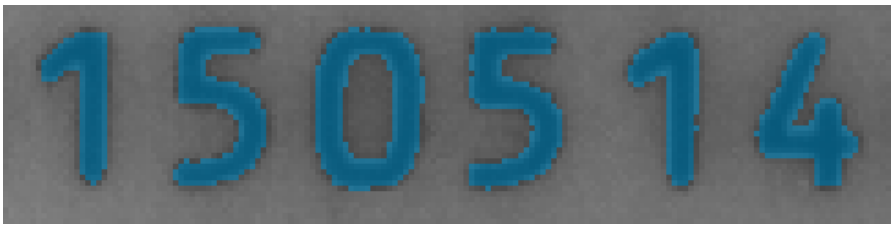
Syntax

```
void avl::SplitRegionIntoExactlyNCharacters
(
 const avl::Region& inRegion,
 const int inCharacterCount,
 const int inCharacterSpacing,
 const float inProjectionSmooth,
 atl::Conditional<atl::Array<avl::Region> >& outRegions,
 atl::Array<avl::Region>& diagClasses,
 avl::Profile& diagProjection
)
```

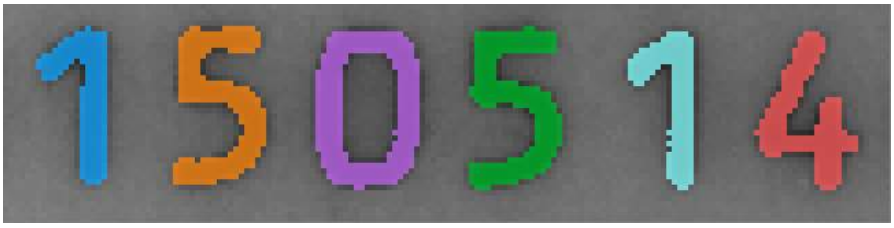
Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Region which contains characters
→	inCharacterCount	const int	1 – ∞		Character count in provided region
→	inCharacterSpacing	const int	0 – ∞		Spacing size between characters
→	inProjectionSmooth	const float	0.0 – ∞	1.0f	Projection smoothing value used to remove noises from character region
←	outRegions	Conditional<Array<Region> >&			Output array of regions containing separated characters
🔍	diagClasses	Array<Region>&			Regions that contain location of split characters
🔍	diagProjection	Profile&			Profile of region projection used to distinguish characters

Examples



Input region.



Result of the filter's usage.

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inCharacterCount is greater than inRegion frame width.
DomainError	Value of inCharactersSpacing is greater than single character width.

SplitRegionIntoMultipleCharacters

Header: AVL.h
Namespace: avl
Module: OCR

Splits the input region into an array of regions corresponding to individual characters.

Applications: Text segmentation when the number of characters is unknown, usually followed by a RecognizeCharacters filter.

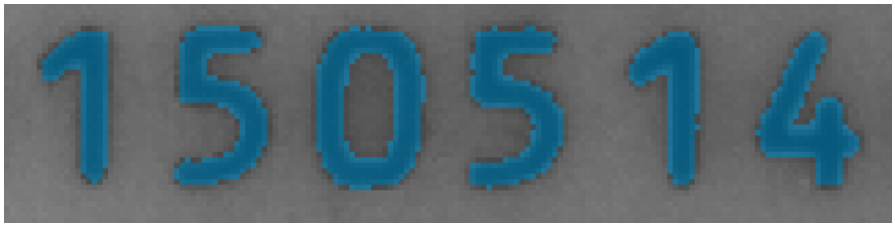
Syntax

```
void avl::SplitRegionIntoMultipleCharacters
(
 const avl::Region& inRegion,
 const float inProjectionSmooth,
 const int inCharacterWidth,
 atl::Array<avl::Region>& outRegions,
 atl::Array<avl::Region>& diagClasses,
 avl::Profile& diagProjection
)
```

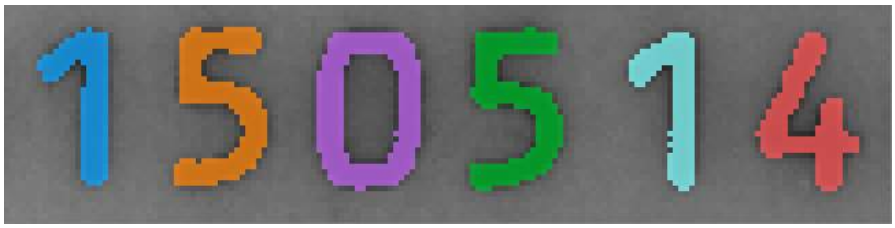
Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region containing characters
→	inProjectionSmooth	const float	0.0 – ∞	1.0f	Value of smooth applied to region projection before splitting into separated characters
→	inCharacterWidth	const int	0 – ∞	15	Single character width
←	outRegions	Array<Region>&			Array or regions containing single characters
🔍	diagClasses	Array<Region>&			Regions in which characters parts will be connected into a single character region
🔍	diagProjection	Profile&			Profile of region projection used to distinguish characters

Examples



Input region.



Result of the filter's usage.

TrainOcr_MLP

Header: AVL.h
Namespace: avl
Module: OCR

Trains an OCR multilayer perceptron classifier.

Syntax

```
void avl::TrainOcr_MLP
(
 const atl::Array<avl::CharacterSample>& inCharacterSamples,
 const avl::Size& inNormalizationSize,
 atl::Optional<const atl::Array<int>& > inHiddenLayerSizes,
 atl::Optional<int> inRandomSeed,
 const avl::CharacterFeatures& inCharacterFeatures,
 float inLearningRate,
 float inMomentum,
 int inIterationCount,
 atl::Optional<const avl::Size&> inCharacterSize,
 avl::OcrModel& outOcrModel,
 float& outTrainingAccuracy,
 avl::Profile& diagError,
 atl::Array<avl::Image>& diagNormalizedCharacters
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCharacterSamples	const Array<CharacterSample>&			Training font created from sample regions
→	inNormalizationSize	const Size&		(Width: 16, Height: 16)	The character size after normalization
→	inHiddenLayerSizes	Optional<const Array<int>& >		NIL	Internal structure of neuron layers used in classifier
→	inRandomSeed	Optional<int>	0 – +∞	NIL	Random seed used by MLP classifier
→	inCharacterFeatures	const CharacterFeatures&		(Pixels: True)	Character features used to distinguish characters from each other
→	inLearningRate	float	0.01 – 1.0	0.6f	Suppression level of changes during learning process
→	inMomentum	float	0.0 – 1.0	0.75f	Value of classifier learning momentum
→	inIterationCount	int	1 – +∞	100	Learning iteration count
→	inCharacterSize	Optional<const Size&>		NIL	Size of fixed width font
←	outOcrModel	OcrModel&			Trained OcrMlpModel used to recognize characters
←	outTrainingAccuracy	float&			The overall training score
🔍	diagError	Profile&			Changes of mean error level progress during learning process
🔍	diagNormalizedCharacters	Array<Image>&			Images of normalized characters used to train classifier

Description

This filter prepares a MLP classifier for the further OCR operations.

Filter requires a set of prepared CharacterSample which can be created using MakeCharacterSamples.

Parameter **inCharacterSize** defines the size of character cropping box. It is especially useful when characters are much bigger than normalization size. When it has **Nil** value the character is cropped to its bounding box.

Parameters **inHiddenLayerSizes**, **inRandomSeed** are used in the process of learning of a newly created MLP classifier. For further parameter description please refer to the documentation of the MLP_Init filter.

All the input regions in filters RecognizeCharacters and TrainOcr_MLP are resized to the size specified in the **inNormalizationSize** input parameter. The further classification is performed on the normalized regions. Therefore, it is important to select the appropriate normalization size.

The selection of too small normalization size may result in loss of character details. However, too large value of normalization size increases the classifier learning time. The best recognition results are obtained when the size of character is nearly the same as the normalization size.

The character classification depends on character features that are selected in the **inCharacterFeatures** parameter. At least one feature must be selected. By the default the feature **Pixels** is selected.

The table below contains the description of each available character feature:

Feature name	Description	Filter origin	Normalized
Pixels	Values of the image pixels after normalization.		False
NormalizedPixels	Values of the image pixels after normalization normalized to range <0, 1.0>.		True
Convexity	Ratio of the input region area to area of its convex hull.	RegionConvexity	True
Circularity	Ratio of the region area to area of its bounding circle.	RegionCircularity	True
NumberOfHoles	Number of holes found in the input region.	RegionHoles	True
AspectRatio	Ratio of input region width to its height.	RegionBoundingBox	False
Width	Region bounding box width.	RegionBoundingBox	False
Height	Region bounding box height.	RegionBoundingBox	False
AreaRatio	Ratio of the input region area to area of its bounding box.		True
DiameterRatio	Ratio of the input region diameter to diameter of its bounding box.	RegionDiameter	True
Elongation	Ratio of longer axis of the approximating ellipse to the shorter one.	RegionElongation	False
Orientation	Further details in the filter RegionOrientation documentation.	RegionOrientation	True
Zoning4x4	Normalized pixel values of region reduced to size 4x4 pixel.		True
HorizontalProjection	Values of normalized image projection normalized by region height.	ImageProjection	True
VerticalProjection	Values of normalized image projection normalized by region height.	ImageProjection	True
HoughCircles	Count of circles found in the normalized image.		True
Moment_11	Character geometric moment type M_{11}.	RegionMoment	False
Moment_20	Character geometric moment type M_{20}.	RegionMoment	False
Moment_02	Character geometric moment type M_{02}.	RegionMoment	False

Remarks

It is recommended not to set normalization size greater than 50 pixels in each dimension. That could make learning time too long.

For more remarks about using MLP classifier please refer to the documentation of the MLP_Init filter.

To read more about how to use traditional OCR technique, refer to Machine Vision Guide: Optical Character Recognition – traditional method

Errors

List of possible exceptions:

Error type	Description
DomainError	At least a single feature must be selected in inCharacterFeatures in TrainOcr_MLP.
DomainError	Hidden layer should have at least a single hidden layer in TrainOcr_MLP.
DomainError	Invalid character sample in TrainOcr_MLP.
DomainError	Invalid normalization size in InitOcr_MLP.

TrainOcr_SVM

Header: AVL.h
Namespace: avl
Module: OCR

Trains an OCR support vector machines classifier.

Syntax

```
void avl::TrainOcr_SVM
(
 const atl::Array<avl::CharacterSample>& inCharacterSamples,
 const avl::Size& inNormalizationSize,
 const atl::Optional<float>& inNu,
 const atl::Optional<float>& inKernelGamma,
 const float inRegularizationConstant,
 const float inStopEpsilon,
 bool inUseShrinkingHeuristics,
 atl::Optional<const avl::Size&> inCharacterSize,
 atl::Optional<int> inRandomSeed,
 const avl::CharacterFeatures& inCharacterFeatures,
 avl::OcrModel& outOcrModel,
 float& outTrainingAccuracy,
 atl::Array<avl::Image>& diagNormalizedCharacters
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inCharacterSamples	const Array<CharacterSample>&			Training font created from sample regions
➡	inNormalizationSize	const Size&		(Width: 16, Height: 16)	The character size after normalization
➡	inNu	const Optional<float>&	0.0 – 1.0	NIL	Trade-off between training accuracy and number of supported vectors
➡	inKernelGamma	const Optional<float>&		NIL	Gamma parameter for RBF kernel
➡	inRegularizationConstant	const float	0.0 – ∞	1.0f	Preventing overfitting
➡	inStopEpsilon	const float		0.001f	Epsilon for stopping criterion
➡	inUseShrinkingHeuristics	bool		True	Heuristics may speed up computations
➡	inCharacterSize	Optional<const Size&>		NIL	Size of fixed width font
➡	inRandomSeed	Optional<int>	0 – + ∞	NIL	Random seed used to train classifier
➡	inCharacterFeatures	const CharacterFeatures&		(Pixels: True)	Character features used to identify characters
⬅	outOcrModel	OcrModel&			Trained OcrSvmModel used to recognize characters
⬅	outTrainingAccuracy	float&			The overall training score
🔍	diagNormalizedCharacters	Array<Image>&			Images of normalized characters used to train classifier

ControlEdgeModelLimits

Header: AVL.h
Namespace: avl
Module: MatchingPro

Limits the size of the EdgeModel objects created by CreateEdgeModel filter.

Syntax

```
void avl::ControlEdgeModelLimits
(
 atl::Optional<int> inSoftMemoryLimit,
 atl::Optional<int> inHardMemoryLimit,
 bool& outHardMemoryLimitViolationStatus
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSoftMemoryLimit	Optional<int>	1 – ∞	NIL	Maximum number of megabytes an EdgeModel can have
→	inHardMemoryLimit	Optional<int>	1 – ∞	NIL	Maximum number of megabytes an EdgeModel creation function can take
←	outHardMemoryLimitViolationStatus	bool&			Flag indicating whether the memory limit was violated recently

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

CreateEdgeModel1

Header: AVL.h
Namespace: avl
Module: MatchingPro

Creates a model for edge-based template matching.

Applications: Dynamic creation of models in the runtime environment (normally they are created interactively in Studio).

Syntax

```
void avl::CreateEdgeModel1
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inTemplateRegion,
 atl::Optional<const avl::Rectangle2D&> inReferenceFrame,
 int inMinPyramidLevel,
 atl::Optional<int> inMaxPyramidLevel,
 float inSmoothingStdDev,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 float inMinAngle,
 float inMaxAngle,
 float inAnglePrecision,
 float inMinScale,
 float inMaxScale,
 float inScalePrecision,
 float inEdgeCompleteness,
 atl::Conditional<avl::EdgeModel>& outEdgeModel,
 atl::Optional<atl::Conditional<avl::Point2D>&> outEdgeModelPoint = atl::NIL,
 atl::Optional<atl::Conditional<atl::Array<avl::Path>>&> outEdges = atl::NIL,
 atl::Conditional<atl::Array<avl::Image> >& diagEdgePyramid
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Image from which model will be extracted
➡	inTemplateRegion	Optional<const Region&>		NIL	Region of the image from which model will be extracted
➡	inReferenceFrame	Optional<const Rectangle2D&>		NIL	Exact position of the model object in the image
➡	inMinPyramidLevel	int	0 – 12	0	Defines the index of the lowest reduced resolution level used to speed up computations
➡	inMaxPyramidLevel	Optional<int>	0 – 12	NIL	Defines the number of reduced resolution levels used to speed up computations
➡	inSmoothingStdDev	float	0.0 – ∞	0.0f	Standard deviation of the gaussian smoothing applied before edge extraction
➡	inEdgeThreshold	float	0.0 – ∞	35.0f	Higher threshold for edge magnitude
➡	inEdgeHysteresis	float	0.0 – ∞	15.0f	Threshold hysteresis value for edge magnitude
➡	inMinAngle	float		-180.0f	Start of range of possible rotations
➡	inMaxAngle	float		180.0f	End of range of possible rotations
➡	inAnglePrecision	float	0.001 – 10.0	1.0f	Defines angular resolution of the matching process
➡	inMinScale	float	0.0 – ∞	1.0f	Start of range of possible scales
➡	inMaxScale	float	0.0 – ∞	1.0f	End of range of possible scales
➡	inScalePrecision	float	0.001 – 10.0	1.0f	Defines scale resolution of the matching process
➡	inEdgeCompleteness	float	0.01 – 1.0	1.0f	Determines what fraction of the edges will be present in the created model
⬅	outEdgeModel	Conditional<EdgeModel>&			Created model that can be used by LocateMultipleObjects_Edges
⬅	outEdgeModelPoint	Optional<Conditional<Point2D>&>		NIL	The middle point of the created model
⬅	outEdges	Optional<Conditional<Array<Path>>&>		NIL	Visualization of the model edges found at the original resolution
🔍	diagEdgePyramid	Conditional<Array<Image> >&			Visualization of the edges found at different resolution levels

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdgeModelPoint**, **outEdges**.

Read more about Optional Outputs.

Description

The operation creates an Edge Matching model for the object represented in **inTemplateRegion** region in **inImage** image. The resulting model can be matched against any image using the LocateMultipleObjects_Edges1 filter.

The model consists of a pyramid of iteratively downsampled images, the original image being the first of them. The **inMaxPyramidLevel** parameter determines how many additional images of the pyramid shall be computed. Its value has great influence on computation speed. Therefore it is highly recommended to set its value as high as possible, at the same time ensuring that the model edges are at least 2^**inMaxPyramidLevel** pixels far from the **inImage** image frame. However, if it is set too high and no model edges are found on some pyramid level, an error with appropriate description occurs.

The **inEdgeThreshold** and **inEdgeHysteresis** parameters control the hysteresis threshold (as in ThresholdImage_Hysteresis) used in the edge extraction (as in DetectEdges_AsRegion) phase of the model creation. It is an important part of using the filter to set these parameters properly, because only found edge pixels determine how good the later matching process will be. Therefore the **outEdges** and **diagEdgePyramid** are the crucial parameters for experiments, because they show found edges in the model image and edge pixels found at different resolution levels, respectively.

The **inMinAngle** and **inMaxAngle** parameters describe possible rotation angles of the model, i.e. only those object occurrences will be later found by LocateMultipleObjects_Edges1 whose rotation angles are in the range <**inMinAngle**,**inMaxAngle**>. The **inAnglePrecision** parameter controls the angular resolution of the matching process. The model is created in several rotations. The angles of consecutive rotations differ by an angle step from each other. The value of this angle step is determined on the basis of **inAnglePrecision**. Its value represents the multiplicity of the automatically computed angle step used as an actual step. So the greater **inAnglePrecision** is, the greater accuracy can be achieved and the lower is the chance of missing object occurrences. In practice however increasing **inAnglePrecision** above a certain threshold (unique for every object) does not increase the accuracy, only the computation time.

The **inReferenceFrame** is a characteristic rectangle, the position of which will be returned by LocateMultipleObjects_Edges1 as an occurrence of the object. By default, it is set to the bounding box of the edges found in **inTemplateRegion**.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Additional information about Template Matching can be found in Machine Vision Guide: Template Matching

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect scale range in CreateEdgeModel.
DomainError	Minimal pyramid level cannot be greater than maximal pyramid level in CreateEdgeModel.
DomainError	Region of interest exceeds an input image in CreateEdgeModel.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdgeModelPoint**, **outEdges**.

Read more about Optional Outputs.

Description

The operation creates an Edge-based Template Matching model for the object represented in **inTemplateRegion** region in **inImage** image. The resulting model can be matched against any image using the LocateSingleObject_Edges2 or LocateMultipleObjects_Edges2 filter.

The model consists of a pyramid of iteratively downsampled images, the original image being the first of them. The **inMaxPyramidLevel** parameter determines how many additional images of the pyramid shall be computed. Its value has great influence on computation speed. Therefore it is highly recommended to set its value as high as possible, at the same time ensuring that the model edges are at least 2^**inMaxPyramidLevel** pixels far from the **inImage** image frame. However, if it is set too high and no model edges are found on some pyramid level, an error with appropriate description occurs.

The **inMinPyramidLevel** parameter determines what is the lowest pyramid level that is generated in the filter. Each level lower than that will be generated on demand in a locating objects filter that uses the model.

The **inEdgeThreshold** and **inEdgeHysteresis** parameters control the hysteresis threshold (as in ThresholdImage_Hysteresis) used in the edge extraction (as in DetectEdges_AsRegion) phase of the model creation. It is an important part of using the filter to set these parameters properly, because only found edge pixels determine how good the later matching process will be. Therefore the **outEdges** and **diagEdgePyramid** are the crucial parameters for experiments, because they show found edges in the model image and edge pixels found at different resolution levels, respectively.

The **inMinAngle** and **inMaxAngle** parameters describe possible rotation angles of the model, i.e. only those object occurrences will be later found by LocateMultipleObjects_Edges2 whose rotation angles are in the range <**inMinAngle**,**inMaxAngle**>. The **inAnglePrecision** parameter controls the angular resolution of the matching process. The model is created in several rotations. The angles of consecutive rotations differ by an angle step from each other. The value of this angle step is determined on the basis of **inAnglePrecision**. Its value represents the multiplicity of the automatically computed angle step used as an actual step. So the greater **inAnglePrecision** is, the greater accuracy can be achieved and the lower is the chance of missing object occurrences. In practice however increasing **inAnglePrecision** above a certain threshold (unique for every object) does not increase the accuracy, only the computation time.

The **inReferenceFrame** is a characteristic rectangle, the position of which will be returned by LocateMultipleObjects_Edges2 as an occurrence of the object. By default, it is set to the bounding box of the edges found in **inTemplateRegion**.

CreateEdgeModel_Elastic

Header: AVL.h
Namespace: avl
Module: MatchingPro

Creates a model for edge-based template matching.

Applications: Dynamic creation of models in the runtime environment (normally they are created interactively in Studio).

Syntax

```
void avl::CreateEdgeModel_Elastic
(
 const avl::Image& inImage,

```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which model will be extracted
→	inTemplateRegion	Optional<const Region&>		NIL	Region of the image from which model will be extracted
→	inReferenceFrame	Optional<const Rectangle2D&>		NIL	Exact position of the model object in the image
→	inGradientDifferenceTolerance	AngleDifferenceTolerance::Type		Standard	Determines what gradient angles are considered to be similar
→	inSmoothingStdDev	float	0.0 – ∞	0.0f	Standard deviation of the gaussian smoothing applied before edge extraction
→	inEdgeThreshold	float	0.0 – ∞	35.0f	Higher threshold for edge magnitude
→	inEdgeHysteresis	float	0.0 – ∞	15.0f	Threshold hysteresis value for edge magnitude
→	inMinAngle	float		-180.0f	Start of range of possible rotations
→	inMaxAngle	float		180.0f	End of range of possible rotations
→	inMinScale	float	0.0 – ∞	1.0f	Start of range of possible scales
→	inMaxScale	float	0.0 – ∞	1.0f	End of range of possible scales
←	outEdgeModel	Conditional<EdgeModel_Elastic>&			Created model that can be used by Locate filter
←	outEdgeModelPoint	Optional<Conditional<Point2D>&>		NIL	The middle point of the created model
←	outEdges	Optional<Conditional<Array<Path>>&>		NIL	Visualization of the model edges found at the original resolution

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdgeModelPoint**, **outEdges**.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

CreateGrayModel

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Creates a model for NCC or SAD template matching.

Applications: Dynamic creation of models in the runtime environment (normally they are created interactively in Studio).

Syntax

```
void avl::CreateGrayModel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inTemplateRegion,
 atl::Optional<const avl::Rectangle2D&> inReferenceFrame,
 int inMinPyramidLevel,
 atl::Optional<int> inMaxPyramidLevel,
 float inMinAngle,
 float inMaxAngle,
 float inAnglePrecision,
 float inMinScale,
 float inMaxScale,
 float inScalePrecision,
 avl::GrayModel& outGrayModel,
 atl::Optional<avl::Point2D&> outGrayModelPoint = atl::NIL,
 atl::Array<avl::Image>& diagTemplatePyramid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which model will be extracted
→	inTemplateRegion	Optional<const Region&>		NIL	Region of the image from which model will be extracted
→	inReferenceFrame	Optional<const Rectangle2D&>		NIL	Exact position of the model object in the image
→	inMinPyramidLevel	int	0 – 12	0	Defines the index of the lowest reduced resolution level used to speed up computations
→	inMaxPyramidLevel	Optional<int>	0 – 12	NIL	Defines the number of reduced resolution levels used to speed up computations
→	inMinAngle	float		0.0f	Start of range of possible rotations
→	inMaxAngle	float		0.0f	End of range of possible rotations
→	inAnglePrecision	float	0.001 – 10.0	1.0f	Defines angular resolution of the matching process
→	inMinScale	float	0.0 – ∞	1.0f	Start of range of possible scales
→	inMaxScale	float	0.0 – ∞	1.0f	End of range of possible scales
→	inScalePrecision	float	0.001 – 10.0	1.0f	Defines scale resolution of the matching process
←	outGrayModel	GrayModel&			Created model that can be used by LocateMultipleObjects_NCC and LocateMultipleObjects_SAD filters
←	outGrayModelPoint	Optional<Point2D&>		NIL	The middle point of the created model
🔍	diagTemplatePyramid	Array<Image>&			Visualization of the model at different resolution levels

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outGrayModelPoint**.

Read more about Optional Outputs.

Description

The operation creates a Gray Matching model for the object represented in **inTemplateRegion** region in **inImage** image. The resulting model can be matched against any image using the LocateMultipleObjects_NCC filter or the LocateMultipleObjects_SAD filter.

The model consists of a pyramid of iteratively downsampled images, the original image being the first of them. The **inMaxPyramidLevel** parameter determines how many additional images of the pyramid shall be computed. Greater **inMaxPyramidLevel** values can speed up matching process considerably, but it should be set so the image on the highest pyramid level is not too distorted.

The **inMinAngle** and **inMaxAngle** parameters describe possible rotation angles of the model, i.e. only those object occurrences will be later found by LocateMultipleObjects_NCC (or LocateMultipleObjects_SAD) whose rotation angles are in the range <**inMinAngle**,**inMaxAngle**>. The **inAnglePrecision** parameter controls the angular resolution of the matching process. The model is created in several rotations. The angles of consecutive rotations differ by an angle step from each other. The value of this angle step is determined on the basis of **inAnglePrecision**. Its value represents the multiplicity of the automatically computed angle step used as an actual step. So the greater **inAnglePrecision** is, the greater accuracy can be achieved and the lower is the chance of missing object occurrences. In practice however increasing **inAnglePrecision** above a certain threshold (unique for every object) does not increase the accuracy, only the computation time.

The **inReferenceFrame** is a characteristic rectangle, the position of which will be returned by LocateMultipleObjects_NCC (or LocateMultipleObjects_SAD) as an occurrence of the object. By default, it is set to the bounding box of the **inTemplateRegion**.

Remarks

EdgeModel2ByteSize

Header: AVL.h
Namespace: avl
Module: MatchingPro

Returns estimated size of the EdgeModel2 in bytes.

Syntax

```
void avl::EdgeModel2ByteSize
(
 const avl::EdgeModel2& inEdgeModel,
 atl::int64& outByteSize
)
```

Parameters

	Name	Type	Default	Description
→	inEdgeModel	const EdgeModel2&		
←	outByteSize	int64&		

EdgeModel_ElasticByteSize

Header: AVL.h
Namespace: avl
Module: MatchingPro

Returns estimated size of the EdgeModel_Elastic in bytes.

Syntax

```
void avl::EdgeModel_ElasticByteSize
(
 const avl::EdgeModel_Elastic& inEdgeModel,
 atl::int64& outByteSize
)
```

Parameters

	Name	Type	Default	Description
→	inEdgeModel	const EdgeModel_Elastic&		
←	outByteSize	int64&		

EnhanceMultipleObjectMatches

Header: AVL.h
Namespace: avl
Module: MatchingPro

Improves accuracy of multiple object matching by adding a subpixel-precise adjustment.

Applications: Usually used after an edge-based template matching tool.

Syntax

```
void avl::EnhanceMultipleObjectMatches
(
 const avl::Image& inImage,
 const atl::Array<avl::Object2D>& inObjects,
 const atl::Array<atl::Array<avl::Path>>& inObjectEdges,
 bool inAllowScale,
 atl::Array<avl::Object2D>& outObjects,
 atl::Array<atl::Array<avl::Path>>& outObjectEdges
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inObjects	const Array<Object2D>&		Input objects
→	inObjectEdges	const Array<Array<Path>>&		Input objects edges
→	inAllowScale	bool		Determines if the object scale can be adjusted
←	outObjects	Array<Object2D>&		Objects with enhanced accuracy
←	outObjectEdges	Array<Array<Path>>&		Edges of objects with enhanced accuracy

Hints

- In order to use the filter to fine-tune the results of template matching, connect the **outObjects** and **outObjectEdges** outputs of the template matching filter to the **inObjects** and **inObjectEdges** inputs, and the same input image to the **inImage** input. By default, the **outObjects** and **outObjectEdges** outputs of the template matching filter are hidden, so one should use "Show/Hide Ports" option to make them visible.
- When using template matching with **EnhanceMultipleObjectMatches** filter, you may try to speed up template matching by increasing its **inMinPyramidLevel** parameter. The potential loss of template matching precision should be mitigated by the **EnhanceMultipleObjectMatches** filter.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inObjects and inObjectEdges sizes differ

See Also

- LocateMultipleObjects_Edges1 – Finds all occurrences of a predefined template on an image by comparing object edges.
- EnhanceSingleObjectMatch – Improves accuracy of single object matching by adding a subpixel-precise adjustment.

EnhanceSingleObjectMatch

Header: AVL.h
Namespace: avl
Module: MatchingPro

Improves accuracy of single object matching by adding a subpixel-precise adjustment.

Applications: Usually used after an edge-based template matching tool.

Syntax

```
void avl::EnhanceSingleObjectMatch
(
 const avl::Image& inImage,
 const avl::Object2D& inObject,
 const atl::Array<avl::Path>& inObjectEdges,
 bool inAllowScale,
 avl::Object2D& outObject,
 atl::Array<avl::Path>& outObjectEdges
)
```

Parameters

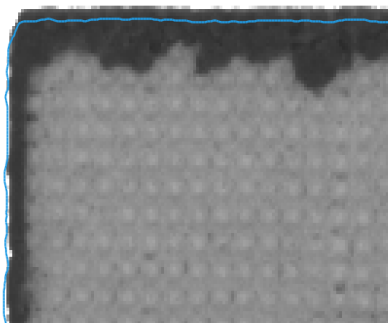
	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inObject	const Object2D&		Input object
→	inObjectEdges	const Array<Path>&		Input object edges
→	inAllowScale	bool		Determines if the object scale can be adjusted
←	outObject	Object2D&		Object with enhanced accuracy
←	outObjectEdges	Array<Path>&		Edges of the object with enhanced accuracy

Hints

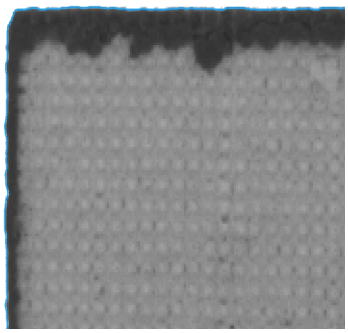
- In order to use the filter to fine-tune the results of template matching, connect the **outObject** and **outObjectEdges** outputs of the template matching filter to the **inObject** and **inObjectEdges** inputs, and the same input image to the **inImage** input. By default, the **outObject** and **outObjectEdges** outputs of the template matching filter are hidden, so one should use "Show/Hide Ports" option to make them visible.

Examples

When using template matching with **EnhanceSingleObjectMatch** filter, you may try to speed up template matching by increasing its **inMinPyramidLevel** parameter. The potential loss of template matching precision should be mitigated by the **EnhanceSingleObjectMatch** filter, as shown in the images below:



Without enhancement



With enhancement

GrayModel2ByteSize

Header: AVL.h
Namespace: avl
Module: MatchingPro

Returns estimated size of the GrayModel2 in bytes.

Syntax

```
void avl::GrayModel2ByteSize
(
 const avl::GrayModel2& inGrayModel,
 atl::int64& outByteSize
)
```

Parameters

	Name	Type	Default	Description
→	inGrayModel	const GrayModel2&		
←	outByteSize	int64&		

LoadEdgeModel

Header: AVL.h
Namespace: avl
Module: MatchingPro

Loads serialized template matching EdgeModel object from AVDATA file.

Syntax

```
void avl::LoadEdgeModel
(
 const atl::File& inFilename,
 avl::EdgeModel& outEdgeModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outEdgeModel	EdgeModel&		Deserialized output model

LoadEdgeModel2

Header: AVL.h
Namespace: avl
Module: MatchingPro

Loads serialized template matching EdgeModel2 object from AVDATA file.

Syntax

```
void avl::LoadEdgeModel2
(
 const atl::File& inFilename,
 avl::EdgeModel2& outEdgeModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outEdgeModel	EdgeModel2&		Deserialized output model

LoadGrayModel

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Loads serialized template matching GrayModel object from AVDATA file.

Syntax

```
void avl::LoadGrayModel
(
 const atl::File& inFilename,
 avl::GrayModel& outGrayModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outGrayModel	GrayModel&		Deserialized output model

LoadGrayModel2

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Loads serialized template matching GrayModel2 object from AVDATA file.

Syntax

```
void avl::LoadGrayModel2
(
 const atl::File& inFilename,
 avl::GrayModel2& outGrayModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outGrayModel	GrayModel2&		Deserialized output model

LocateMultipleObjects_Edges1

Header: AVL.h
Namespace: avl
Module: MatchingPro

Finds all occurrences of a predefined template on an image by comparing object edges.

Applications: Detection of multiple objects whose outlines are sharp and rigid. Often one of the first filters in a program.

Syntax

```
void avl::LocateMultipleObjects_Edges1
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inSearchRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inSearchRegionAlignment,
 const avl::EdgeModel& inEdgeModel,
 int inMinPyramidLevel,
 atl::Optional<int> inMaxPyramidLevel,
 float inEdgeThreshold,
 avl::EdgePolarityMode::Type inEdgePolarityMode,
 avl::EdgeNoiseLevel::Type inEdgeNoiseLevel,
 bool inIgnoreBoundaryObjects,
 float inMinScore,
 float inMinDistance,
 atl::Array<avl::Object2D>& outObjects,
 atl::Optional<atl::Array<atl::Array<avl::Path>>&> outObjectEdges = atl::NIL,
 atl::Optional<int&> outPyramidHeight = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedSearchRegion = atl::NIL,
 atl::Array<avl::Image>& diagEdgePyramid,
 atl::Array<avl::Image>& diagMatchPyramid,
 atl::Array<atl::Array<float> >& diagScores
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Image on which object occurrences will be searched
➡	inSearchRegion	Optional<const ShapeRegion&>		NIL	Region of possible object centers
➡	inSearchRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
➡	inEdgeModel	const EdgeModel&			Model of objects to be searched
➡	inMinPyramidLevel	int	0 – 12	0	Defines the lowest pyramid level at which object position is still refined
➡	inMaxPyramidLevel	Optional<int>	0 – 12	3	Defines the total number of reduced resolution levels that can be used to speed up computations
➡	inEdgeThreshold	float	0.01 – ∞	10.0f	Minimum strength of edges used for matching with the model
➡	inEdgePolarityMode	EdgePolarityMode::Type		MatchStrictly	Defines how edges with reversed polarity will contribute to the object score
➡	inEdgeNoiseLevel	EdgeNoiseLevel::Type		High	Defines how much noise the objects edges have
➡	inIgnoreBoundaryObjects	bool		False	Flag indicating whether objects crossing image boundary should be ignored or not
➡	inMinScore	float	0.0 – 1.0	0.7f	Minimum score of object candidates accepted at each pyramid level
➡	inMinDistance	float	0.0 – ∞	10.0f	Minimum distance between two found objects
⬅	outObjects	Array<Object2D>&			Found objects
⬅	outObjectEdges	Optional<Array<Array<Path>>&>		NIL	Model edges of the found objects
⬅	outPyramidHeight	Optional<int&>		NIL	Highest pyramid level used to speed up computations
⬅	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region
🔍	diagEdgePyramid	Array<Image>&			Image edges used for matching at each pyramid level
🔍	diagMatchPyramid	Array<Image>&			Candidate object locations found at each pyramid level
🔍	diagScores	Array<Array<float> >&			Scores of the found objects at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outObjectEdges**, **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inEdgeModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence. The **inMinDistance** parameter determines minimum distance between any two valid occurrences (if two occurrences lie closer than **inMinDistance** from each other, the one with greater score is considered to be valid).

In the **inImage** every pixel with gradient's magnitude at least **inEdgeThreshold** is considered an edge pixel. Only those are later used during the matching process. To establish the value of this threshold properly the **diagEdgePyramid** output which shows all the edges with sufficient gradient's magnitude may be used. If the **inEdgePolarityMode** parameter is set to Ignore, the object occurrences in the **inImage** image do not have necessarily to have the same contrast as the object in the model image.

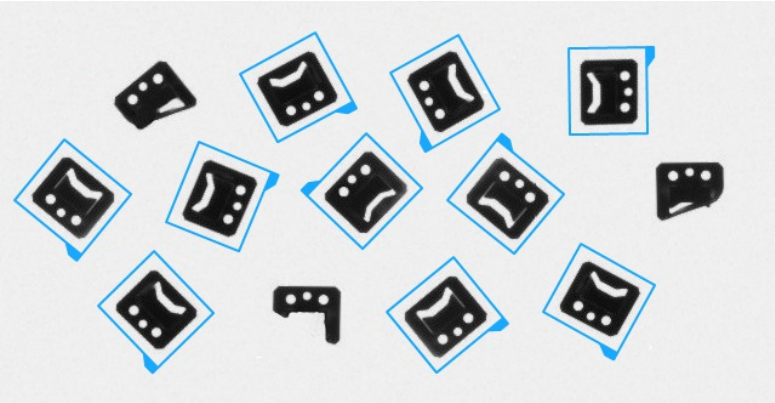
The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

The **outObjects.Point** array contains the model reference points of the matched object occurrences. The corresponding **outObjects.Angle** array contains the rotation angles of the objects. The corresponding **outObjects.Match** array provides information about both the position and the angle of each match combined into value of Rectangle2D type. Each element of the **outObjects.Alignment** array contains informations about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of corresponding **outObjects.Match** position. This array can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- You can use EnhanceMultipleObjectMatches filter to fine-tune the results. A great example of usage is presented in the CreateGoldenTemplate2 filter.
- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision**, **inScalePrecision** and **inEdgeCompleteness**.
- To obtain high accuracy of matching make sure that the edges visible on the **diagEdgePyramid** output are not too thick. Increase **inEdgeThreshold** to make them thinner.
- Also consider increasing **inEdgeThreshold** if there is much noise on the **diagEdgePyramid** output.
- Verify accuracy of the matching by checking the **outObjectEdges** output. If the accuracy is lower than expected, make sure that **inMinPyramidLevel** = 0, try increasing **inEdgeThreshold** and also consider higher values for **inAnglePrecision** during model creation.
- To further improve matching accuracy use the EnhanceMultipleObjectMatches filter.
- If the object being detected can be darker or brighter than the background on different images, use the **inEdgePolarityMode** parameter set to Ignore.
- If the object being detected is only partially visible or its shape and the model shape are not identical, use the **inEdgePolarityMode** parameter set to MatchWeakly.
- If there is only low noise in the object edges, use the **inEdgeNoiseLevel** parameter set to Low.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).

Examples



Locating multiple objects with the edge-based method.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

⬅	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region
🔍	diagEdgePyramid	Array<Image>&			Image edges used for matching at each pyramid level
🔍	diagMatchPyramid	Array<Image>&			Candidate object locations found at each pyramid level
🔍	diagScores	Array<Array<float> >&			Scores of the found objects at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outObjectEdges**, **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inEdgeModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence. The **inMinDistance** parameter determines minimum distance between any two valid occurrences (if two occurrences lie closer than **inMinDistance** from each other, the one with greater score is considered to be valid).

In the **inImage** every pixel with gradient's magnitude at least **inEdgeThreshold** is considered an edge pixel. Only those are later used during the matching process. To establish the value of this threshold properly the **diagEdgePyramid** output which shows all the edges with sufficient gradient's magnitude may be used. If the **inEdgePolarityMode** parameter is set to Ignore, the object occurrences in the **inImage** image do not have necessarily to have the same contrast as the object in the model image.

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

The **outObjects.Point** array contains the model reference points of the matched object occurrences. The corresponding **outObjects.Angle** array contains the rotation angles of the objects. The corresponding **outObjects.Match** array provides information about both the position and the angle of each match combined into value of Rectangle2D type. Each element of the **outObjects.Alignment** array contains informations about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of corresponding **outObjects.Match** position. This array can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- You can use EnhanceMultipleObjectMatches filter to fine-tune the results. A great example of usage is presented in the CreateGoldenTemplate2 filter.
- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision**, **inScalePrecision** and **inEdgeCompleteness**.
- To obtain high accuracy of matching make sure that the edges visible on the **diagEdgePyramid** output are not too thick. Increase **inEdgeThreshold** to make them thinner.
- Also consider increasing **inEdgeThreshold** if there is much noise on the **diagEdgePyramid** output.
- Verify accuracy of the matching by checking the **outObjectEdges** output. If the accuracy is lower than expected, make sure that **inMinPyramidLevel** = 0, try increasing **inEdgeThreshold** and also consider higher values for **inAnglePrecision** during model creation.
- To further improve matching accuracy use the EnhanceMultipleObjectMatches filter.
- If the object being detected can be darker or brighter than the background on different images, use the **inEdgePolarityMode** parameter set to Ignore.
- If the object being detected is only partially visible or its shape and the model shape are not identical, use the **inEdgePolarityMode** parameter set to MatchWeakly.
- If there is only low noise in the object edges, use the **inEdgeNoiseLevel** parameter set to Low.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).

Examples

Locating multiple objects with the edge-based method.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Additional information about Template Matching can be found in Machine Vision Guide: Template Matching

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

LocateMultipleObjects_Elastic

Header: AVL.h
Namespace: avl
Module: MatchingPro

Finds all occurrences of a predefined template on an image by comparing object edges.

Applications: Detection of multiple objects whose outlines are sharp and rigid. Often one of the first filters in a program.

Syntax

```
void avl::LocateMultipleObjects_Elastic
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inSearchRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inSearchRegionAlignment,
 const avl::EdgeModel_Elastic& inEdgeModel,
 avl::ElasticMatchingDetectionStrategy::Type inDetectionStrategy,
 float inEdgeThreshold,
 float inMinAspectRatio,
 float inMaxAspectRatio,
 float inMinScore,
 atl::Array<avl::Object2D>& outObjects,
 atl::Array<atl::Array<avl::Path>>& outObjectEdges,
 atl::Optional<avl::ShapeRegion&> outAlignedSearchRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image on which object occurrences will be searched
→	inSearchRegion	Optional<const ShapeRegion&>		NIL	Region of possible object centers
→	inSearchRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inEdgeModel	const EdgeModel_Elastic&			Model of objects to be searched
→	inDetectionStrategy	ElasticMatchingDetectionStrategy::Type		Fast	Specifies initial candidates detection mode
→	inEdgeThreshold	float	0.1 – ∞	10.0f	Minimum strength of edges used for matching with the model
→	inMinAspectRatio	float	0.5 – 2.0	1.0f	Minimum expected aspect ratio of object occurrence being found
→	inMaxAspectRatio	float	0.5 – 2.0	1.0f	Maximum expected aspect ratio of object occurrence being found
→	inMinScore	float	0.0 – 1.0	0.7f	Minimum score of an object occurrence
←	outObjects	Array<Object2D>&			Found objects
←	outObjectEdges	Array<Array<Path>>&			Model edges of the found objects
←	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedSearchRegion**.

🔍	diagScores	Array<Array<float>>&			Scores of the found objects at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inGrayModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence. The **inMinDistance** parameter determines minimum distance between any two valid occurrences (if two occurrences lie closer than **inMinDistance** from each other, the one with greater score is considered to be valid).

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

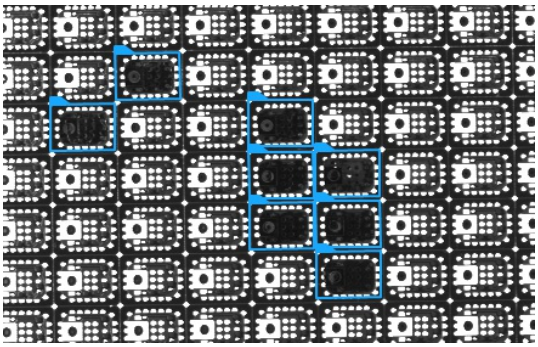
To be able to locate objects which are partially outside the image, the filter assumes that there are only black pixels beyond the image border.

The **outObjects.Point** array contains the model reference points of the matched object occurrences. The corresponding **outObjects.Angle** array contains the rotation angles of the objects. The corresponding **outObjects.Match** array provides information about both the position and the angle of each match combined into value of Rectangle2D type. Each element of the **outObjects.Alignment** array contains informations about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of corresponding **outObjects.Match** position. This array can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**. However, if you need to lower **inMinScore** below 0.5, then probably something else is wrong.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision** and **inScalePrecision**.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).
- Smoothing of the input image can significantly improve performance of this tool.

Examples



*Locating multiple objects with the gray-based method (**inMaxPyramidLevel** = 2). Please note, that the edge-based method might not work properly here, because what we are looking for (a missing chip) is a sub-object of what we are not looking for (a correct chip).*

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inGrayModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMaxDifference** parameter determines the maximum average difference between corresponding pixel values of the valid object occurrence. The **inMinDistance** parameter determines minimum distance between any two valid occurrences (if two occurrences lie closer than **inMinDistance** from each other, the one with greater score is considered to be valid).

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMaxDifference**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Lower **inMaxDifference** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

To be able to locate objects which are partially outside the image, the filter assumes that there are only black pixels beyond the image border.

The **outObjects.Point** array contains the model reference points of the matched object occurrences. The corresponding **outObjects.Angle** array contains the rotation angles of the objects. The corresponding **outObjects.Match** array provides information about both the position and the angle of each match combined into value of Rectangle2D type. Each element of the **outObjects.Alignment** array contains informations about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of corresponding **outObjects.Match** position. This array can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

The SAD (Sum of Absolute Differences) method can be significantly slower than NCC (Normalized Cross-Correlation) method. Moreover, it is not illumination-invariant, as it is required in most applications. Thus, it is highly recommended to use the latter, NCC method instead.

Remarks

LocateSingleObject_Edges1

Header: AVL.h
Namespace: avl
Module: MatchingPro

Finds a single occurrence of a predefined template on an image by comparing object edges.

Applications: Detection of an object whose outlines are sharp and rigid. Often one of the first filters in a program.

Syntax

```
void avl::LocateSingleObject_Edges1
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inSearchRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inSearchRegionAlignment,
 const avl::EdgeModel& inEdgeModel,
 int inMinPyramidLevel,
 atl::Optional<int> inMaxPyramidLevel,
 float inEdgeThreshold,
 avl::EdgePolarityMode::Type inEdgePolarityMode,
 avl::EdgeNoiseLevel::Type inEdgeNoiseLevel,
 bool inIgnoreBoundaryObjects,
 float inMinScore,
 atl::Conditional<avl::Object2D>& outObject,
 atl::Optional<atl::Conditional<atl::Array<avl::Path>>&> outObjectEdges = atl::NIL,
 atl::Optional<int&> outPyramidHeight = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedSearchRegion = atl::NIL,
 atl::Array<avl::Image>& diagEdgePyramid,
 atl::Array<avl::Image>& diagMatchPyramid,
 atl::Conditional<atl::Array<float> >& diagScores
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Image on which object occurrence will be searched
➡	inSearchRegion	Optional<const ShapeRegion&>		NIL	Region of possible object centers
➡	inSearchRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
➡	inEdgeModel	const EdgeModel&			Model of objects to be searched
➡	inMinPyramidLevel	int	0 – 12	0	Defines the lowest pyramid level at which object position is still refined
➡	inMaxPyramidLevel	Optional<int>	0 – 12	3	Defines the total number of reduced resolution levels that can be used to speed up computations
➡	inEdgeThreshold	float	0.01 – ∞	10.0f	Minimum strength of edges used for matching with the model
➡	inEdgePolarityMode	EdgePolarityMode::Type		MatchStrictly	Defines how edges with reversed polarity will contribute to the object score
➡	inEdgeNoiseLevel	EdgeNoiseLevel::Type		High	Defines how much noise the object edges have
➡	inIgnoreBoundaryObjects	bool		False	Flag indicating whether objects crossing image boundary should be ignored or not
➡	inMinScore	float	0.0 – 1.0	0.7f	Minimum score of object candidates accepted at each pyramid level
⬅	outObject	Conditional<Object2D>&			Found object
⬅	outObjectEdges	Optional<Conditional<Array<Path>>&>		NIL	Model edges of the found object
⬅	outPyramidHeight	Optional<int&>		NIL	Highest pyramid level used to speed up computations
⬅	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region
🔍	diagEdgePyramid	Array<Image>&			Image edges used for matching at each pyramid level
🔍	diagMatchPyramid	Array<Image>&			Candidate object locations found at each pyramid level
🔍	diagScores	Conditional<Array<float> >&			Scores of the found object at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outObjectEdges**, **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inEdgeModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence.

In the **inImage** every pixel with gradient's magnitude at least **inEdgeThreshold** is considered an edge pixel. Only those are later used during the matching process. To establish the value of this threshold properly the **diagEdgePyramid** output which shows all the edges with sufficient gradient's magnitude may be used. If the **inEdgePolarityMode** parameter is set to Ignore, the object occurrences in the **inImage** image do not have necessarily to have the same contrast as the object in the model image.

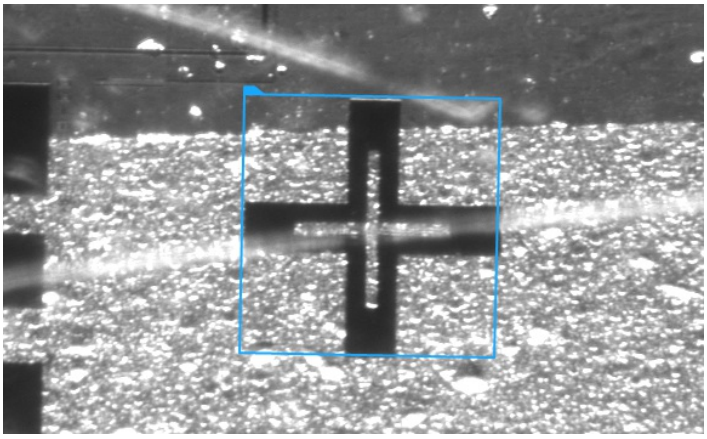
The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

The **outObject.Point** contains the model reference point of the matched object occurrence. The **outObject.Angle** contains the rotation angle of the object. The **outObject.Match** provides information about both the position and the angle of the found match combined into value of Rectangle2D type. The **outObject.Alignment** contains information about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of **outObject.Match** position. This value can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- You can use EnhanceSingleObjectMatch filter to fine-tune the results. A great example of usage is presented in the CreateGoldenTemplate2 filter.
- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision**, **inScalePrecision** and **inEdgeCompleteness**.
- To obtain high accuracy of matching make sure that the edges visible on the **diagEdgePyramid** output are not too thick. Increase **inEdgeThreshold** to make them thinner.
- Also consider increasing **inEdgeThreshold** if there is much noise on the **diagEdgePyramid** output.
- Verify accuracy of the matching by checking the **outObjectEdges** output. If the accuracy is lower than expected, make sure that **inMinPyramidLevel** = 0, try increasing **inEdgeThreshold** and also consider higher values for **inAnglePrecision** during model creation.
- To further improve matching accuracy use the EnhanceSingleObjectMatch filter.
- If the object being detected can be darker or brighter than the background on different images, use the **inEdgePolarityMode** parameter set to Ignore.
- If the object being detected is only partially visible or its shape and the model shape are not identical, use the **inEdgePolarityMode** parameter set to MatchWeakly.
- If there is only low noise in the object edges, use the **inEdgeNoiseLevel** parameter set to Low.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).

Examples



*Locating a single object with the edge-based method (**inMaxPyramidLevel** = 3). Background clutter and glares are efficiently ignored.*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Additional information about Template Matching can be found in Machine Vision Guide: Template Matching

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outObjectEdges**, **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inEdgeModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence.

In the **inImage** every pixel with gradient's magnitude at least **inEdgeThreshold** is considered an edge pixel. Only those are later used during the matching process. To establish the value of this threshold properly the **diagEdgePyramid** output which shows all the edges with sufficient gradient's magnitude may be used. If the **inEdgePolarityMode** parameter is set to Ignore, the object occurrences in the **inImage** image do not have necessarily to have the same contrast as the object in the model image.

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

The **outObject.Point** contains the model reference point of the matched object occurrence. The **outObject.Angle** contains the rotation angle of the object. The **outObject.Match** provides information about both the position and the angle of the found match combined into value of Rectangle2D type. The **outObject.Alignment** contains information about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of **outObject.Match** position. This value can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- You can use EnhanceSingleObjectMatch filter to fine-tune the results. A great example of usage is presented in the CreateGoldenTemplate2 filter.
- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**.

→	inMaxContrastRatio	Optional<float>	1.0 – ∞	NIL	Defines the maximal deviation of the brightness standard deviation of the model object and the object present in the image
←	outObject	Conditional<Object2D>&			Found object
←	outPyramidHeight	Optional<int&>		NIL	Highest pyramid level used to speed up computations
←	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region
🔍	diagImagePyramid	Array<Image>&			Pyramid of iteratively downsampled input image
🔍	diagMatchPyramid	Array<Image>&			Candidate object locations found at each pyramid level
🔍	diagScores	Conditional<Array<float> >&			Scores of the found object at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inGrayModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence.

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

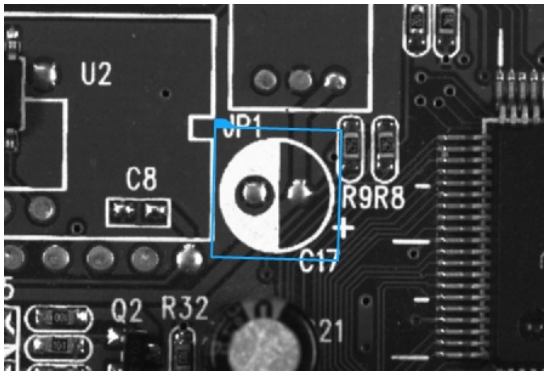
To be able to locate objects which are partially outside the image, the filter assumes that there are only black pixels beyond the image border.

The **outObject.Point** contains the model reference point of the matched object occurrence. The **outObject.Angle** contains the rotation angle of the object. The **outObject.Match** provides information about both the position and the angle of the found match combined into value of Rectangle2D type. The **outObject.Alignment** contains information about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of **outObject.Match** position. This value can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**. However, if you need to lower **inMinScore** below 0.5, then probably something else is wrong.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision** and **inScalePrecision**.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).
- Smoothing of the input image can significantly improve performance of this tool.

Examples



*Locating single object with the gray-based method (**inMaxPyramidLevel** = 4).*

🔍	diagScores	Conditional<Array<float>>&			Scores of the found object at each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inGrayModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMinScore** parameter determines the minimum score of the valid object occurrence.

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMinScore**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Larger **inMinScore** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

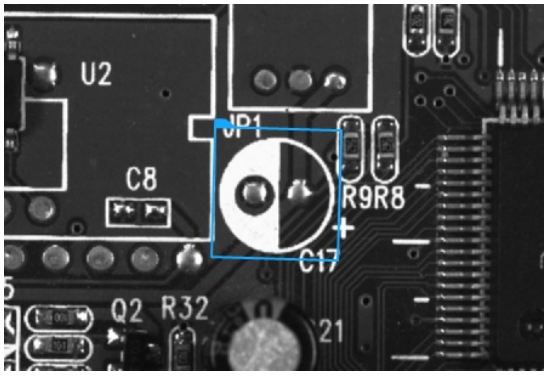
To be able to locate objects which are partially outside the image, the filter assumes that there are only black pixels beyond the image border.

The **outObject.Point** contains the model reference point of the matched object occurrence. The **outObject.Angle** contains the rotation angle of the object. The **outObject.Match** provides information about both the position and the angle of the found match combined into value of Rectangle2D type. The **outObject.Alignment** contains information about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of **outObject.Match** position. This value can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

Hints

- If an object is not detected, first try decreasing **inMaxPyramidLevel**, then try decreasing **inMinScore**. However, if you need to lower **inMinScore** below 0.5, then probably something else is wrong.
- If all the expected objects are correctly detected, try achieving higher performance by increasing **inMaxPyramidLevel** and **inMinScore**.
- Please note, that due to the pyramid strategy used for speeding-up computations, some objects whose score would finally be above **inMinScore** may be not found. This may be surprising, but this is by design. The reason is that the minimum value is used at different pyramid levels and many objects exhibit lower score at higher pyramid levels. They get discarded before they can be evaluated at the lowest pyramid level. Decrease **inMinScore** experimentally until all objects are found.
- If precision of matching is not very important, you can also gain some performance by increasing **inMinPyramidLevel**.
- If the performance is still not satisfactory, go back to model definition and try reducing the range of rotations and scaling as well as the precision-related parameters: **inAnglePrecision** and **inScalePrecision**.
- Define **inSearchRegion** to limit possible object locations and speed-up computations. Please note, that this is the region where the **outObject.Point** results belong to (and NOT the region within which the entire object has to be contained).
- Smoothing of the input image can significantly improve performance of this tool.

Examples



*Locating single object with the gray-based method (**inMaxPyramidLevel** = 4).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Additional information about Template Matching can be found in Machine Vision Guide: Template Matching

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid GrayModel2 in LocateSingleObject_NCC2. Create a proper model first using the Template Matching plugin or CreateGrayModel2 filter.

See Also

- LocateMultipleObjects_NCC2 – Finds all occurrences of a predefined template on an image by analysing the normalized correlation between pixel values.
- CreateGrayModel2 – Creates a model for NCC or SAD template matching.

LocateSingleObject_SAD

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Finds a single occurrence of a predefined template on an image by analysing the Square Average Difference between pixel values.

Applications: Almost always inferior to NCC, so rarely used in real applications.

Syntax

```
void avl::LocateSingleObject_SAD
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inSearchRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inSearchRegionAlignment,
 const avl::GrayModel& inGrayModel,
 int inMinPyramidLevel,
 atl::Optional<int> inMaxPyramidLevel,
 bool inIgnoreBoundaryObjects,
 float inMaxDifference,
 atl::Conditional<avl::Object2D>& outObject,
 atl::Optional<int&> outPyramidHeight = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedSearchRegion = atl::NIL,
 atl::Array<avl::Image>& diagImagePyramid,
 atl::Array<avl::Image>& diagMatchPyramid,
 atl::Conditional<atl::Array<float>>& diagScores
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image on which model occurrence will be searched
→	inSearchRegion	Optional<const ShapeRegion&>		NIL	Possible centers of the object occurrence
→	inSearchRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inGrayModel	const GrayModel&			Model which will be sought
→	inMinPyramidLevel	int	0 – 12	0	Defines the highest resolution level
→	inMaxPyramidLevel	Optional<int>	0 – 12	3	Defines the number of reduced resolution levels that can be used to speed up computations
→	inIgnoreBoundaryObjects	bool		False	Flag indicating whether objects crossing image boundary should be ignored or not
→	inMaxDifference	float	0.0 – ∞	0.0f	Maximum accepted average difference between pixel values
←	outObject	Conditional<Object2D>&			Found object
←	outPyramidHeight	Optional<int&>		NIL	Highest pyramid level used to speed up computations
←	outAlignedSearchRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region
🔍	diagImagePyramid	Array<Image>&			Pyramid of iteratively downsampled input image
🔍	diagMatchPyramid	Array<Image>&			Locations found on each pyramid level
🔍	diagScores	Conditional<Array<float>>&			Scores of found match on each pyramid level

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPyramidHeight**, **outAlignedSearchRegion**.

Read more about Optional Outputs.

Description

The operation matches the object model, **inGrayModel**, against the input image, **inImage**. The **inSearchRegion** region restricts the search area so that only in this region the centers of the objects can be presented. The **inMaxDifference** parameter determines the maximum average difference between corresponding pixel values of the valid object occurrence.

The computation time of the filter depends on the size of the model, the sizes of **inImage** and **inSearchRegion**, but also on the value of **inMaxDifference**. This parameter is a score threshold. Based on its value some partial computation can be sufficient to reject some locations as valid object instances. Moreover, the pyramid of the images is used. Thus, only the highest pyramid level is searched exhaustively, and potential candidates are later validated at lower levels. The **inMinPyramidLevel** parameter determines the lowest pyramid level used to validate such candidates. Setting this parameter to a value greater than 0 may speed up the computation significantly, especially for higher resolution images. However, the accuracy of the found object occurrences can be reduced. Lower **inMaxDifference** generates less potential candidates on the highest level to verify on lower levels. It should be noted that some valid occurrences with score above this score threshold can be missed. On higher levels score can be slightly lower than on lower levels. Thus, some valid object occurrences which on the lowest level would be deemed to be valid object instances can be incorrectly missed on some higher level. The **diagMatchPyramid** output represents all potential candidates recognized on each pyramid level and can be helpful during the difficult process of the proper parameter setting.

To be able to locate objects which are partially outside the image, the filter assumes that there are only black pixels beyond the image border.

The **outObject.Point** contains the model reference point of the matched object occurrence. The **outObject.Angle** contains the rotation angle of the object. The **outObject.Match** provides information about both the position and the angle of the found match combined into value of Rectangle2D type. The **outObject.Alignment** contains information about the transform required for geometrical objects defined in the context of template image to be transformed into object in the context of **outObject.Match** position. This value can be later used e.g. by 1D Edge Detection or Shape Fitting categories filters.

The SAD (Sum of Absolute Differences) method can be significantly slower than NCC (Normalized Cross-Correlation) method. Moreover, it is not illumination-invariant, as it is required in most applications. Thus, it is highly recommended to use the latter, NCC method instead.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Additional information about Template Matching can be found in Machine Vision Guide: Template Matching

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- LocateMultipleObjects_SAD - Finds multiple occurrences of a predefined template on an image by analysing the Square Average Difference between pixel values.

MergeMultipleLocationResults

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Combines results from multiple LocateMultipleObject instances.

Syntax

```
void avl::MergeMultipleLocationResults
(
 const atl::Array<avl::Object2D>& inObjects1,
 const atl::Array<avl::Object2D>& inObjects2,
 const atl::Array<avl::Object2D>& inObjects3,
 const atl::Array<avl::Object2D>& inObjects4,
 float inMinDistance,
 float inMinScore,
 atl::Array<avl::Object2D>& outObjects,
 atl::Array<int>& outIndices
)
```

Parameters

	Name	Type	Range	Default	Description
→	inObjects1	const Array<Object2D>&			
→	inObjects2	const Array<Object2D>&			
→	inObjects3	const Array<Object2D>&			
→	inObjects4	const Array<Object2D>&			
→	inMinDistance	float	0.0 - ∞	10.0f	
→	inMinScore	float	-1.0 - 1.0	0.0f	
←	outObjects	Array<Object2D>&			
←	outIndices	Array<int>&			

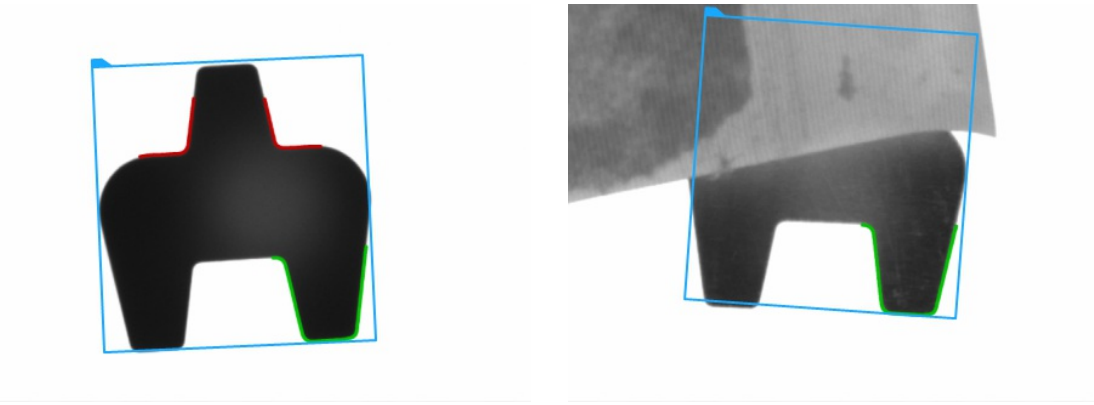
Description

Filter selects the best matching object from the given matching objects.

This filter is especially useful for finding big objects by using smaller template models instead of the large model.

This filter will return a valid object location even if object is partially covered.

Examples



Object location found based on two matching objects(red and green).

Remarks

Each template matching object which is used in filter must have set this same **reference frame**.

See Also

- LocateMultipleObjects_Edges1 – Finds all occurrences of a predefined template on an image by comparing object edges.
- LocateSingleObject_Edges1 – Finds a single occurrence of a predefined template on an image by comparing object edges.

MergeSingleLocationResults

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Combines results from multiple LocateSingleObject instances.

Syntax

```
void avl::MergeSingleLocationResults
(
 const atl::Conditional<avl::Object2D>& inObject1,
 const atl::Conditional<avl::Object2D>& inObject2,
 const atl::Conditional<avl::Object2D>& inObject3,
 const atl::Conditional<avl::Object2D>& inObject4,
 float inMinScore,
 atl::Conditional<avl::Object2D>& outObject,
 atl::Conditional<int>& outIndex
)
```

Parameters

	Name	Type	Range	Default	Description
→	inObject1	const Conditional<Object2D>&			
→	inObject2	const Conditional<Object2D>&			
→	inObject3	const Conditional<Object2D>&			
→	inObject4	const Conditional<Object2D>&			
→	inMinScore	float	-1.0 – 1.0	0.0f	
←	outObject	Conditional<Object2D>&			
←	outIndex	Conditional<int>&			

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inObject1** and **outObject**, **inObject2** and **outObject**, **inObject3** and **outObject**, **inObject4** and **outObject**

Read more about In-place Computation.

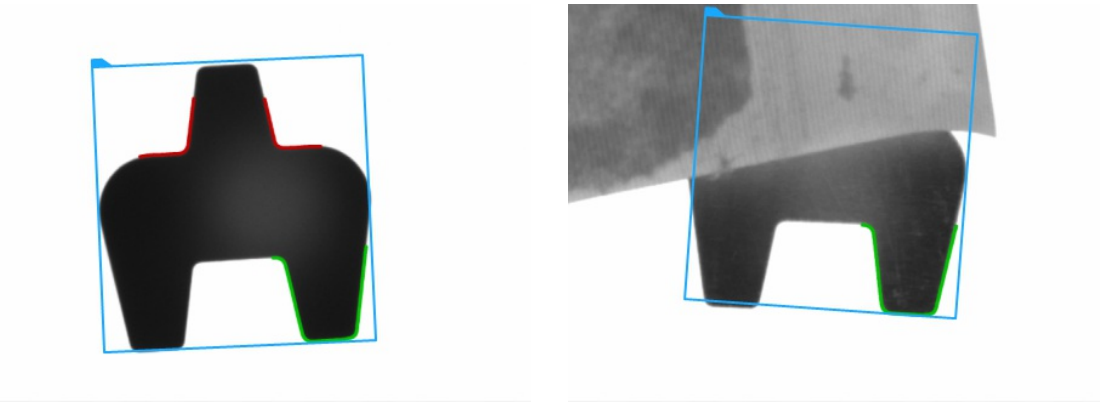
Description

Filter selects the best matching object from the given matching objects.

This filter is especially useful for finding big objects by using smaller template models instead of the large model.

This filter will return a valid object location even if object is partially covered.

Examples



Object location found based on two matching objects(red and green).

Remarks

Each template matching object which is used in filter must have set this same **reference frame**.

- LocateMultipleObjects_Edges1 – Finds all occurrences of a predefined template on an image by comparing object edges.
- LocateSingleObject_Edges1 – Finds a single occurrence of a predefined template on an image by comparing object edges.

SaveEdgeModel

Header: AVL.h
Namespace: avl
Module: MatchingPro

Saves serialized template matching EdgeModel object as AVDATA file.

Syntax

```
void avl::SaveEdgeModel
(
 const avl::EdgeModel& inEdgeModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inEdgeModel	const EdgeModel&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SaveEdgeModel2

Header: AVL.h
Namespace: avl
Module: MatchingPro

Saves serialized template matching EdgeModel2 object as AVDATA file.

Syntax

```
void avl::SaveEdgeModel2
(
 const avl::EdgeModel2& inEdgeModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inEdgeModel	const EdgeModel2&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SaveGrayModel

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Saves serialized template matching GrayModel object as AVDATA file.

Syntax

```
void avl::SaveGrayModel
(
 const avl::GrayModel& inGrayModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inGrayModel	const GrayModel&		Model to be serialized
➡	inFilename	const File&		Name of the target file

SaveGrayModel2

Header: AVL.h
Namespace: avl
Module: MatchingBasic

Saves serialized template matching GrayModel2 object as AVDATA file.

Syntax

```
void avl::SaveGrayModel2
(
 const avl::GrayModel2& inGrayModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inGrayModel	const GrayModel2&		Model to be serialized
➡	inFilename	const File&		Name of the target file

CheckPresence_EdgeAmount

Header: AVL.h
Namespace: avl
Module: FoundationPro

Verifies object presence by analysing the amount of edges in the specified region.

Applications: Quick and easy presence verification, e.g. for missing caps, screws, labels.

Syntax

```
void avl::CheckPresence_EdgeAmount
(
 const avl::Image& inImage,
 const avl::ShapeRegion& inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 avl::GradientMaskOperator::Type inEdgeOperator,
 avl::MagnitudeMeasure::Type inEdgeMeasure,
 const int inEdgeScale,
 int inMinStrength,
 float inMinAmount,
 float inMaxAmount,
 bool& outIsPresent,
 atl::Optional<float&> outAmount = atl::NIL,
 atl::Optional<avl::Region&> outForeground = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedRoi = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	const ShapeRegion&			Location at which object presence is being checked
→	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inEdgeOperator	GradientMaskOperator::Type			Selected gradient operator
→	inEdgeMeasure	MagnitudeMeasure::Type		Sum	Selected method of gradient magnitude computation
→	inEdgeScale	const int	1 – 16	1	Scales the resulting gradient magnitudes
→	inMinStrength	int	0 – 255	15	Lowest acceptable edge magnitude
→	inMinAmount	float	0.0 – 1.0	0.2f	Lowest acceptable fraction of pixels meeting the criteria
→	inMaxAmount	float	0.0 – 1.0	1.0f	Highest acceptable fraction of pixels meeting the criteria
←	outIsPresent	bool&			Flag indicating whether the object is present or not
←	outAmount	Optional<float&>		NIL	Fraction of pixels from meeting the criteria
←	outForeground	Optional<Region&>		NIL	Region of pixels meeting the criteria
←	outAlignedRoi	Optional<ShapeRegion&>		NIL	Input ROI after transformation (in the image coordinates)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAmount**, **outForeground**, **outAlignedRoi**.

Read more about Optional Outputs.

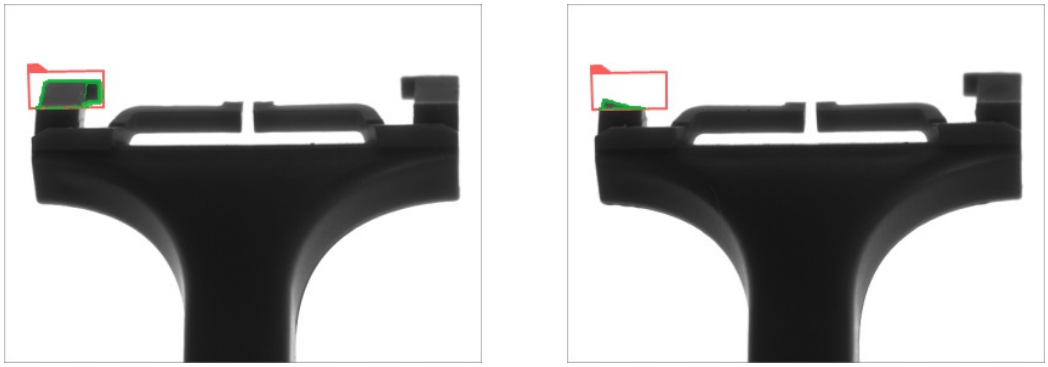
Description

The filter extracts foreground pixels and checks if their number comparing to the area of the whole ROI fits the range (**inMinAmount**, **inMaxAmount**). The pixel is considered a foreground pixel if and only if its gradient magnitude is at least **inMinStrength**.

Hints

- If the object location is variable, Pass an appropriate local coordinate system to **inRoiAlignment**.
- Define **inRoi** to specify the image location at which the object presence will be checked.
- Set **inMinStrength** to a value that results in good edges visible on the **outForeground** output.
- Investigate the values that appear on the **outAmount** output, then set **inMinAmount** and **inMaxAmount** to values appropriate for correct objects.
- When creating data previews, use **outAlignedRoi** and NOT **inRoi** as only the former will be properly aligned to the object location.

Examples



*CheckPresence_EdgeAmount performed on sample images with **inMinAmount** = 0.2. In the left image the object is present, while in the right image it is not. Green pixels are foreground pixels.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CheckPresence_EdgeAmount.

See Also

- CheckPresence_Intensity – Verifies object presence by analysing pixel intensities in the specified region.
- CheckPresence_EdgeAmount – Verifies object presence by analysing the amount of edges in the specified region.
- ThresholdToRegion_HSx – Creates a region containing image pixels which belongs to specified region in HSV, HSL or HSI space.
- ThresholdToRegion – Creates a region containing image pixels with values within the specified range.

CheckPresence_Intensity

Header: AVL.h
Namespace: avl
Module: FoundationPro

Verifies object presence by analysing pixel intensities in the specified region.

Applications: Quick and easy presence verification, e.g. for missing caps, screws, labels.

Syntax

```
void avl::CheckPresence_Intensity
(
 const avl::Image& inImage,
 const avl::ShapeRegion& inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 atl::Optional<float> inMinIntensity,
 atl::Optional<float> inMaxIntensity,
 float inMinContrast,
 atl::Optional<float> inMaxContrast,
 bool& outIsPresent,
 atl::Optional<float&> outIntensity = atl::NIL,
 atl::Optional<float&> outContrast = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedRoi = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	const ShapeRegion&			Location at which object presence is being checked
→	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inMinIntensity	Optional<float>		NIL	Lowest acceptable value for the average pixel value
→	inMaxIntensity	Optional<float>		NIL	Highest acceptable value for the average pixel value
→	inMinContrast	float	0.0 – ∞		Lowest acceptable value for the standard deviation of the pixel values
→	inMaxContrast	Optional<float>	0.0 – ∞	NIL	Highest acceptable value for the standard deviation of the pixel values
←	outIsPresent	bool&			Flag indicating whether the object is present or not
←	outIntensity	Optional<float&>		NIL	Average pixel value
←	outContrast	Optional<float&>		NIL	Standard deviation of the pixel values
←	outAlignedRoi	Optional<ShapeRegion&>		NIL	Input ROI after transformation (in the image coordinates)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIntensity**, **outContrast**, **outAlignedRoi**.

Read more about Optional Outputs.

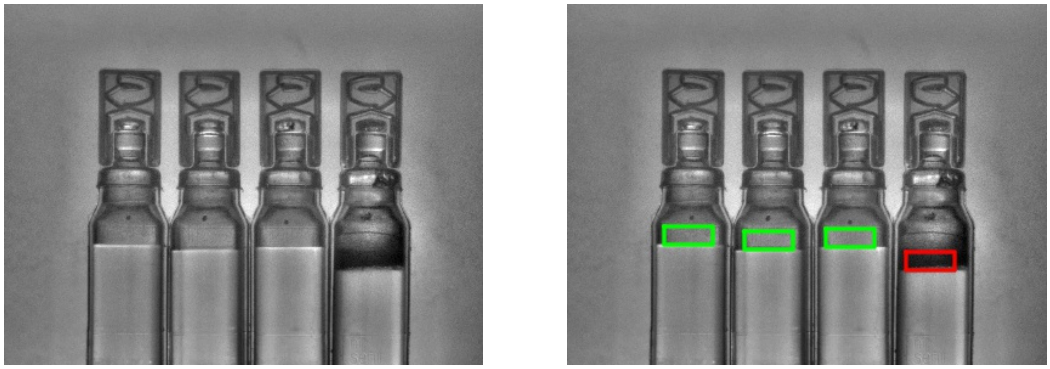
Description

The filter computes basic statistics of the image pixels in selected ROI and checks if they fit the defined ranges. The used statistics are average and standard deviation of the pixel values.

Hints

- If the object location is variable, Pass an appropriate local coordinate system to **inRoiAlignment**.
- Define **inRoi** to specify the image location at which the object presence will be checked.
- Investigate the values that appear on **outIntensity** and **outContrast** outputs. With this information set **inMinIntensity**, **inMaxIntensity**, **inMinContrast** and **inMaxContrast** to values which are appropriate for correct objects.
- When creating data previews, use **outAlignedRoi** and NOT **inRoi** as only the former will be properly aligned to the object location.

Examples



*CheckPresence_Intensity performed on sample image with **inMinIntensity** = 80. The foam is present in red rectangle.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CheckPresence_Intensity.

See Also

- CheckPresence_PixelAmount – Verifies object presence by analysing the amount of pixels that meet the specified criteria.
- CheckPresence_EdgeAmount – Verifies object presence by analysing the amount of edges in the specified region.
- ImageAverage – Computes the average of the image pixel values.

CheckPresence_PixelAmount

Header: AVL.h
Namespace: avl
Module: FoundationPro

Verifies object presence by analysing the amount of pixels that meet the specified criteria.

Applications: Quick and easy presence verification, e.g. for missing caps, screws, labels.

Syntax

```
void avl::CheckPresence_PixelAmount
(
 const avl::Image& inImage,
 const avl::ShapeRegion& inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 avl::HSxColorModel::Type inColorModel,
 int inBeginHue,
 int inEndHue,
 int inMinSaturation,
 atl::Optional<int> inMaxSaturation,
 atl::Optional<float> inMinBrightness,
 atl::Optional<float> inMaxBrightness,
 float inMinAmount,
 float inMaxAmount,
 bool& outIsPresent,
 atl::Optional<float&> outAmount = atl::NIL,
 atl::Optional<avl::Region&> outForeground = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedRoi = atl::NIL,
 avl::Image& diagHsxImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	const ShapeRegion&			Location at which object presence is being checked
→	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inColorModel	HSxColorModel::Type			Selected color model
→	inBeginHue	int	0 – 255	0	Begin of the range of acceptable hue
→	inEndHue	int	0 – 255	255	End of the range of acceptable hue
→	inMinSaturation	int	0 – 255	128	Lowest acceptable saturation
→	inMaxSaturation	Optional<int>	0 – 255	NIL	Highest acceptable saturation
→	inMinBrightness	Optional<float>	0.0 – ∞	128.0f	Lowest acceptable brightness
→	inMaxBrightness	Optional<float>	0.0 – ∞	NIL	Highest acceptable brightness
→	inMinAmount	float	0.0 – 1.0	0.5f	Lowest acceptable fraction of pixels meeting the criteria
→	inMaxAmount	float	0.0 – 1.0	1.0f	Highest acceptable fraction of pixels meeting the criteria
←	outIsPresent	bool&			Flag indicating whether the object is present or not
←	outAmount	Optional<float&>		NIL	Fraction of pixels meeting the criteria
←	outForeground	Optional<Region&>		NIL	Region of pixels meeting the criteria
←	outAlignedRoi	Optional<ShapeRegion&>		NIL	Input ROI after transformation (in the image coordinates)
🔍	diagHsxImage	Image&			Image represented in chosen color model

Requirements

For input **inImage** only pixel formats are supported: 3×uint8, 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAmount**, **outForeground**, **outAlignedRoi**.

Read more about Optional Outputs.

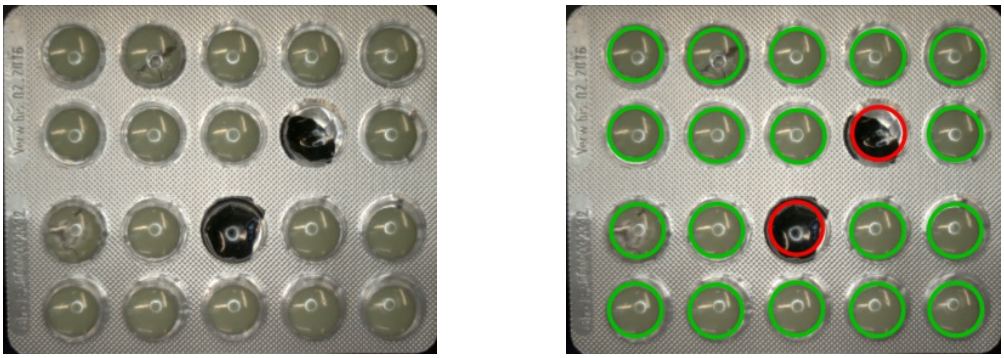
Description

The filter extracts foreground pixels by means of image thresholding and checks if their number comparing to the area of the whole ROI fits the range (**inMinAmount**, **inMaxAmount**). If the input image has 3 channels, the ThresholdToRegion_HSx filter is used for thresholding, and if the image has 1 channel (i.e. it is monochromatic), the simple ThresholdToRegion filter is performed. In the latter case only **inMinBrightness** and **inMaxBrightness** parameters matter.

Hints

- If the object location is variable, Pass an appropriate local coordinate system to **inRoiAlignment**.
- Define **inRoi** to specify the image location at which the object presence will be checked.
- Set **inBeginHue** and **inEndHue** to values appropriate for correct objects.
- Limit the ranges of **inMinSaturation**–**inMaxSaturation** and **inMinBrightness**–**inMaxBrightness**.
- Verify that the **outForeground** output represents pixels belonging to correct objects.
- Investigate the values that appear on the **outAmount** output, then set **inMinAmount** and **inMaxAmount** to values appropriate for correct objects.
- When creating data previews, use **outAlignedRoi** and NOT **inRoi** as only the former will be properly aligned to the object location.

Examples



*CheckPresence_PixelAmount performed on sample image with **inMinAmount** = 0.7. The defects are present in red circles.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect inMaxBrightness value in CheckPresence_PixelAmount.
DomainError	Incorrect inMinBrightness value in CheckPresence_PixelAmount.
DomainError	Region exceeds an input image in CheckPresence_PixelAmount.
DomainError	Not supported inImage pixel format in CheckPresence_PixelAmount. Supported formats: 3xUInt8, 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

See Also

- CheckPresence_Intensity – Verifies object presence by analysing pixel intensities in the specified region.
- CheckPresence_EdgeAmount – Verifies object presence by analysing the amount of edges in the specified region.
- ThresholdToRegion_HSx – Creates a region containing image pixels which belongs to specified region in HSV, HSL or HSI space.
- ThresholdToRegion – Creates a region containing image pixels with values within the specified range.

CompareGoldenTemplate2

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares an image with a multi-image model using an ensemble of image features approach.

Applications: Finding general object defects by analyzing brightness deviations from a template image.

Syntax

```
void avl::CompareGoldenTemplate2
(
 const avl::Image& inImage,
 const avl::GoldenTemplate2Model& inModel,
 float inSensitivityA,
 float inSensitivityB,
 avl::Region& outDefects
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inModel	const GoldenTemplate2Model&			
→	inSensitivityA	float	0.0 – ∞	1.0f	Usually influences small, distinctive defects.
→	inSensitivityB	float	0.0 – ∞	0.95f	Usually influences bigger, extensive defects.
←	outDefects	Region&			

Description

This filter compares pixels of the input images against a template created by CreateGoldenTemplate2 and creates a region containing only pixels that are different.

The filter expects the object to be positioned precisely and in the same way as object images used to construct the **inModel** – see CreateGoldenTemplate2.

Sensitivity of the filter can be adjusted using **inSensitivityA** and **inSensitivityB** parameters.

See Also

- CreateGoldenTemplate2 – Create a model to be used with CompareGoldenTemplate2 filter.

CompareGoldenTemplate_Edges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares image edges with the edges of a perfect template. Significant differences are considered defects.

Applications: Finding general object defects by analyzing missing or excessive edges.

Syntax

```
void avl::CompareGoldenTemplate_Edges
(
 const avl::Image& inImage,
 const avl::EdgeGoldenTemplate& inGoldenTemplate,
 const avl::CoordinateSystem2D& inGoldenTemplateAlignment,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 int inMaxDistance,
 avl::Region& outDefects,
 bool& outDefectsPresent,
 avl::Region& outMissingEdges,
 avl::Region& outExcessiveEdges,
 atl::Optional<avl::Region&> outImageEdges = atl::NIL,
 atl::Optional<avl::Region&> outGoldenEdges = atl::NIL,
 atl::Optional<avl::Region&> outMatchingEdges = atl::NIL,
 atl::Optional<avl::Rectangle2D&> outObjectPosition = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inGoldenTemplate	const EdgeGoldenTemplate&			Golden edge template containing image with no defects
→	inGoldenTemplateAlignment	const CoordinateSystem2D&			Adjusts the golden template to the position of the inspected object
→	inStdDevX	float	0.0 – ∞	2.0f	Amount of horizontal smoothing used by the edge filter
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Amount of vertical smoothing used by the edge filter (Auto = inStdDevX)
→	inEdgeThreshold	float	0.0 – ∞	35.0f	Sufficient edge strength; edges of that strength will always be detected on the input image
→	inEdgeHysteresis	float	0.0 – ∞	15.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxDistance	int	0 – ∞	3	Maximal allowed distance between corresponding edges on the input and golden image
←	outDefects	Region&			Region of detected defects
←	outDefectsPresent	bool&			Flag indicating whether any defects were detected
←	outMissingEdges	Region&			Edges present on the golden image that are missing on the input image
←	outExcessiveEdges	Region&			Edges that are not present on the golden image
←	outImageEdges	Optional<Region&>		NIL	Edges on the input image
←	outGoldenEdges	Optional<Region&>		NIL	Edges on the golden image
←	outMatchingEdges	Optional<Region&>		NIL	Golden edges present on the input image
←	outObjectPosition	Optional<Rectangle2D&>		NIL	Position of the object being compared

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outImageEdges**, **outGoldenEdges**, **outMatchingEdges**, **outObjectPosition**.

Read more about Optional Outputs.

Description

This filter compares edges given input image with an image stored in a golden template and then, as a result, creates a region containing only pixels where edges are different.

This method is especially useful for finding defects of the object shape. Due to invulnerability to color changes, it may be used in appliances with changing light conditions.

Parameter **inMaxDistance** defines the maximal distances of two edges that should be treated as the same edge.

To prepare image and area to be compared in it you can use CreateGoldenTemplate_Edges filter or property window.

Mostly the **inEdgeThreshold** and **inEdgeHysteresis** parameters should have the same value as in CreateGoldenTemplate_Edges filter. The values should be changed however if the brightness of the input image is significantly different from the brightness of the golden image used in CreateGoldenTemplate_Edges. The **inEdgeThreshold** can be also decreased slightly if one wants to concentrate on missing edges or increased to concentrate on excessive edges.

More information about this technique can be found in Machine Vision Guide: Golden Template.

Hints

- A golden template comparison filter should be preceded with filters finding the object in certain location. Most typically we do this with LocateSingleObject_Edges1 filter.
- Connect the **inImage** input with the image containing the object.
- Select an image with a perfect object and use it to create golden template using the CreateGoldenTemplate_Edges filter.
- Set **inEdgeThreshold**, **inEdgeHysteresis**, **inStdDevX** and **inStdDevY** as in DetectEdges_AsRegion filter. These will control detection of the edges used for object comparison.
- Set **inMaxDistance** to specify the maximum spatial deviation between the edges on the input image and the edges on the template.

Remarks

Due to performance, it is recommended to create a template using the CreateGoldenTemplate_Edges filter outside a main loop of a program. It will create a model only once, instead of each iteration.

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid golden template on input in CompareGoldenTemplate_Edges.

See Also

- CreateGoldenTemplate_Intensity – Creates golden template for application in CompareGoldenTemplate_Intensity filter.
- CompareGoldenTemplate_Intensity – Compares an image with a template image considered to have no defects.

CompareGoldenTemplate_Intensity

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares an image with a template image considered to have no defects.

Applications: Finding general object defects by analyzing brightness deviations from a template image.

Syntax

```
void avl::CompareGoldenTemplate_Intensity
(
 const avl::Image& inImage,
 const avl::GrayGoldenTemplate& inGoldenTemplate,
 atl::Optional<const avl::CoordinateSystem2D&> inGoldenTemplateAlignment,
 float inMaxDifference,
 int inMinDefectRadius,
 avl::Region& outDefects,
 avl::Region& outDifferenceRegion,
 bool& outDefectsPresent,
 avl::Region& outEdgeRegion,
 atl::Optional<avl::Rectangle2D&> outObjectPosition = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inGoldenTemplate	const GrayGoldenTemplate&			Golden gray template containing image of an object with no defects
→	inGoldenTemplateAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the golden template to the position of the inspected object
→	inMaxDifference	float	0.0 – ∞	20.0f	Maximal allowed difference between corresponding pixels of the input and golden images
→	inMinDefectRadius	int	0 – ∞	1	Minimal radius of a defect
←	outDefects	Region&			Region of detected defects
←	outDifferenceRegion	Region&			Region of pixels differing too much between the golden image and the input image
←	outDefectsPresent	bool&			Flag indicating whether any defects were detected
←	outEdgeRegion	Region&			Region of pixels that will not be compared
←	outObjectPosition	Optional<Rectangle2D&>		NIL	Position of the object being compared

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outObjectPosition**.

Read more about Optional Outputs.

Description

This filter compares pixels of the input images against a template image stored in passed **inGoldenTemplate** input. Then creates a region containing only pixels in which intensity difference is higher than **inMaxDifference** value as a result. This method is especially useful for finding defects like: smudges, noises and dust particles. It can be used for finding missing holes or changes in complex shapes.

When the defected pixels are found only consistent regions are selected. Minimal radius of accepted region is set in **inMinDefectRadius**.

You can define a part of an image when defining **inGoldenTemplate**.

More information about this technique can be found in Machine Vision Guide: Golden Template.

Hints

- A golden template comparison filter should be preceded with filters finding the object in certain location. Most typically we do this with LocateSingleObject_Edges1 filter.
- Connect the **inImage** input with the image containing the object.
- Select an image with a perfect object and use it to create golden template using the CreateGoldenTemplate_Intensity filter.
- Set **inMaxDifference** to a value that assures detection of all true defects and no false ones. Verify this with the **outDefects** output.
- Dismiss very small defects by setting **inMinDefectRadius**.

Examples

CompareGoldenTemplate_Intensity performed on sample image. A part of the object is missing – it is marked in blue on the right.

Remarks

Due to performance, it is recommended to create a template using the CreateGoldenTemplate_Intensity filter outside a main loop of a program. It will create a model only once, instead of each iteration.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input image format is incompatible with golden template image format in CompareGoldenTemplate_Intensity.
DomainError	No valid golden template on input in CompareGoldenTemplate_Intensity.

See Also

- CompareGoldenTemplate_Edges – Compares image edges with the edges of a perfect template. Significant differences are considered defects.
- CreateGoldenTemplate_Intensity – Creates golden template for application in CompareGoldenTemplate_Intensity filter.

CreateGoldenTemplate2

Header: AVL.h
Namespace: avl
Module: FoundationPro

Create a model to be used with CompareGoldenTemplate2 filter.

Syntax

```
void avl::CreateGoldenTemplate2
(
 const atl::Array<avl::Image>& inImages,
 const atl::Optional<const avl::Region&>& inObjectMask,
 int inDownscale,
 int inMaxDisplacement,
 int inLargeDefectSize,
 int inBrightnessAugmentation,
 int inNoiseAugmentation,
 float inSmoothingAugmentationStdDev,
 avl::GoldenTemplate2Model& outModel
)
```

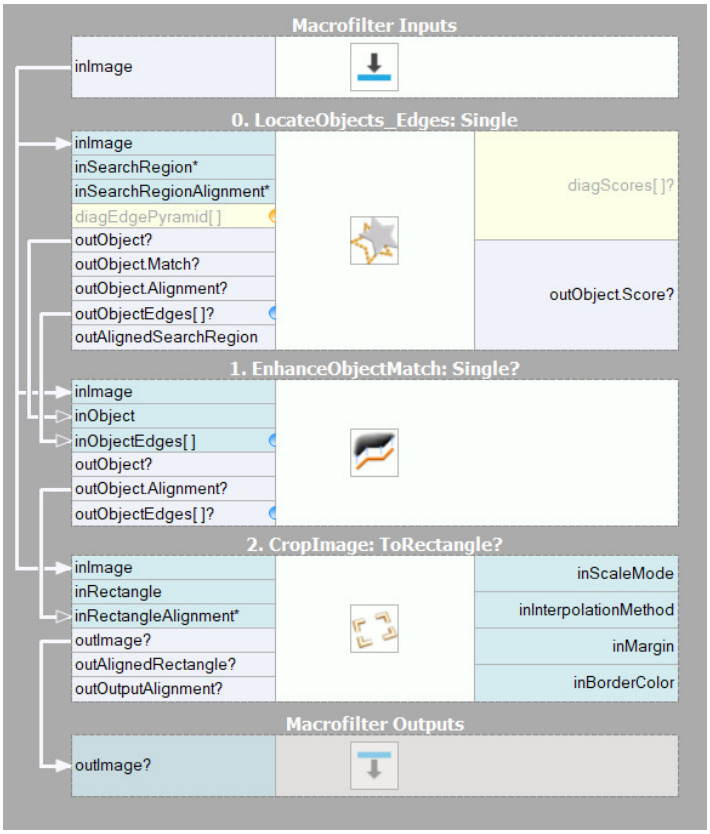
Parameters

	Name	Type	Range	Default	Description
→	inImages	const Array<Image>&			List of input images that has to be uniform in terms of size and format.
→	inObjectMask	const Optional<const Region&>&		NIL	
→	inDownscale	int	1 – ∞	2	Shrink the input for processing by dividing by specified value. Reduces sensitivity to minuscule (pixel-size) defects. Greatly improves processing speed.
→	inMaxDisplacement	int	0 – ∞	2	Error in object positioning. If in doubt, it is better to set this value too high. If set too low, subtle defects won't be detected, or no defects may not be detected at all. High values may impair detection of small defects, especially near edges.
→	inLargeDefectSize	int	0 – ∞	50	Expected size (diameter) of largest, extensive defects.
→	inBrightnessAugmentation	int		0	Allows for greater (additional to the value inferred from inImages training set) brightness deviation in inspected images.
→	inNoiseAugmentation	int		0	Allows for greater (additional to the value inferred from inImages training set) noise presence in inspected images. Uses a uniform noise with specified distribution width.
→	inSmoothingAugmentationStdDev	float	0.0 – ∞	0.0f	Allows for greater (additional to the value inferred from inImages training set) image smoothing in inspected images. Uses gaussian smoothing with specified standard deviation.
←	outModel	GoldenTemplate2Model&			

Description

This filter creates a template that can be later used in CompareGoldenTemplate2 filter.

Multiple images (at least 3, however it is recommended to use at least 5) of inspected object are required to properly create the model. Also, the filter expects the object to be positioned precisely. The positioning of inspected object can be achieved in Aurora Vision Studio by using following filter sequence.



Please note, that it is recommended to enable the scale adjustment in EnhanceSingleObjectMatch filter, as all input images for Golden Template model creation need to have the same dimensions.

The CreateGoldenTemplate2 filter also requires an object mask - pixels outside this mask won't be taken into consideration, however when object is visible against an uniform and constant background it is recommended to include some of the background in order to improve defect detection near the object edges.

It is important to set the **inMaxDisplacement** parameter properly, which describes the object positioning error, in pixels. If it is set too low, subtle defects won't be detected, or no defects may not be detected at all. On the other hand, high values may impair detection of small defects, especially near edges.

The **augmentation** could be used when it is known that images subjected to inspection will be different in *some specific manner* from the training image set. Namely, **inBrightnessAugmentation** is to be used when inspected images could differ in brightness from the training set, **inNoiseAugmentation** - for noise content difference and **inSmoothingAugmentationStdDev** - when inspected images could be blurred w.r.t the training set. Note, that it is always better to obtain a representative training set than to use augmentation parameters. Also note, that the overall sensitivity of the defect detection is governed by CompareGoldenTemplate2 filter sensitivity parameters.

Errors

List of possible exceptions:

Error type	Description
DomainError	inImages - inObjectMask dimensions differ in CreateGoldenTemplate2.
DomainError	inImages array must contain at least 3 different images of the object, 5 is recommended in CreateGoldenTemplate2
DomainError	Input image dimensions differ in CreateGoldenTemplate2.
DomainError	Input image formats differ in CreateGoldenTemplate2.

CreateGoldenTemplate_Edges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates golden template for application in CompareGoldenTemplate_Edges filter.

Syntax

```
void avl::CreateGoldenTemplate_Edges
(
 const avl::Image& inTemplateImage,
 atl::Optional<const avl::Rectangle2D&> inTemplateArea,
 atl::Optional<const avl::Region&> inMask,
 atl::Optional<const avl::CoordinateSystem2D&> inTemplateAreaAlignment,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 avl::EdgeGoldenTemplate& outGoldenTemplate,
 avl::Image& diagCroppedImage,
 avl::Region& diagCroppedEdges,
 avl::Region& diagEdges
)
```

Parameters

	Name	Type	Range	Default	Description
→	inTemplateImage	const Image&			Template image containing an object with no defects
→	inTemplateArea	Optional<const Rectangle2D&>		NIL	Desired area to compare
→	inMask	Optional<const Region&>		NIL	Range of pixels to compare
→	inTemplateAreaAlignment	Optional<const CoordinateSystem2D&>		NIL	Alignment of template bounded by inTemplateArea
→	inStdDevX	float	0.0 – ∞	2.0f	Amount of horizontal smoothing used by the edge filter
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Amount of vertical smoothing used by the edge filter (Auto = inStdDevX)
→	inEdgeThreshold	float	0.0 – ∞	35.0f	Sufficient edge strength; edges of that strength will always be detected on the template image
→	inEdgeHysteresis	float	0.0 – ∞	15.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
←	outGoldenTemplate	EdgeGoldenTemplate&			The output golden template structure
🔍	diagCroppedImage	Image&			Cropped image to be analyzed
🔍	diagCroppedEdges	Region&			Edges found on the cropped image
🔍	diagEdges	Region&			Edges projected onto the input image

Description

This filter creates a template structure that can be later used in CompareGoldenTemplate_Edges filter.

This method is especially useful for finding defects of the object shape. Due to invulnerability to color changes, it may be used in appliances with changing light conditions.

More information about this technique can be found in Machine Vision Guide: Golden Template.

Hints

- A golden template comparison filter should be preceded with filters finding the object in certain location. Most typically we do this with LocateSingleObject_Edges1 filter.
- Connect the **inTemplateImage** input with the image containing the perfect object.
- Set **inEdgeThreshold**, **inEdgeHysteresis**, **inStdDevX** and **inStdDevY** as in DetectEdges_AsRegion filter. These will control detection of the edges used for object comparison.

Remarks

Due to performance, it is recommended to create a template outside a main loop of a program. It will create a model only once, instead of each iteration.

CreateGoldenTemplate_Intensity

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates golden template for application in CompareGoldenTemplate_Intensity filter.

Syntax

```
void avl::CreateGoldenTemplate_Intensity
(
 const avl::Image& inTemplateImage,
 atl::Optional<const avl::Rectangle2D&> inTemplateArea,
 atl::Optional<const avl::Region&> inMask,
 atl::Optional<const avl::CoordinateSystem2D&> inTemplateAreaAlignment,
 const float inEdgeThreshold,
 const int inEdgeDilation,
 avl::GrayGoldenTemplate& outGoldenTemplate,
 avl::Image& diagCroppedImage,
 avl::Region& diagCroppedEdgeRegion,
 avl::Region& diagEdgeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inTemplateImage	const Image&			Template image containing an object with no defects
→	inTemplateArea	Optional<const Rectangle2D&>		NIL	Desired area to compare
→	inMask	Optional<const Region&>		NIL	Range of pixels to compare
→	inTemplateAreaAlignment	Optional<const CoordinateSystem2D&>		NIL	Alignment of template bounded by inTemplateArea
→	inEdgeThreshold	const float	0.0 – ∞	10.0f	Minimum strength of edges on the golden image near which comparison is NOT performed
→	inEdgeDilation	const int	0 – 1000000	1	Defines for how far from the detected edges comparison is NOT performed
←	outGoldenTemplate	GrayGoldenTemplate&			The output golden template structure
🔍	diagCroppedImage	Image&			Cropped image to be analyzed
🔍	diagCroppedEdgeRegion	Region&			Region of pixels that will not be compared
🔍	diagEdgeRegion	Region&			Edges projected onto the input image

Description

This filter creates a template structure that can be later used in CompareGoldenTemplate_Intensity filter. This golden template method is especially useful for finding defects like: smudges, noises and dust particles. It can be used for finding missing holes or changes in complex shapes.

Filter finds edges on an image and removes nearby pixels to avoid comparing pixels near edges which may contains some distortions due to shadows or changes in lightning. Input **inEdgeDilation** defines the width of the quiet zone around the edges and the parameter **inEdgeThreshold** define how strong must be change of the color between pixels to treat them as an edge.

More information about this technique can be found in Machine Vision Guide: Golden Template.

Hints

- A golden template comparison filter should be preceded with filters finding the object in certain location. Most typically we do this with LocateSingleObject_Edges1 filter.
- Connect the **inTemplateImage** input with the image containing the perfect object.
- Set **inEdgeThreshold** to a value that assures detection of all object edges, so that defects appearing near the edges can be ignored. Verify this setting with the **diagEdgeRegion** output – it should be present near the edges.

Remarks

Due to performance, it is recommended to create a template outside a main loop of a program. It will create a model only once, instead of each iteration.

CreateMeasurementMap

Header: AVL.h
Namespace: avl
Module: FoundationPro

(Pre)computes image sampling locations used by MeasureObjectWidth function.

Syntax

```
void avl::CreateMeasurementMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::SegmentScanField& inScanField,
 atl::Optional<const avl::CoordinateSystem2D&> inScanFieldAlignment,
 int inScanCount,
 int inScanWidth,
 avl::InterpolationMethod::Type inImageInterpolation,
 atl::Array<avl::ScanMap>& outMeasurementMap,
 atl::Optional<avl::SegmentScanField&> outAlignedScanField = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Information about dimensions, depth and pixel type of the scan image
→	inScanField	const SegmentScanField&			Field in which scans will be performed
→	inScanFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan field to the position of the inspected object
→	inScanCount	int	2 – ∞	5	Number of scans to be performed
→	inScanWidth	int	1 – ∞	5	Width of the scan area
→	inImageInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used in extraction of image pixel values
←	outMeasurementMap	Array<ScanMap>&			
←	outAlignedScanField	Optional<SegmentScanField&>		NIL	Field in which the scans will be performed
🔍	diagScanSegments	Array<Segment2D>&			Array of scan segments

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanField**.

Read more about Optional Outputs.

DetectCorners_CornerResponse

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Detects corners using corner response method.

Applications: Detection of characteristic points on an image.

Syntax

```
void avl::DetectCorners_CornerResponse
(
 const avl::Image& inMonoImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::CornerResponseMethod::Type inCornerResponseMethod,
 const int inKernelSize,
 atl::Optional<float> inThreshold,
 atl::Optional<atl::Array<avl::Point2D>&> outCorners,
 atl::Optional<avl::Image&> outCornerResponseImage = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMonoImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inCornerResponseMethod	const CornerResponseMethod::Type			Method for computing corner response
→	inKernelSize	const int	1 – 10	3	Method kernel size
→	inThreshold	Optional<float>	0.0 – 255.0	50.0f	Threshold for corner response value, between 0 and 255, default value is taken from SelectThresholdValue on outCornerResponseImage and entropy method
←	outCorners	Optional<Array<Point2D>&>			Found corner points
←	outCornerResponseImage	Optional<Image&>		NIL	

Requirements

For input **inMonoImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCorners**, **outCornerResponseImage**.

Read more about Optional Outputs.

Description

The operation detects corners using either Harris or Kanade-Tomasi corner response method, depending on **inCornerResponseMethod**. For every square window of size **inKernelSize** a *convolution matrix* is computed:

$$M = \begin{pmatrix} \sum g_r^2 & \sum g_c g_r \\ \sum g_c g_r & \sum g_c^2 \end{pmatrix}$$

where the summation is performed over the whole window and g_r, g_c denote horizontal and vertical gradient respectively at the point.
Harris' corner response is computed the following way:

$$H = \det(M) - k\,\mathrm{tr}^2(M)$$

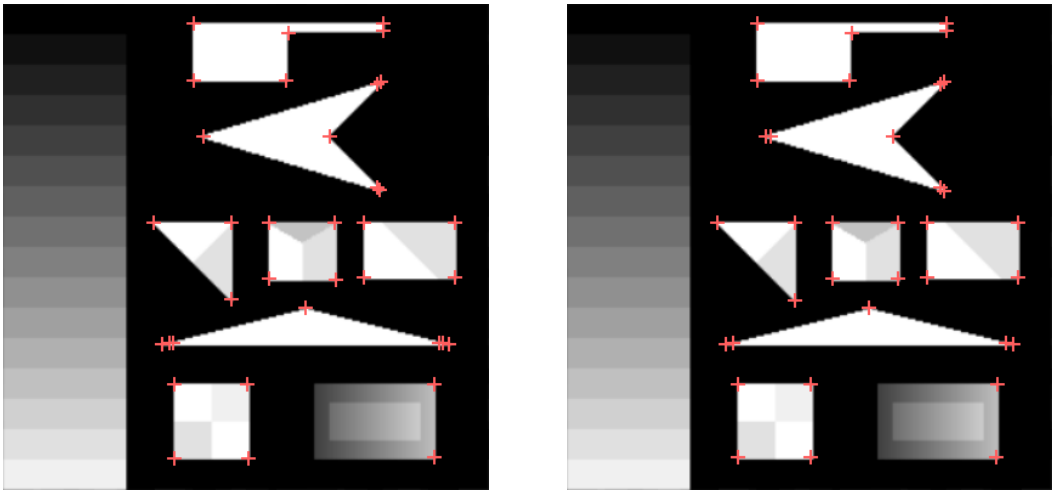
where k is a constant set to 0.01.
Kanade-Tomasi corner response is given by:

$$KT = \min(\lambda_1, \lambda_2)$$

where λ_1, λ_2 are eigenvalues of the convolution matrix.
Values H or KT give corner response image.

Then a few steps are performed in order to extract corner points. First, the normalized corner response function is thresholded with **inThreshold** with a small hysteresis, then the remained points are split into connected regions (blobs) and the center of each blob is determined.

Examples



*DetectCorners_CornerResponse with **inThreshold**=50, methods Harris and Kanade-Tomasi respectively.*

Remarks

Both methods give similar results and are quite fast. However, they tend to be less accurate than DetectCorners_Foerstner.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown algorithm in DetectCorners_CornerResponse.
DomainError	Not supported inMonoImage pixel format in DetectCorners_CornerResponse. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

See Also

- DetectCorners_Foerstner – Detects corners using the Foerstner algorithm.

DetectCorners_Foerstner

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Detects corners using the Foerstner algorithm.

Applications: Detection of characteristic points on an image.

Syntax

```
void avl::DetectCorners_Foerstner
(
 const avl::Image& inMonoImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inCornerQuality,
 const float inStrengthThreshold,
 const int inLocalness,
 atl::Array<avl::Point2D>& outPoints,
 avl::Image& diagRoundnessImage,
 avl::Image& diagStrengthImage
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inMonoImage	const Image&			Input image
➡	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
➡	inCornerQuality	const float	0.0 – 1.0	0.8f	Threshold on regularity of the corner
➡	inStrengthThreshold	const float	0.0 – 255.0	50.0f	Threshold on contrast of gradients forming the corner
➡	inLocalness	const int	1 – 11	3	How big-scaled the corners should be
⬅	outPoints	Array<Point2D>&			Found corner points
🔍	diagRoundnessImage	Image&			Calculated roundness for each input pixel
🔍	diagStrengthImage	Image&			Calculated strength for each pixel

Requirements

For input **inMonoImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Description

The operation detects corners using Foerstner algorithm. Its goal is to find corners defined as crossings of image edges.
For every square window of size 2*__inLocalness__+1 a *convolution matrix* is computed:

$$M = \begin{pmatrix} \sum g_r^2 & \sum g_c g_r \\ \sum g_c g_r & \sum g_c^2 \end{pmatrix}$$

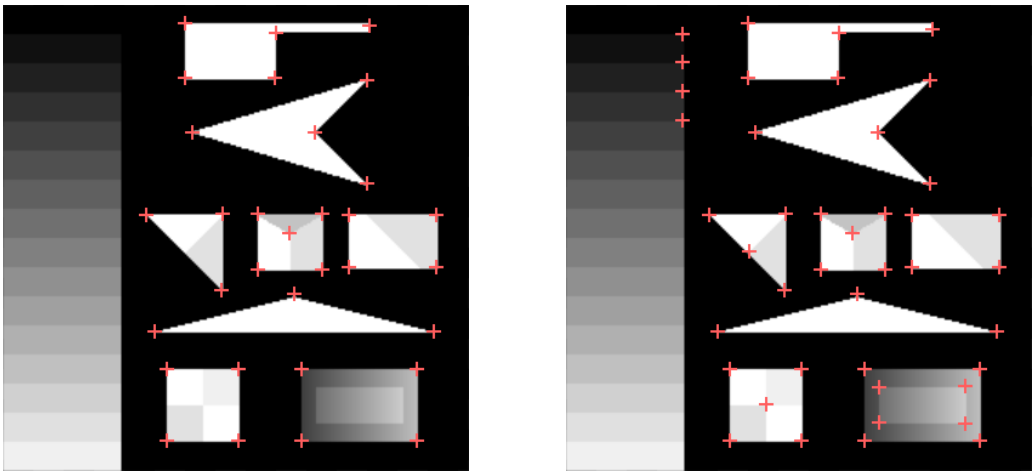
where the summation is performed over the whole window and g_r, g_c denote horizontal and vertical gradient respectively at the point.
Then the strength and so called *roundness* of the window is computed, where:

$$strength = \mathrm{tr}(M)$$

$$roundness = \mathrm{tr}(M)^2 / (4 * \det(M))$$

Roundness measures how similar are the gradients which form the corner.
Only windows with strength greater than __inStrengthThreshold__ and *roundness* greater than __inCornerQuality__ are considered. Then the non-maximum suppression on the window *roundness* is performed.
Finally the window's candidate for the corner is determined. It is done by minimizing square distance to all tangent lines (i.e. perpendicular to gradients) within the window, with distances weighted with gradient lengths.

Examples



DetectCorners_Foerstner *with different* ***inStrengthThreshold*** *values.*

Remarks

Strength of the window corresponds to average gradient strength within the window.
Roundness of the window is always between 0 and 1. For most applications __inCornerQuality__ values below 0.5 are not recommended.
Higher __inLocalness__ values (e.g. greater than 4) may help to get rid of noise on the image, but decrease precision.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inMonoImage pixel format in DetectCorners_Foerstner. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

- DetectCorners_CornerResponse – Detects corners using corner response method.

DetectLinePeak

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds line peaks on an image.

Applications: Created for applications with laser line detection.

Syntax

```
void avl::DetectLinePeak
(
 const avl::Image& inImage,
 avl::LinePeakDetectionMethod::Type inDetectionMethod,
 const float inThreshold,
 atl::Array<atl::Conditional<avl::Point2D> >& outLinePeakPoints,
 avl::Profile& diagLinePeakProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inDetectionMethod	LinePeakDetectionMethod::Type		MaximalPixel	Method used to determine exact line peak position
→	inThreshold	const float	0.0 – ∞	128.0f	Minimal value of a bright pixel
←	outLinePeakPoints	Array<Conditional<Point2D> >&			Line peak positions
🔍	diagLinePeakProfile	Profile&			Profile of line peak positions

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown input detection method in DetectLinePeak.

DetectLinePeak_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds line peaks on an image.

Applications: Created for applications with laser line detection.

Syntax

```
void avl::DetectLinePeak_Gauss
(
 const avl::Image& inImage,
 const float inStdDev,
 const float inKernelRelativeSize,
 const float inThreshold,
 atl::Array<atl::Conditional<avl::Point2D> >& outLinePeakPoints,
 avl::Profile& diagLinePeakProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inStdDev	const float	0.0 – ∞	4.0f	Standard deviation of the gaussian kernel
→	inKernelRelativeSize	const float	0.0 – 3.0	2.0f	A multiple of the standard deviation determining the size of the kernel
→	inThreshold	const float	0.0 – ∞	128.0f	Minimal value of a bright pixel
←	outLinePeakPoints	Array<Conditional<Point2D> >&			Line peak positions
🔍	diagLinePeakProfile	Profile&			Profile of line peak positions

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

MeasureObjectWidth

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Measures the width of an object using stripe detection.

Applications: Easy and precise measurement of distances between to straight parallel edges.

Syntax

```
void avl::MeasureObjectWidth
(
 const avl::Image& inImage,
 const atl::Array<avl::ScanMap>& inMeasurementMap,
 const avl::StripeScanParams& inStripeScanParams,
 avl::MeasureObjectMethod::Type inMeasureMethod,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 int inOutlierCount,
 atl::Conditional<float>& outObjectWidth,
 atl::Conditional<avl::Segment2D>& outSegment1,
 atl::Conditional<avl::Segment2D>& outSegment2,
 atl::Optional<atl::Array<atl::Conditional<avl::Stripe1D>>&> outStripes = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outBrightnessProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inMeasurementMap	const Array<ScanMap>&		Input measurement map
→	inStripeScanParams	const StripeScanParams&		Parameters controlling the object stripe extraction process
→	inMeasureMethod	MeasureObjectMethod::Type		Method used to measure the object
→	inStripeSelection	Selection::Type	Selection::Best	Selection mode of edges of the object
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	Selects a method for ignoring incorrectly detected points
→	inOutlierCount	int		Determines how many outlying points are rejected before the width is measured
←	outObjectWidth	Conditional<float>&		Width of the object
←	outSegment1	Conditional<Segment2D>&		First edge of the object
←	outSegment2	Conditional<Segment2D>&		Second edge of the object
←	outStripes	Optional<Array<Conditional<Stripe1D>>&>	NIL	Detected stripes
←	outBrightnessProfiles	Optional<Array<Profile>&>	NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>	NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

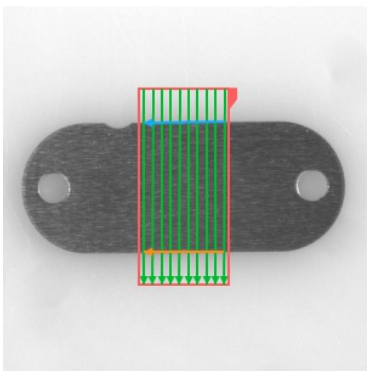
Description

The filter measures the width of an object present in an image. Internally, it performs a series of scans with ScanSingleStripe filter using **inMeasurementMap** and **inStripeScanParams**. The so obtained points are then used for computing two parallel segments by means of a slightly modified segment fitting routine. The process is supported by **inOutlierSuppression** parameter. Finally, having the aforementioned stripe widths and fitted segments' direction, the object width can be computed using a selected **inMeasureMethod** method. The **inOutlierCount** stripe widths most differing from the median width are not used in this step. The **inMeasurementMap** should be created with CreateMeasurementMap function. For the filter to work properly, the scan segments do not have to be necessarily perpendicular to the object edges.

Hints

- Define **inStripeScanParams.StripePolarity** to detect a particular edge type, and only that type.
- If some points are not found, try decreasing **inStripeScanParams.MinMagnitude**.
- If the object is more narrow than 6 pixels, change **inStripeScanParams.ProfileInterpolation** to **Quadratic3**.
- Experiment with **inOutlierSuppression** and **inOutlierCount** to deal with some amount of incorrectly detected points.
- Experiment with various values for **inMeasureMethod** to obtain best possible precision.

Examples



*MeasureObjectWidth performed on the sample image. Green segments are **diagScanSegments**, the other two are the found object edges.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid MeasurementMap in MeasureObjectWidth function. Use CreateMeasurementMap function to create it properly.

See Also

- ScanSingleStripe – Locates the strongest pair of edges across a given path.
- FitSegmentToEdges – Performs a series of 1D edge detections and finds a segment that best matches the detected points.

PhotometricStereo_ComputeHeightMap

Header: AVL.h
Namespace: avl
Module: Photometric

Computes the shape of the image object using surface normals.

Syntax

```
void avl::PhotometricStereo_ComputeHeightMap
(
 const avl::Image& inSurfaceNormals,
 avl::Image& outHeightMap
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceNormals	const Image&		
←	outHeightMap	Image&		

Requirements

For input **inSurfaceNormals** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	No proper structure available to compute heights for given image dimensions in PhotometricStereo_ComputeHeightMap. Please use PhotometricStereo_InitializeHeightMapStruct before using this function.
DomainError	Not supported inSurfaceNormals pixel format in PhotometricStereo_ComputeHeightMap. Supported formats: 2xReal.

PhotometricStereo_DestroyHeightMapStruct

Header: AVL.h
Namespace: avl
Module: Photometric

Destroys a structure used for computing height map in photometric stereo filter.

Syntax

```
void avl::PhotometricStereo_DestroyHeightMapStruct
(
 atl::Optional<int> inImageWidth,
 atl::Optional<int> inImageHeight
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageWidth	Optional<int>	1 – ∞	NIL	Width of the input images
→	inImageHeight	Optional<int>	1 – ∞	NIL	Height of the input images

PhotometricStereo_General_Perform

Header: AVL.h
Namespace: avl
Module: Photometric

Computes surface normals using images with light source in different places.

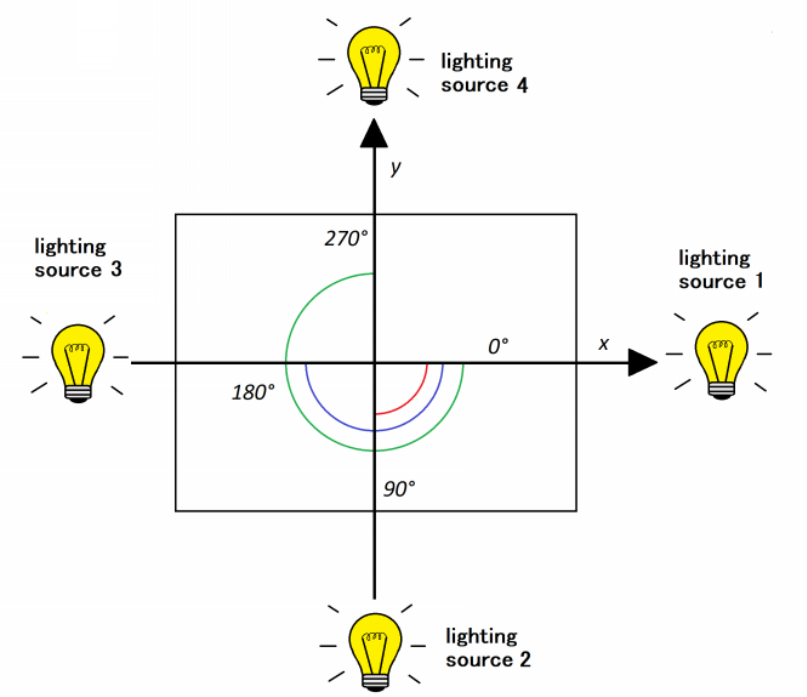
Syntax

```
void avl::PhotometricStereo_General_Perform
(
 const atl::Array<avl::Image>& inImages,
 const atl::Array<float>& inLightXYAngles,
 const atl::Array<float>& inLightZAngles,
 avl::Image& outSurfaceNormals,
 avl::Image& outIntensities,
 avl::Image& outAlbedo
)
```

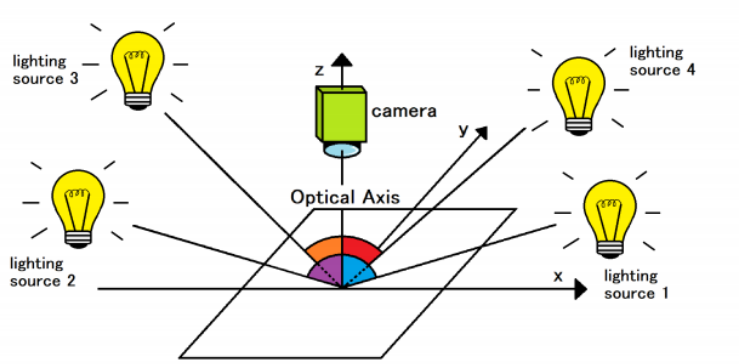
Parameters

	Name	Type	Default	Description
→	inImages	const Array<Image>&		
→	inLightXYAngles	const Array<float>&		Angle of light source on XY plane
→	inLightZAngles	const Array<float>&		Angle between light source and normal, where normal is camera optical axis
←	outSurfaceNormals	Image&		
←	outIntensities	Image&		
←	outAlbedo	Image&		

Examples



The picture above presents the angles to which the inLightXYAngles input refers.



The picture above presents the angles to which the inLightZAngles input refers.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different image dimensions on input in PhotometricStereo_General_Perform.
DomainError	Different types of images on input in PhotometricStereo_General_Perform.
DomainError	Inconsistent array sizes in PhotometricStereo_General_Perform.
DomainError	Not enough images on input in PhotometricStereo_General_Perform.
DomainError	Not single-channel image on input in PhotometricStereo_General_Perform.

See Also

- PhotometricStereo_Perform – Computes surface normals using four images with light source in different places.

PhotometricStereo_InitializeHeightMapStruct

Header: AVL.h
Namespace: avl
Module: Photometric

Creates a structure used for computing height map in photometric stereo filter.

Syntax

```
void avl::PhotometricStereo_InitializeHeightMapStruct
(
 const int inImageWidth,
 const int inImageHeight
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageWidth	const int	1 – ∞		Width of the input images
→	inImageHeight	const int	1 – ∞		Height of the input images

PhotometricStereo_Perform

Header: AVL.h
Namespace: avl
Module: Photometric

Computes surface normals using four images with light source in different places.

Syntax

```
void avl::PhotometricStereo_Perform
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 const avl::Image& inImage3,
 const avl::Image& inImage4,
 const float inXYAngleOffset,
 const float inZAngle,
 avl::Image& outSurfaceNormals,
 avl::Image& outIntensities,
 avl::Image& outAlbedo
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inImage3	const Image&		Third input image
→	inImage4	const Image&		Fourth input image
→	inXYAngleOffset	const float	0.0f	Angle of first light source on XY plane
→	inZAngle	const float	45.0f	Angle between light source and normal, where normal is camera optical axis
←	outSurfaceNormals	Image&		
←	outIntensities	Image&		
←	outAlbedo	Image&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

PhotometricStereo_SurfaceCurvature

Header: AVL.h
Namespace: avl
Module: Photometric

Computes the surface curvature using previously computed normals.

Syntax

```
void avl::PhotometricStereo_SurfaceCurvature
(
 const avl::Image& inSurfaceNormals,
 avl::CurvatureMeasure::Type inCurvatureMeasure,
 float inSmoothingStdDevX,
 atl::Optional<float> inSmoothingStdDevY,
 float inScale,
 float inOffset,
 avl::Image& outSurfaceCurvature
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceNormals	const Image&			
→	inCurvatureMeasure	CurvatureMeasure::Type		Gauss	Method used for measuring the surface curvature
→	inSmoothingStdDevX	float	0.0 – ∞	1.0f	Horizontal standard deviation of the gaussian smoothing applied to surface normals
→	inSmoothingStdDevY	Optional<float>	0.0 – ∞	NIL	Vertical standard deviation of the gaussian smoothing applied to surface normals
→	inScale	float	0.0 – ∞	1.0f	Scaling factor
→	inOffset	float		50.0f	Value added to rescaled curvature value
←	outSurfaceCurvature	Image&			

Requirements

For input **inSurfaceNormals** only pixel formats are supported: 2×uint8, 2×int8, 2×uint16, 2×int16, 2×int32, 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inSurfaceNormals pixel format in PhotometricStereo_SurfaceCurvature. Supported formats: 2xUInt8, 2xInt8, 2xUInt16, 2xInt16, 2xInt32, 2xReal.

AddSpatialMaps

Header: AVL.h
Namespace: avl
Module: Calibration

Combines two spatial maps.

Applications: Makes it possible to use single RemapImage filter even if there are two or more image remapping operations (e.g. lens distortion + perspective distortion).

Syntax

```
void avl::AddSpatialMaps
(
 const avl::SpatialMap& inSpatialMap1,
 const avl::SpatialMap& inSpatialMap2,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap1	const SpatialMap&		
→	inSpatialMap2	const SpatialMap&		
←	outSpatialMap	SpatialMap&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different spatial maps image types in AddSpatialMaps.

CombineSpatialMaps

Header: AVL.h
Namespace: avl
Module: Calibration

Combines two spatial maps.

Applications: Makes it possible to use single RemapImage filter even if there are two or more image remapping operations (e.g. lens distortion + perspective distortion).

Syntax

```
void avl::CombineSpatialMaps
(
 const avl::SpatialMap& inSpatialMap1,
 const avl::SpatialMap& inSpatialMap2,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap1	const SpatialMap&		
→	inSpatialMap2	const SpatialMap&		
←	outSpatialMap	SpatialMap&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different spatial map interpolations in CombineSpatialMaps.
DomainError	Incompatible spatial map dimensions in CombineSpatialMaps.
DomainError	Incompatible spatial map pixel types in CombineSpatialMaps.

ConvertMatrixMapsToSpatialMap

Header: AVL.h
Namespace: avl
Module: Calibration

Joins two matrices of coordinates to produce a SpatialMap for use in RemapImage.

Syntax

```
void avl::ConvertMatrixMapsToSpatialMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Matrix& inMatrixX,
 const avl::Matrix& inMatrixY,
 avl::InterpolationMethod::Type inInterpolationMethod,
 bool inRoundingOpenCV,
 avl::SpatialMap& outSpatialMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		Information about dimensions, depth and pixel type of the image
→	inMatrixX	const Matrix&		Map of real X coordinates
→	inMatrixY	const Matrix&		Map of real Y coordinates
→	inInterpolationMethod	InterpolationMethod::Type	Bilinear	
→	inRoundingOpenCV	bool		Use same interpolation convention as cvRemap
←	outSpatialMap	SpatialMap&		Output spatial map
←	outOutputRegion	Optional<Region&>	NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Remarks

The two source matrices contain real-valued coordinates – if **inMatrixX[a, b]** = *x* and **inMatrixY[a, b]** = *y*, then the RemapImage filter applied with this map will generate the **outImage[a, b]** pixel based on pixels around (*x*, *y*) in **inImage**.

One example of application of this filter is the conversion of matrix maps generated with the OpenCV filter OpenCV **InitUndistortRectifyMap** function.

The **inRoundingOpenCV** parameter should be set to true if the matrices passed to this filter were obtained from an OpenCV function, like OpenCV **InitUndistortRectifyMap** function. This ensures that the results of RemapImage will be identical to OpenCV **Remap** function used with the same interpolation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Format of an empty image on input in ConvertMatrixMapsToSpatialMap.
DomainError	Input matrices must have equal sizes in ConvertMatrixMapsToSpatialMap.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ConvertSpatialMapToMatrixMaps – Splits a spatial map into two matrices of source coordinates.

ConvertSpatialMap

Header: AVL.h
Namespace: avl
Module: Calibration

Converts a spatial map to a different format.

Syntax

```
void avl::ConvertSpatialMap
(
 const avl::SpatialMap& inSpatialMap,
 atl::Optional<avl::PlainType::Type> inNewPixelType,
 atl::Optional<int> inNewDepth,
 const int inNewPitchAlignment,
 atl::Optional<int> inNewPitch,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSpatialMap	const SpatialMap&			
→	inNewPixelType	Optional<PlainType::Type>		NIL	
→	inNewDepth	Optional<int>	1 – 4	NIL	
→	inNewPitchAlignment	const int	0 – +∞	16	
→	inNewPitch	Optional<int>	1 – +∞	NIL	
←	outSpatialMap	SpatialMap&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect inSpatialMap map in ConvertSpatialMap.

ConvertSpatialMapToMatrixMaps

Header: AVL.h
Namespace: avl
Module: Calibration

Splits a spatial map into two matrices of source coordinates.

Syntax

```
void avl::ConvertSpatialMapToMatrixMaps
(
 const avl::SpatialMap& inSpatialMap,
 bool inRoundingOpenCV,
 avl::Matrix& outMatrixX,
 avl::Matrix& outMatrixY
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap	const SpatialMap&		
→	inRoundingOpenCV	bool		Use same interpolation convention as cvRemap
←	outMatrixX	Matrix&		Map of real X coordinates
←	outMatrixY	Matrix&		Map of real Y coordinates

Description

This operation allows to inspect the accessed coordinates in the image being remapped.

If the input SpatialMap uses the **nearest neighbor interpolation**, it is not possible to recover the exact source coordinates. In that case the pixel center, or the top left corner when using **inRoundingOpenCV** set to **True**, is taken as an approximation.

Remarks

For pixels in the input spatial map which are not well defined, an artificial pair of invalid coordinates, (-10, -10), is returned.

The **inRoundingOpenCV** parameter should be set to True if the matrices will be used with OpenCV **Remap** function. This ensures the results of OpenCV **Remap** function will be the same as of RemapImage used with the input SpatialMap.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ConvertMatrixMapsToSpatialMap – Joins two matrices of coordinates to produce a SpatialMap for use in RemapImage.
- ConvertSpatialMap_ToNearest – Converts any spatial map to NearestNeighbour interpolation.

ConvertSpatialMap_ToNearest

Header: AVL.h
Namespace: avl
Module: Calibration

Converts any spatial map to NearestNeighbour interpolation.

Applications: Reducing quality for the purpose of speed.

Syntax

```
void avl::ConvertSpatialMap_ToNearest
(
 const avl::SpatialMap& inSpatialMap,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap	const SpatialMap&		
←	outSpatialMap	SpatialMap&		

Description

This operation can be used to convert a SpatialMap using Bilinear interpolation to one using nearest neighbour interpolation. If the input SpatialMap is already nearest neighbour, it is returned unchanged.

Remarks

The compatible ImageFormat remains the same as for the input SpatialMap in any case.

This conversion is not reversible, because a SpatialMap with nearest Neighbour interpolation holds less information than one with Bilinear interpolation.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ConvertMatrixMapsToSpatialMap – Joins two matrices of coordinates to produce a SpatialMap for use in RemapImage.
- ConvertSpatialMapToMatrixMaps – Splits a spatial map into two matrices of source coordinates.

CreateCylinderMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map for transformations from a cylinder surface to a flat rectangle.

Applications: Inspection of the surface of bottles and other cylindrical objects. The result is used by RemapImage.

Syntax

```
void avl::CreateCylinderMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Rectangle2D& inCylinderRectangle,
 const float inCylinderRadiusCorrection,
 atl::Optional<avl::Point2D> inOpticalAxis,
 atl::Optional<int> inNewWidth,
 atl::Optional<int> inNewHeight,
 const int inMargin,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::CylinderMappingMode::Type inCylinderMappingMode,
 avl::SpatialMap& outSpatialMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Information about dimensions, depth and pixel type of the image
→	inCylinderRectangle	const Rectangle2D&			Bounding rectangle of the cylinder
→	inCylinderRadiusCorrection	const float	0.0 – ∞	0.0f	How many pixels the cylinder radius is larger than the visible circle radius
→	inOpticalAxis	Optional<Point2D>		NIL	Coordinates of the camera optical axis (Auto = image center)
→	inNewWidth	Optional<int>	1 – ∞	NIL	Width of an image created by output spatial map application
→	inNewHeight	Optional<int>	1 – ∞	NIL	Height of an image created by output spatial map application
→	inMargin	const int	0 – ∞	0	Width of the cylinder extreme points zone excluded from spatial map
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	Interpolation method used in extraction of image pixel values
→	inCylinderMappingMode	CylinderMappingMode::Type			Determines which pixels of the mapped cylinder have to be within the given rectangle.
←	outSpatialMap	SpatialMap&			Output spatial map
←	outOutputRegion	Optional<Region&>		NIL	Pixels set by the spatial map application

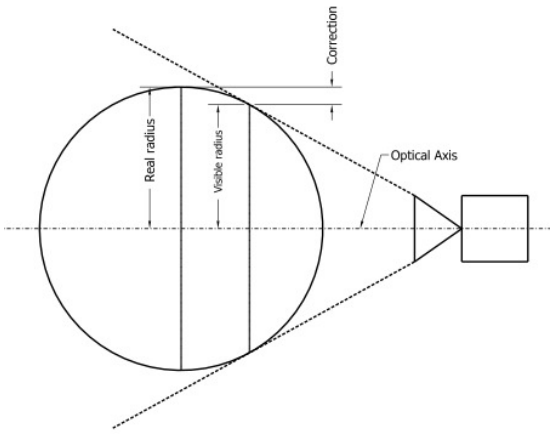
Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Description

The filter creates a spatial map that allows to transform a cylinder surface to a flat rectangle. The **inCylinderRectangle** should be the minimal rectangle that contains the given cylinder. Because of the presence of a camera, the cylinder radius is not equal to but greater than the width of the input rectangle. To compensate the difference, **inCylinderRadiusCorrection** has to be properly set experimentally. Another important parameter is the **inOpticalAxis** input that represents the coordinates of the camera optical axis, i.e. it shows which pixel is directly under the camera. It is set to the input image center by default.



Examples

*Results of applying RemapImage with a spatial map created with the **CreateCylinderMap** filter.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cylinder stripe within rectangle thinner then a single pixel in CreateCylinderMap.
DomainError	Empty domain in CreateCylinderMap.
DomainError	Mapped image width too large in CreateCylinderMap.
DomainError	Margin too large in CreateCylinderMap.

CreateImageInversePolarTransformMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map representing an image inverse polar transform.

Applications: Data preprocessing for fast inverse polar transform. The result is used by RemapImage.

Syntax

```
void avl::CreateImageInversePolarTransformMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Point2D& inCenter,
 avl::PolarSpaceType::Type inSpaceType,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outPolarMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		Information about dimensions, depth and pixel type of the image
→	inCenter	const Point2D&		
→	inSpaceType	PolarSpaceType::Type		Method of transformation
→	inInterpolationMethod	InterpolationMethod::Type	Bilinear	Interpolation method used in extraction of image pixel values
←	outPolarMap	SpatialMap&		Output spatial map
←	outOutputRegion	Optional<Region&>	NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Description

The operation generates map that describes image transformation from polar or log-polar space to euclidean space. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive. Usually creating map and then using RemapImage is faster than ImageInversePolarTransform. For more information see ImageInversePolarTransform.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ImagePolarTransform – Transforms an image to polar or log-polar space.

CreateImagePolarTransformMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map representing an image polar transform.

Applications: Data preprocessing for fast image polar transform. The result is used by RemapImage.

Syntax

```
void avl::CreateImagePolarTransformMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Point2D& inCenter,
 avl::PolarSpaceType::Type inSpaceType,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outPolarMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		Information about dimensions, depth and pixel type of the image
→	inCenter	const Point2D&		
→	inSpaceType	PolarSpaceType::Type		Method of transformation
→	inInterpolationMethod	InterpolationMethod::Type	Bilinear	Interpolation method used in extraction of image pixel values
←	outPolarMap	SpatialMap&		Output spatial map
←	outOutputRegion	Optional<Region&>	NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Description

The operation generates map that describes image transformation to polar or log-polar space. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive. Usually creating map and then using RemapImage is faster than ImagePolarTransform. For more information see ImagePolarTransform.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ImagePolarTransform – Transforms an image to polar or log-polar space.

CreateImageResizeMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map representing an image resizing.

Applications: Data preprocessing for fast image resize between two constant sizes. The result is used by RemapImage.

Syntax

```
void avl::CreateImageResizeMap
(
 const avl::ImageFormat& inImageFormat,
 int inNewWidth,
 int inNewHeight,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outResizeMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Information about dimensions, depth and pixel type of the image
→	inNewWidth	int	1 – ∞		Width of an image created by output spatial map application
→	inNewHeight	int	1 – ∞		Height of an image created by output spatial map application
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	Interpolation method used in extraction of image pixel values
←	outResizeMap	SpatialMap&			Output spatial map
←	outOutputRegion	Optional<Region&>		NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Description

The operation generates map that stretches or shrinks the image. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive. Usually creating map and then using RemapImage is faster than ResizeImage.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- ResizeImage – Enlarges or shrinks an image to new dimensions.

CreateImageRotationMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map representing an image rotation.

Applications: Preprocessing data for fast image rotation by a constant angle. The result is used by RemapImage.

Syntax

```
void avl::CreateImageRotationMap
(
 const avl::ImageFormat& inImageFormat,
 float inAngle,
 avl::RotationSizeMode::Type inSizeMode,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outRotationMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		Information about dimensions, depth and pixel type of the image
→	inAngle	float	45.0f	The angle of rotation
→	inSizeMode	RotationSizeMode::Type		
→	inInterpolationMethod	InterpolationMethod::Type	Bilinear	Interpolation method used in extraction of image pixel values
←	outRotationMap	SpatialMap&		Output spatial map
←	outOutputRegion	Optional<Region&>	NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Description

The operation generates map that describes rotation mapping. Dimensions of the resulting image depends on **inSizeMode**. In 'Fit' mode size is extended to fit the rotated image. In 'Preserve' mode size of source image is left unchanged and part of rotated image may be lost. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive. Usually creating map and then using RemapImage is faster than RotateImage. **outOutputRegion** return region, which can be calculated by RemapImage.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.
- RotateImage – Rotates an image clockwise.

CreateMatrixTransformMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map which performs transform defined as a 3x3 homography matrix.

Syntax

```
void avl::CreateMatrixTransformMap
(
 const avl::ImageFormat& inImageFormat,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Matrix& inTransformMatrix,
 const atl::Optional<avl::Size>& inNewSize,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inTransformMatrix	const Matrix&		3x3 homography matrix.
→	inNewSize	const Optional<Size>&	NIL	New image size after remapping
→	inInterpolationMethod	InterpolationMethod::Type		Interpolation method used in extraction of image pixel values
←	outSpatialMap	SpatialMap&		Calculated spatial map

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input transformation matrix must have dimensions 3x3 in CreateMatrixTransformMap.

CreatePerspectiveMap_Path

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a perspective transform map from planes defined by paths.

Applications: Data preprocessing for fast perspective correction. The result is used by RemapImage.

Syntax

```
void avl::CreatePerspectiveMap_Path
(
 const avl::ImageFormat& inImageFormat,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Path& inImagePath,
 atl::Optional<const avl::Path&> inTargetPath,
 atl::Optional<const avl::Size&> inNewSize,
 const avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outSpatialMap,
 avl::Matrix& outTransformMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inImagePath	const Path&		Plane defined by a closed path made of 4 points
→	inTargetPath	Optional<const Path&>	NIL	Target plane. If NIL then image corners are used starting from (0,0) (Width, 0) (Width, Height), (0, Height)
→	inNewSize	Optional<const Size&>	NIL	New image size after remapping
→	inInterpolationMethod	const InterpolationMethod::Type		Interpolation method used in extraction of image pixel values
←	outSpatialMap	SpatialMap&		Calculated spatial map
←	outTransformMatrix	Matrix&		Used transform matrix

Description

This operation computes a SpatialMap which can be later used for removing a perspective distortion from an image.

The operation maps the input path (**inImagePath**) into the target path (**inTargetPath**). If the **inTargetPath** input is set to Auto this path will be made from the corner points of the input image. Both paths must be closed and must be made of four points.

The input **inNewSize** allows rescaling of the output image.

The **inImageFormat** format is necessary for preparation of a spatial map.

The **outTransformMatrix** output allows verifying the found transformation.

Examples

Image before and after the perspective transform created by CreatePerspectiveMap_Path.

Remarks

This filter is a good choice for local perspective distortion removal – such as "unwrapping" boxes, as is depicted by the example above. Applications concerned with observing real-world flat surfaces (such as observing conveyor belts) should use methods that are more accurate. Please refer to: **Machine Vision Guide – Camera Calibration and World Coordinates**

Notice that both **inImagePath** path and **inTargetPath** must be made of four points. This filter creates point to point transform so the changing points order in paths may yield an unexpected result.

The best way to understand the relation between **inImagePath** and **inTargetPath** is to present the first of them on the input image and the second on the background of remapped image.

*The image before remapping on the left (with **inImagePath**) and the image after on the right (with **inTargetPath**).*

Errors

List of possible exceptions:

Error type	Description
DomainError	inImagePath input must contain a closed path created from 4 points in CreatePerspectiveMap_Path.
DomainError	inTargetPath input must contain a closed path created from 4 points in CreatePerspectiveMap_Path.

See Also

- CreatePerspectiveMap_Points – Creates a perspective transform map from four points denoting a rectangle in the world coordinates.
- RemapImage – Applies a precomputed image transform, defined by a spatial map object.

CreatePerspectiveMap_Points

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a perspective transform map from four points denoting a rectangle in the world coordinates.

Applications: Data preprocessing for fast perspective correction. The result is used by RemapImage.

Syntax

```
void avl::CreatePerspectiveMap_Points
(
 const avl::ImageFormat& inImageFormat,
 atl::Optional<const avl::Region&> inRoi,
 const atl::Array<avl::Point2D>& inImagePoints,
 atl::Optional<const atl::Array<avl::Point2D>&> inTargetPoints,
 atl::Optional<const avl::Size&> inNewSize,
 const avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outSpatialMap,
 avl::Matrix& outTransformMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inImagePoints	const Array<Point2D>&		Points define real object plane corners.
→	inTargetPoints	Optional<const Array<Point2D>&>	NIL	Points define target plane corners. If NIL then image corners are used starting from (0,0) (Width, 0) (Width, Height), (0, Height)
→	inNewSize	Optional<const Size&>	NIL	New image size after remapping
→	inInterpolationMethod	const InterpolationMethod::Type		Interpolation method used in extraction of image pixel values
←	outSpatialMap	SpatialMap&		Created SpatialMap with perspective transform
←	outTransformMatrix	Matrix&		Used transform matrix

Description

This operation computes a SpatialMap which can be later used for removing a perspective distortion from an image.

The operation maps the input image points (**inImagePoints**) onto locations described by the target points (**inTargetPoints**). If the **inTargetPoints** input is set to Auto this array will be made from the corner points of the input image. Both array must contains four points.

The input **inNewSize** allows rescaling of the output image.

The **inImageFormat** format is necessary for preparation of a spatial map.

The **outTransformMatrix** output allows verifying the found transformation.

Remarks

This filter is a good choice for local perspective distortion removal – such as "unwrapping" boxes, as is depicted by the example above. Applications concerned with observing real-world flat surfaces (such as observing conveyor belts) should use methods that are more accurate. Please refer to: **Machine Vision Guide – Camera Calibration and World Coordinates**

Notice that both **inImagePoints** array and **inTargetPoints** must be made of four points. This filter creates point to point transform so changing the points' order in the array may yield an unexpected result.

The best way to understand the relation between **inImagePoints** and **inTargetPoints** is to present the first of them on the input image and the second on the background of the remapped image.

*The image before remapping on the left (with **inImagePoints**) and the image after on the right (with **inTargetPoints**) created by CreatePerspectiveMap_Path.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Each of input array must contain four points in CreatePerspectiveMap_Points.

See Also

- CreatePerspectiveMap_Path – Creates a perspective transform map from planes defined by paths.
- RemapImage – Applies a precomputed image transform, defined by a spatial map object.

CreatePincushionMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map for removing/adding pincushion distortion, using divisional lens distortion model.

Applications: The easiest way to remove typical lens distortion. Use together with RemapImage.

Syntax

```
void avl::CreatePincushionMap
(
 const avl::ImageFormat& inImageFormat,
 const float inKappa,
 const atl::Optional<avl::Point2D>& inCenter,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outMap
)
```

Parameters

	Name	Type	Default	Description
→	inImageFormat	const ImageFormat&		
→	inKappa	const float		
→	inCenter	const Optional<Point2D>&	NIL	
→	inInterpolationMethod	InterpolationMethod::Type		
←	outMap	SpatialMap&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

CreateSphereMap

Header: AVL.h
Namespace: avl
Module: Calibration

Creates a spatial map for transformations from a sphere surface to a flat rectangle.

Applications: Inspection of the surface of balls and other spherical objects. The result is used by RemapImage.

Syntax

```
void avl::CreateSphereMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Rectangle2D& inSphereRectangle,
 const float inSphereRadiusCorrection,
 atl::Optional<int> inNewDimension,
 const int inMargin,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::SpatialMap& outSpatialMap,
 atl::Optional<avl::Region&> outOutputRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Information about dimensions, depth and pixel type of the image
→	inSphereRectangle	const Rectangle2D&			Bounding rectangle of a sphere
→	inSphereRadiusCorrection	const float	0.0 – ∞	0.0f	How many pixels the sphere radius is larger than the visible circle radius
→	inNewDimension	Optional<int>	1 – ∞	NIL	Width and height of an image created by output spatial map application
→	inMargin	const int	0 – ∞	0	Width of the sphere extreme points zone excluded from spatial map
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	Interpolation method used in extraction of image pixel values
←	outSpatialMap	SpatialMap&			Output spatial map
←	outOutputRegion	Optional<Region&>		NIL	Pixels set by the spatial map application

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputRegion**.

Read more about Optional Outputs.

Examples

*Results of applying RemapImage with a spatial map created with the **CreateSphereMap** filter.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty rectangle on input in CreateSphereMap.

CropSpatialMap

Header: AVL.h
Namespace: avl
Module: Calibration

Crops a spatial map to the specified input and output boxes.

Syntax

```
void avl::CropSpatialMap
(
 const avl::SpatialMap& inSpatialMap,
 const avl::Box& inInputCroppingBox,
 const avl::Box& inOutputCroppingBox,
 avl::SpatialMap& outCroppedSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap	const SpatialMap&		
→	inInputCroppingBox	const Box&		
→	inOutputCroppingBox	const Box&		
←	outCroppedSpatialMap	SpatialMap&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect inSpatialMap map in CropSpatialMap.

LoadSpatialMap

Header: AVL.h
Namespace: avl
Module: Calibration

Deserializes a SpatialMap object from a AVDATA file.

Syntax

```
void avl::LoadSpatialMap
(
 const atl::File& inFilename,
 avl::SpatialMap& outSpatialMap
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outSpatialMap	SpatialMap&		Deserialized SpatialMap

RemapImage

Header: AVL.h
Namespace: avl
Module: Calibration

Applies a precomputed image transform, defined by a spatial map object.

Applications: Fast (precomputed) image transformations, especially for view undistortion or object geometry correction (e.g. pos recognition of labels on cylindrical bottles).

Syntax

```
void avl::RemapImage
(
 const avl::Image& inImage,
 const avl::SpatialMap& inSpatialMap,
 atl::Optional<const avl::Region&> inMapRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inSpatialMap	const SpatialMap&		Definition of the transformation
→	inMapRoi	Optional<const Region&>	NIL	Defines which elements of the spatial map are valid
←	outImage	Image&		Output image

Description

The operation applies an arbitrary spatial transformation to an image using a SpatialMap object. The input image has to be compatible with the given map. You can check if a map is compatible with an image using TestSpatialMapApplicability.

Hints

- Connect the **inSpatialMap** input with a spatial map. This can be for example the result of the CreateSphereMap function or similar.

Remarks

Read more about how to handle images from camera in Camera Calibration article.

Hardware Acceleration

This operation is optimized for SSE4 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for AVX2 technology for pixels of type: 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect SpatialMap on input in RemapImage.

See Also

- TestSpatialMapApplicability – Checks if a spatial map may be applied to transform the given image.

SaveSpatialMap

Header: AVL.h
Namespace: avl
Module: Calibration

Serializes a SpatialMap object to an AVDATA file.

Syntax

```
void avl::SaveSpatialMap
(
 const avl::SpatialMap& inSpatialMap,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inSpatialMap	const SpatialMap&		SpatialMap to be serialized
➡	inFilename	const File&		Name of the target file

TestSpatialMapApplicability

Header: AVL.h
Namespace: avl
Module: Calibration

Checks if a spatial map may be applied to transform the given image.

Syntax

```
void avl::TestSpatialMapApplicability
(
 const avl::Image& inImage,
 const avl::SpatialMap& inSpatialMap,
 bool& outAreCompatible
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	const Image&		Input image
➡	inSpatialMap	const SpatialMap&		
⬅	outAreCompatible	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect SpatialMap on input in TestSpatialMapApplicability.

UnmapPoint

Header: AVL.h
Namespace: avl
Module: Calibration

Computes locations of image point on the source image from image point location on remapped image.

Syntax

```
void avl::UnmapPoint
(
 const avl::SpatialMap& inSpatialMap,
 const avl::Point2D& inPoint,
 atl::Conditional<avl::Point2D>& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialMap	const SpatialMap&		
→	inPoint	const Point2D&		
←	outPoint	Conditional<Point2D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect spatial map in UnmapPoint.

16. Profile Combinators

Table of content:

- MinimumProfile_OfLoop
- MultiplyProfiles
- MultiplyProfiles_OfArray
- MultiplyProfiles_OfLoop
- SubtractProfiles

AccumulateProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a profile in a loop by concatenating individual values.

Syntax

```
void avl::AccumulateProfile
(
 const float inValue,
 atl::Optional<int> inMaxCount,
 bool inReset,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValue	const float			
→	inMaxCount	Optional<int>	0 – ∞	NIL	Number of last values that are remembered
→	inReset	bool			Reset accumulator state
←	outProfile	Profile&			Output profile

Errors

List of possible exceptions:

Error type	Description
DomainError	inMaxCount cannot be negative in AccumulateProfile.

AddProfiles

Header: AVL.h
Namespace: avl
Module: FoundationPro

Adds two profiles value by value.

Syntax

```
void avl::AddProfiles
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in AddProfiles.
DomainError	Input profiles have different X coordinates in AddProfiles.

AddProfiles_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Adds profiles of an array value by value.

Syntax

```
void avl::AddProfiles_OfArray
(
 const atl::Array<avl::Profile>& inProfileArray,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfileArray	const Array<Profile>&		
←	outProfile	Profile&		Output profile

Description

Array version of AddProfiles.

See Also

- AddProfiles - Adds two profiles value by value.

AddProfiles_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationPro

Adds profiles appearing in consecutive iterations value by value.

Syntax

```
void avl::AddProfiles_OfLoop
(
 ProfileCombinators_OfLoopState& ioState,
 const avl::Profile& inProfile,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
	ioState	ProfileCombinators_OfLoopState&		Object used to maintain state of the function.
	inProfile	const Profile&		Input profile
	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile** and **outProfile**

Read more about In-place Computation.

Description

Loop version of AddProfiles.

See Also

- AddProfiles - Adds two profiles value by value.

DifferenceProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes profile representing difference between corresponding values of given profiles.

Syntax

```
void avl::DifferenceProfile
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in DifferenceProfile.
DomainError	Input profiles have different X coordinates in DifferenceProfile.

DivideProfiles

Header: AVL.h
Namespace: avl
Module: FoundationPro

Divides two profiles value by value.

Syntax

```
void avl::DivideProfiles
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in DivideProfiles.
DomainError	Input profiles have different X coordinates in DivideProfiles.
DomainError	One of the second profile's values equals zero in DivideProfiles.

JoinProfiles

Header: AVL.h
Namespace: avl
Module: FoundationPro

Concatenates two profiles into one.

Syntax

```
void avl::JoinProfiles
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

MaximumProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the maximum of two profiles point by point.

Syntax

```
void avl::MaximumProfile
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in MaximumProfile.
DomainError	Input profiles have different X coordinates in MaximumProfile.

MaximumProfile_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the maximum of profiles of an array.

Syntax

```
void avl::MaximumProfile_OfArray
(
 const atl::Array<avl::Profile>& inProfileArray,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfileArray	const Array<Profile>&		
←	outProfile	Profile&		Output profile

Description

Array version of MaximumProfile.

See Also

- MaximumProfile - Computes the maximum of two profiles point by point.

MaximumProfile_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the maximum of profiles appearing in consecutive iterations.

Syntax

```
void avl::MaximumProfile_OfLoop
(
 ProfileCombinators_OfLoopState& ioState,
 const avl::Profile& inProfile,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
	ioState	ProfileCombinators_OfLoopState&		Object used to maintain state of the function.
	inProfile	const Profile&		Input profile
	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile** and **outProfile**

Read more about In-place Computation.

Description

Loop version of MaximumProfile.

See Also

- MaximumProfile - Computes the maximum of two profiles point by point.

MinimumProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the minimum of two profiles point by point.

Syntax

```
void avl::MinimumProfile
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in MinimumProfile.
DomainError	Input profiles have different X coordinates in MinimumProfile.

MinimumProfile_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the minimum of profiles of an array.

Syntax

```
void avl::MinimumProfile_OfArray
(
 const atl::Array<avl::Profile>& inProfileArray,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfileArray	const Array<Profile>&		
←	outProfile	Profile&		Output profile

Description

Array version of MinimumProfile.

See Also

- MinimumProfile - Computes the minimum of two profiles point by point.

MinimumProfile_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the minimum of profiles appearing in consecutive iterations.

Syntax

```
void avl::MinimumProfile_OfLoop
(
 ProfileCombinators_OfLoopState& ioState,
 const avl::Profile& inProfile,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
	ioState	ProfileCombinators_OfLoopState&		Object used to maintain state of the function.
	inProfile	const Profile&		Input profile
	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile** and **outProfile**

Read more about In-place Computation.

Description

Loop version of MinimumProfile.

See Also

- MinimumProfile - Computes the minimum of two profiles point by point.

MultiplyProfiles

Header: AVL.h
Namespace: avl
Module: FoundationPro

Multiplies two profiles value by value.

Syntax

```
void avl::MultiplyProfiles
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in MultiplyProfiles.
DomainError	Input profiles have different X coordinates in MultiplyProfiles.

MultiplyProfiles_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Multiplies profiles of an array value by value.

Syntax

```
void avl::MultiplyProfiles_OfArray
(
 const atl::Array<avl::Profile>& inProfileArray,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfileArray	const Array<Profile>&		
←	outProfile	Profile&		Output profile

Description

Array version of MultiplyProfiles.

See Also

- MultiplyProfiles - Multiplies two profiles value by value.

MultiplyProfiles_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationPro

Multiplies profiles appearing in consecutive iterations value by value.

Syntax

```
void avl::MultiplyProfiles_OfLoop
(
 ProfileCombinators_OfLoopState& ioState,
 const avl::Profile& inProfile,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
	ioState	ProfileCombinators_OfLoopState&		Object used to maintain state of the function.
	inProfile	const Profile&		Input profile
	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile** and **outProfile**

Read more about In-place Computation.

Description

Loop version of MultiplyProfiles.

See Also

- MultiplyProfiles - Multiplies two profiles value by value.

SubtractProfiles

Header: AVL.h
Namespace: avl
Module: FoundationPro

Subtracts two profiles value by value.

Syntax

```
void avl::SubtractProfiles
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
←	outProfile	Profile&		Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile1** and **outProfile**, **inProfile2** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in SubtractProfiles.
DomainError	Input profiles have different X coordinates in SubtractProfiles.

17. Image Conversions

Table of content:

- SplitChannels_OrNil

AddChannels

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image by summing the values of the input image channels.

Syntax

```
void avl::AddChannels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		output mono image

Description

This operation sums values of the given **inImage** image channels to obtain a monochromatic image.

Examples

Image with one channel on the input of the filter (on the left) doesn't affect the image - see the image on the right.

Input RGB image (on the left) converted to single-channel image (on the right) with pixel values obtained from summing values of input image channels. For example, if a pixel from input image in each R, G and B channel has values {255, 0, 0}, corresponding pixel in the output image will have value {255} (because 255 + 0 + 0 = 255).

Hardware Acceleration

This operation is optimized for AVX2 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8, 2xUINT16, 3xUINT16, 4xUINT16.

This operation is optimized for SSSE3 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8, 2xUINT16, 3xUINT16, 4xUINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AddChannels.

See Also

- AddChannels_Saturation – Creates a monochromatic image by summing the values of the input image channels with saturation.
- AverageChannels – Creates a monochromatic image by averaging the input image channels.
- AverageChannels_Weighted – Creates a monochromatic image from weighted averages of the input image channels.

AddChannels_Saturation

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image by summing the values of the input image channels with saturation.

Syntax

```
void avl::AddChannels_Saturation
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		output mono image

Description

This operation sums with saturation values of the given **inImage** image channels to obtain a monochromatic image.

Firstly, the filter performs ordinary addition of pixel values from each channel. Then, comparison with maximal allowable value for single channel is performed. Such value depends on the pixel type – for example, if the pixel type is UInt8, maximal allowable value for each single channel is 255. The result of addition with saturation is chosen as a minimal value of computed sum and allowable maximum – for example, if the input image has three R, G, B channels and pixel type of UInt8, the result of addition with saturation is chosen as min(R + G + B, 255).

Examples

Image with one channel on the input of the filter (on the left) doesn't affect the image – see the image on the right.

Input RGB image (on the left) converted to single-channel image (on the right) with pixel values obtained from summing with saturation values of input image channels. In the picture on the left-hand side, pixel values in the colorful squares are {255, 255, 0}, {255, 0, 255} and {0, 255, 255}, and their type is UInt8. After addition with saturation, values of corresponding pixels in the output image will be {255} – because maximal value for UInt8 pixels is 255 and min(255 + 0 + 255, 255) is 255.

Hardware Acceleration

This operation is optimized for AVX2 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8, 2xUINT16, 3xUINT16, 4xUINT16.

This operation is optimized for SSSE3 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8, 2xUINT16, 3xUINT16, 4xUINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AddChannels_Saturation.

AppendImageChannel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Appends a single valued channel to the input image.

Syntax

```
void avl::AppendImageChannel
(
 const avl::Image& inImage,
 const float inAppendedChannelValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inAppendedChannelValue	const float		
←	outImage	Image&		Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input image cannot have 4 channels in AppendImageChannel.

AverageChannels

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image by averaging the input image channels.

Syntax

```
void avl::AverageChannels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

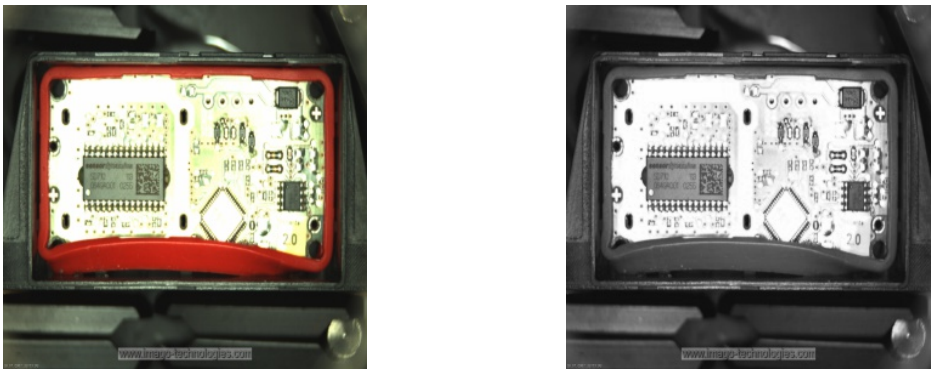
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Description

The operation computes the monochromatic average of **inImage** color channels. Average being computed at each pixel is a standard arithmetic mean.

Examples



AverageChannels *run on example image.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 3xUINT8.

This operation is optimized for SSSE3 technology for pixels of types: 2xUINT8, 4xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AverageChannels.

See Also

- AverageChannels_Weighted – Creates a monochromatic image from weighted averages of the input image channels.

AverageChannels_121

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image by averaging the input image channels.

Applications: Conversion to mono which is more consistent with human perception (our eyes are more sensitive to green).

Syntax

```
void avl::AverageChannels_121
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Description

The operation computes the monochromatic average of **inImage** color channels. Average being computed at each pixel is a mean with weight (1, 2, 1).

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

This operation is optimized for AVX2 technology for pixels of type: 3xUINT8.

This operation is optimized for NEON technology for pixels of type: 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AverageChannels_121.
DomainError	Not supported inImage pixel format in AverageChannels_121. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

See Also

- AverageChannels_Weighted – Creates a monochromatic image from weighted averages of the input image channels.
- AverageChannels – Creates a monochromatic image by averaging the input image channels.

AverageChannels_251

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image by averaging the input image channels.

Applications: Conversion to mono which is more consistent with human perception (our eyes are more sensitive to green).

Syntax

```
void avl::AverageChannels_251
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 3×uint8, 3×int8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

This operation is optimized for AVX2 technology for pixels of type: 3xUINT8.

This operation is optimized for NEON technology for pixels of type: 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in AverageChannels_251.
DomainError	Not supported inImage pixel format in AverageChannels_251. Supported formats: 3xUInt8, 3xInt8.

Also in AVL Lite

AverageChannels_Weighted

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a monochromatic image from weighted averages of the input image channels.

Syntax

```
void avl::AverageChannels_Weighted
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 int inWeight1,
 int inWeight2,
 int inWeight3,
 int inWeight4,
 avl::Image& outImage
)
```

Parameters

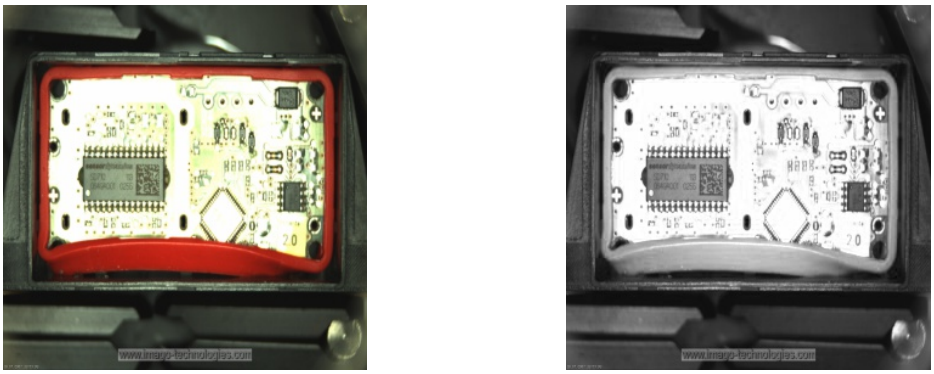
	Name	Type	Default	Description
➡	inImage	const Image&		Input image
➡	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
➡	inWeight1	int		Weight of the first channel
➡	inWeight2	int		Weight of the second channel
➡	inWeight3	int		Weight of the third channel
➡	inWeight4	int		Weight of the fourth channel
⬅	outImage	Image&		Output image

Description

The operation computes the monochromatic average of the **inImage** color channels. Average being computed at each pixel is a weighted arithmetic mean.

Weights of the channels are determined by the parameters **inWeight1**, **inWeight2**, **inWeight3**, **inWeight4**. For images having less than four channels, it is required that weights assigned to non-existing channels equal zero.

Examples



AverageChannels_Weighted *run on example image with* ***inWeight1*** *= 1,* ***inWeight2*** *= 0,* ***inWeight3*** *= 0,* ***inWeight4*** *= 0, which for a RGB image is equivalent to the extraction of the Red channel.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Non-zero weight of not existing image channel in AverageChannels_Weighted.
DomainError	Region exceeds an input image in AverageChannels_Weighted.
DomainError	Sum of weights equals zero in AverageChannels_Weighted.

See Also

- AverageChannels – Creates a monochromatic image by averaging the input image channels.
- MixChannels – Calculates a linear combination of image channels.

ConvertPixelType

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the type of pixel components.

Syntax

```
void avl::ConvertPixelType
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::PlainType::Type inNewType,
 int inDepthDelta,
 avl::Image& outImage
)
```

Parameters

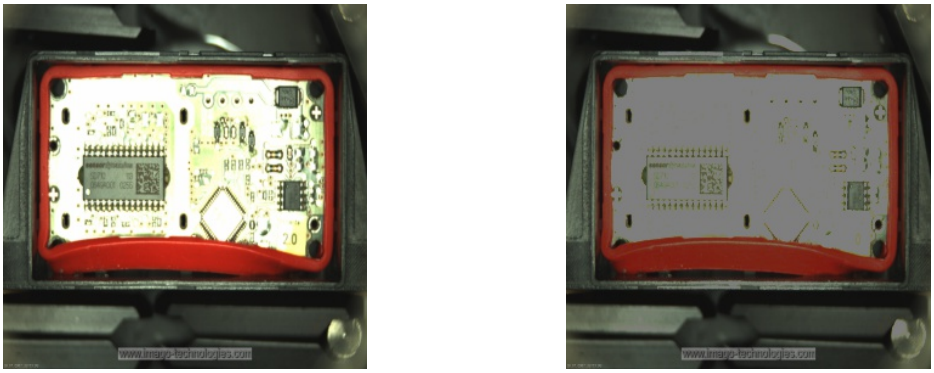
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inNewType	PlainType::Type		UInt8	Type of the output image
→	inDepthDelta	int	-30 – 30	0	Pixel values will be multiplied by 2^inDepthDelta. For example, use -4 to convert 12-bit to 8-bit images.
←	outImage	Image&			Output image

Description

The operation alters the pixel component format of the **inImage**. Available formats are listed in the documentation of the Image data type.

If the value of pixel component doesn't fit in the range of the new type, it is clipped to the nearest proper value, which can lead to the significant loss of information, as demonstrated in the example.

Examples



ConvertPixelType *run on example image of UInt8 type with* ***inNewType*** *being Int8. Note that bright pixels suffered from clipping, while dark ones remained unaltered.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE2 technology for pixels of types: UINT16 (when converting to UINT8 with negative delta).

This operation is optimized for AVX2 technology for pixels of types: UINT16 (when converting to UINT8 with negative delta).

This operation is optimized for NEON technology for pixels of types: UINT16 (when converting to UINT8 with negative delta).

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ConvertPixelType.

ConvertToMultichannel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a multichannel image from a monochromatic one by replicating its channel.

Syntax

```
void avl::ConvertToMultichannel
(
 const avl::Image& inMonoImage,
 atl::Optional<const avl::Region&> inRoi,
 int inNewDepth,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMonoImage	const Image&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inNewDepth	int	1 – 4	3	
←	outImage	Image&			Output image

Description

The operation computes multichannel image equivalent to monochromatic **inMonoImage**. The number of channels in the resulting image is determined by the **inNewDepth** parameter. Each of the channels in **outImage** will be equal to the only channel of the **inMonoImage**.

Note that the operation does not alter the appearance of the image in the IDE.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of types: 3xUINT8, 3xSINT8, 3xUINT16, 3xSINT16, 3xSINT32, 3xREAL.

This operation is optimized for NEON technology for pixels of types: 3xUINT8, 3xSINT8, 3xUINT16, 3xSINT16, 3xSINT32, 3xREAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a monochromatic input in ConvertToMultichannel.
DomainError	Region exceeds an input image in ConvertToMultichannel.

MaxChannels

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a monochromatic image by taking the maximum value of all the input image channels.

Syntax

```
void avl::MaxChannels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		output mono image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 2xUINT8.

This operation is optimized for SSSE3 technology for pixels of types: 3xUINT8, 4xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in MaxChannels.

Also in AVL Lite

MergeChannels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a multichannel image from several monochromatic ones.

Syntax

```
void avl::MergeChannels
(
 const avl::Image& inMonoImage1,
 const avl::Image& inMonoImage2,
 atl::Optional<const avl::Image&> inMonoImage3,
 atl::Optional<const avl::Image&> inMonoImage4,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inMonoImage1	const Image&		An image that becomes the first channel
→	inMonoImage2	const Image&		An image that becomes the second channel
→	inMonoImage3	Optional<const Image&>	NIL	An image that becomes the third channel
→	inMonoImage4	Optional<const Image&>	NIL	An image that becomes the fourth channel
←	outImage	Image&		Output image

Requirements

For input **inMonoImage1** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

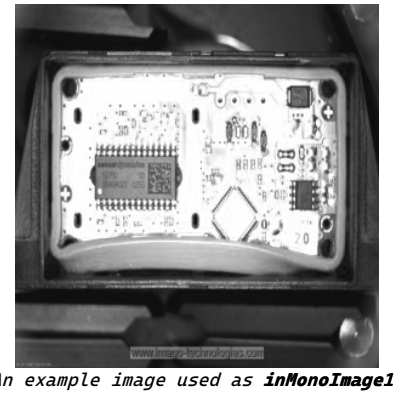
For input **inMonoImage2** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

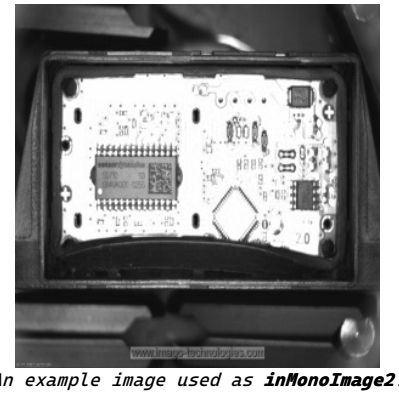
Description

The operation combines the given monochromatic images to obtain a color image, each of its channels equal to the only channel of the corresponding input image.

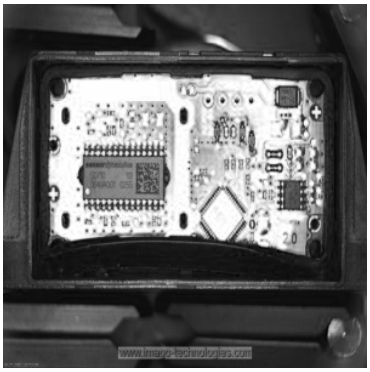
Examples



*An example image used as **inMonoImage1**.*



*An example image used as **inMonoImage2**.*



*An example image used as **inMonoImage3**.*

*The resulting **outImage**.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image sizes are not equal in MergeChannels.
DomainError	Input image is not monochromatic in MergeChannels.
DomainError	Pixel types of the input images are not the same in MergeChannels.
DomainError	Not supported inMonoImage1 pixel format in MergeChannels. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.
DomainError	Not supported inMonoImage2 pixel format in MergeChannels. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

See Also

- SplitChannels – Creates several monochromatic images from individual channels of the input image.

MinChannels

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a monochromatic image by taking the minimum value of all the input image channels.

Syntax

```
void avl::MinChannels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		output mono image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 2xUINT8.

This operation is optimized for SSSE3 technology for pixels of types: 3xUINT8, 4xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 2xUINT8, 3xUINT8, 4xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in MinChannels.

MixChannels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Calculates a linear combination of image channels.

Syntax

```
void avl::MixChannels
(
 const avl::Image& inImage,
 int inXCoeff,
 int inYCoeff,
 int inZCoeff,
 int inWCoeff,
 int inDivider,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inXCoeff	int			
→	inYCoeff	int			
→	inZCoeff	int			
→	inWCoeff	int			
→	inDivider	int	1 – ∞		
←	outImage	Image&			Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

RemoveChannel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image by removing a single channel from the input image.

Syntax

```
void avl::RemoveChannel
(
 const avl::Image& inImage,
 int inChannelIndex,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inChannelIndex	int	0 – 3		
←	outImage	Image&			Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel cannot be removed from single-channel image in RemoveChannel.
DomainError	Channel index out of range in RemoveChannel.

ReverseChannels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reverses the order of channels in an image.

Applications: E.g. when one has an RGB image, but needs to convert to BGR.

Syntax

```
void avl::ReverseChannels
(
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

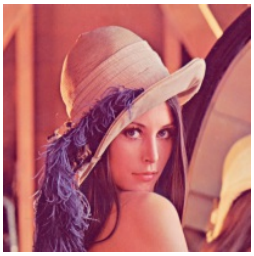
	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImage	Image&		Output image with reversed channels

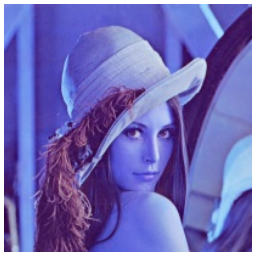
In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Examples





Channels reversed from RGB to BGR on the Lena image.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- SelectChannel - Creates an image from a single channel of the input image.
- MergeChannels - Creates a multichannel image from several monochromatic ones.

SelectChannel

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image from a single channel of the input image.

Syntax

```
void avl::SelectChannel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 int inChannelIndex,
 avl::Image& outImage
)
```

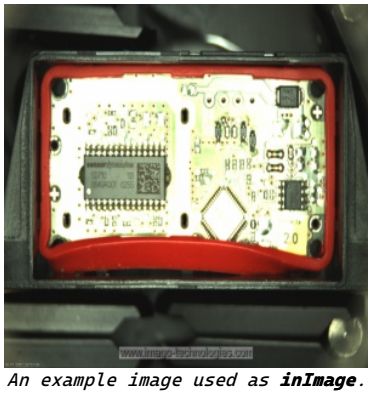
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inChannelIndex	int	0 – 3		
←	outImage	Image&			Output image

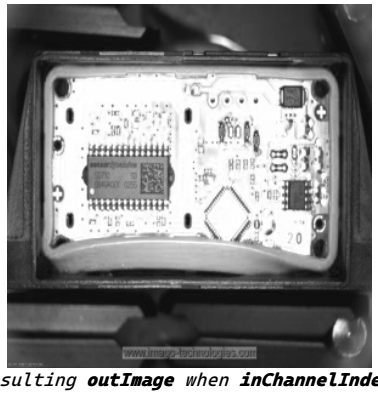
Description

The operation extracts the selected color channel of **inImage**.

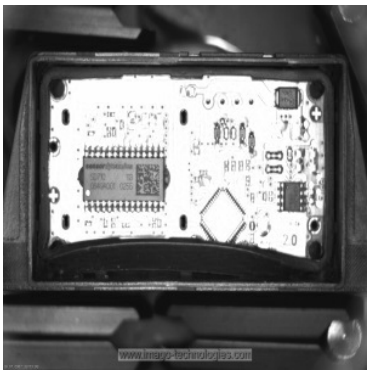
Examples



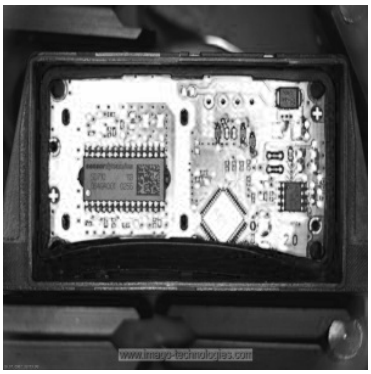
*An example image used as **inImage**.*



*The resulting **outImage** when **inChannelIndex** = 0.*



*The resulting **outImage** when **inChannelIndex** = 1.*



*The resulting **outImage** when **inChannelIndex** = 2.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index out of range in SelectChannel.
DomainError	Region exceeds an input image in SelectChannel.

See Also

- SplitChannels – Creates several monochromatic images from individual channels of the input image.

SplitChannels

Also in **AVL Lite**

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates several monochromatic images from individual channels of the input image.

Syntax

```
void avl::SplitChannels
(
 const avl::Image& inImage,
 atl::Optional<avl::Image&> outMonoImage1 = atl::NIL,
 atl::Optional<avl::Image&> outMonoImage2 = atl::NIL,
 atl::Optional<avl::Image&> outMonoImage3 = atl::NIL,
 atl::Optional<avl::Image&> outMonoImage4 = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outMonoImage1	Optional<Image&>	NIL	Image of the first channel
←	outMonoImage2	Optional<Image&>	NIL	Image of the second channel (if exists)
←	outMonoImage3	Optional<Image&>	NIL	Image of the third channel (if exists)
←	outMonoImage4	Optional<Image&>	NIL	Image of the fourth channel (if exists)

Optional Outputs

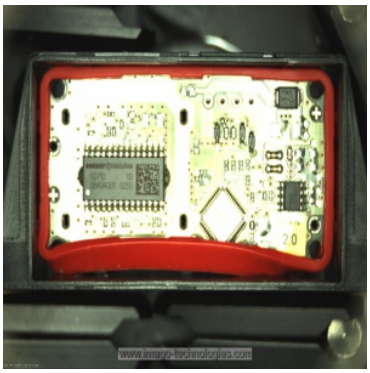
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMonoImage1**, **outMonoImage2**, **outMonoImage3**, **outMonoImage4**.

Read more about Optional Outputs.

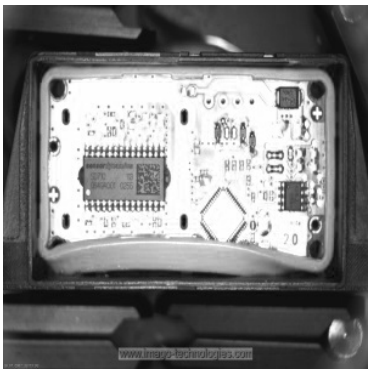
Description

The operation extracts the color channels of **inImage** as separate monochromatic images. Outputs corresponding to non-existing channels of an image are set to empty images.

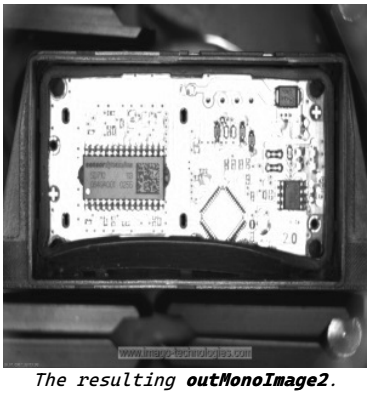
Examples



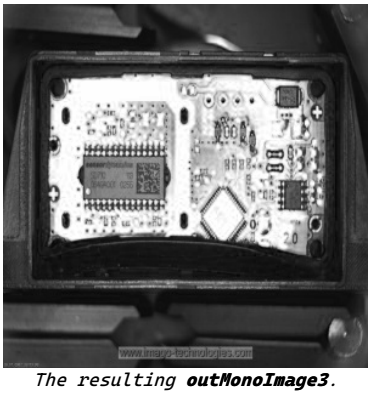
*An example image used as **inImage**.*



*The resulting **outMonoImage1**.*



*The resulting **outMonoImage2**.*



*The resulting **outMonoImage3**.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- SelectChannel – Creates an image from a single channel of the input image.
- MergeChannels – Creates a multichannel image from several monochromatic ones.
- SplitChannels_OrNil – Creates several monochromatic images from individual channels of the input image and sets Nil for channels that are not present.

SplitChannels_OrNil

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates several monochromatic images from individual channels of the input image and sets Nil for channels that are not present.

Syntax

```
void avl::SplitChannels_OrNil
(
 const avl::Image& inImage,
 atl::Optional<atl::Conditional<avl::Image>&> outMonoImage1 = atl::NIL,
 atl::Optional<atl::Conditional<avl::Image>&> outMonoImage2 = atl::NIL,
 atl::Optional<atl::Conditional<avl::Image>&> outMonoImage3 = atl::NIL,
 atl::Optional<atl::Conditional<avl::Image>&> outMonoImage4 = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outMonoImage1	Optional<Conditional<Image>&>	NIL	Image of the first channel
←	outMonoImage2	Optional<Conditional<Image>&>	NIL	Image of the second channel (if exists)
←	outMonoImage3	Optional<Conditional<Image>&>	NIL	Image of the third channel (if exists)
←	outMonoImage4	Optional<Conditional<Image>&>	NIL	Image of the fourth channel (if exists)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMonoImage1**, **outMonoImage2**, **outMonoImage3**, **outMonoImage4**.

Read more about Optional Outputs.

Description

The operation extracts the color channels of **inImage** as separate monochromatic images. Outputs corresponding to non-existing channels of an image are set to Nil.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

AddHistograms

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Adds two histograms bar by bar.

Syntax

```
void avl::AddHistograms
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the sum of two histograms. That is, each bin of the resulting histogram equals the sum of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in AddHistograms.

AddHistograms_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Adds histograms of an array bar by bar.

Syntax

```
void avl::AddHistograms_OfArray
(
 const atl::Array<avl::Histogram>& inHistogramArray,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogramArray	const Array<Histogram>&		
←	outHistogram	Histogram&		Output histogram

Description

Array version of AddHistograms.

See Also

- AddHistograms – Adds two histograms bar by bar.

AddHistograms_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Adds histograms appearing in consecutive iterations bar by bar.

Syntax

```
void avl::AddHistograms_OfLoop
(
 HistogramCombinators_OfLoopState& ioState,
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	HistogramCombinators_OfLoopState&		Object used to maintain state of the function.
→	inHistogram	const Histogram&		Input histogram
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

Description

Loop version of AddHistograms.

See Also

- AddHistograms – Adds two histograms bar by bar.

DifferenceHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes histogram representing difference between corresponding bars of given histograms.

Syntax

```
void avl::DifferenceHistogram
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the absolute difference between histograms. That is, each bin of the resulting histogram equals the absolute value of difference between corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in DifferenceHistogram.

DivideHistograms

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Divides two histograms bar by bar.

Syntax

```
void avl::DivideHistograms
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the quotient of two histograms. That is, each bin of the resulting histogram equals the quotient of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in DivideHistograms.
DomainError	One of inHistogram2 bins equals zero in DivideHistograms.

MaximumHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the maximum of two histograms bar by bar.

Syntax

```
void avl::MaximumHistogram
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the maximum of two histograms. That is, each bin of the resulting histogram equals the maximum of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in MaximumHistogram.

MaximumHistogram_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the maximum of histograms of an array bar by bar.

Syntax

```
void avl::MaximumHistogram_OfArray
(
 const atl::Array<avl::Histogram>& inHistogramArray,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogramArray	const Array<Histogram>&		
←	outHistogram	Histogram&		Output histogram

Description

Array version of MaximumHistogram.

See Also

- MaximumHistogram – Computes the maximum of two histograms bar by bar.

MaximumHistogram_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the maximum of histograms appearing in consecutive iterations bar by bar.

Syntax

```
void avl::MaximumHistogram_OfLoop
(
 HistogramCombinators_OfLoopState& ioState,
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	HistogramCombinators_OfLoopState&		Object used to maintain state of the function.
→	inHistogram	const Histogram&		Input histogram
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

Description

Loop version of MaximumHistogram.

See Also

- MaximumHistogram – Computes the maximum of two histograms bar by bar.

MinimumHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the minimum of two histograms bar by bar.

Syntax

```
void avl::MinimumHistogram
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the minimum of two histograms. That is, each bin of the resulting histogram equals the minimum of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in MinimumHistogram.

MinimumHistogram_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the minimum of histograms of an array bar by bar.

Syntax

```
void avl::MinimumHistogram_OfArray
(
 const atl::Array<avl::Histogram>& inHistogramArray,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogramArray	const Array<Histogram>&		
←	outHistogram	Histogram&		Output histogram

Description

Array version of MinimumHistogram.

See Also

- MinimumHistogram – Computes the minimum of two histograms bar by bar.

MinimumHistogram_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the minimum of histograms appearing in consecutive iterations bar by bar.

Syntax

```
void avl::MinimumHistogram_OfLoop
(
 HistogramCombinators_OfLoopState& ioState,
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	HistogramCombinators_OfLoopState&		Object used to maintain state of the function.
→	inHistogram	const Histogram&		Input histogram
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

Description

Loop version of MinimumHistogram.

See Also

- MinimumHistogram – Computes the minimum of two histograms bar by bar.

MultiplyHistograms

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Multiplies two histograms bar by bar.

Syntax

```
void avl::MultiplyHistograms
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation computes the product of two histograms. That is, each bin of the resulting histogram equals the product of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in MultiplyHistograms.

MultiplyHistograms_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Multiply histograms of an array bar by bar.

Syntax

```
void avl::MultiplyHistograms_OfArray
(
 const atl::Array<avl::Histogram>& inHistogramArray,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogramArray	const Array<Histogram>&		
←	outHistogram	Histogram&		Output histogram

Description

Array version of MultiplyHistograms.

See Also

- MultiplyHistograms – Multiplies two histograms bar by bar.

MultiplyHistograms_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Multiply histograms appearing in consecutive iterations bar by bar.

Syntax

```
void avl::MultiplyHistograms_OfLoop
(
 HistogramCombinators_OfLoopState& ioState,
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	HistogramCombinators_OfLoopState&		Object used to maintain state of the function.
→	inHistogram	const Histogram&		Input histogram
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

Description

Loop version of MultiplyHistograms.

See Also

- MultiplyHistograms – Multiplies two histograms bar by bar.

SubtractHistograms

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Subtracts two histograms bar by bar.

Syntax

```
void avl::SubtractHistograms
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		Input histogram1
→	inHistogram2	const Histogram&		Input histogram2
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram1** and **outHistogram**, **inHistogram2** and **outHistogram**

Read more about In-place Computation.

Description

The operation subtracts two histograms. That is, each bin of the resulting histogram equals the difference of corresponding bins of the input histograms.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in SubtractHistograms.

AddImages

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds two images pixel by pixel.

Syntax

```
void avl::AddImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	Output image scaling factor
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

The operation computes the sum of two images. Each **outImage** pixel is equal to the sum of the corresponding pixels of the input images.

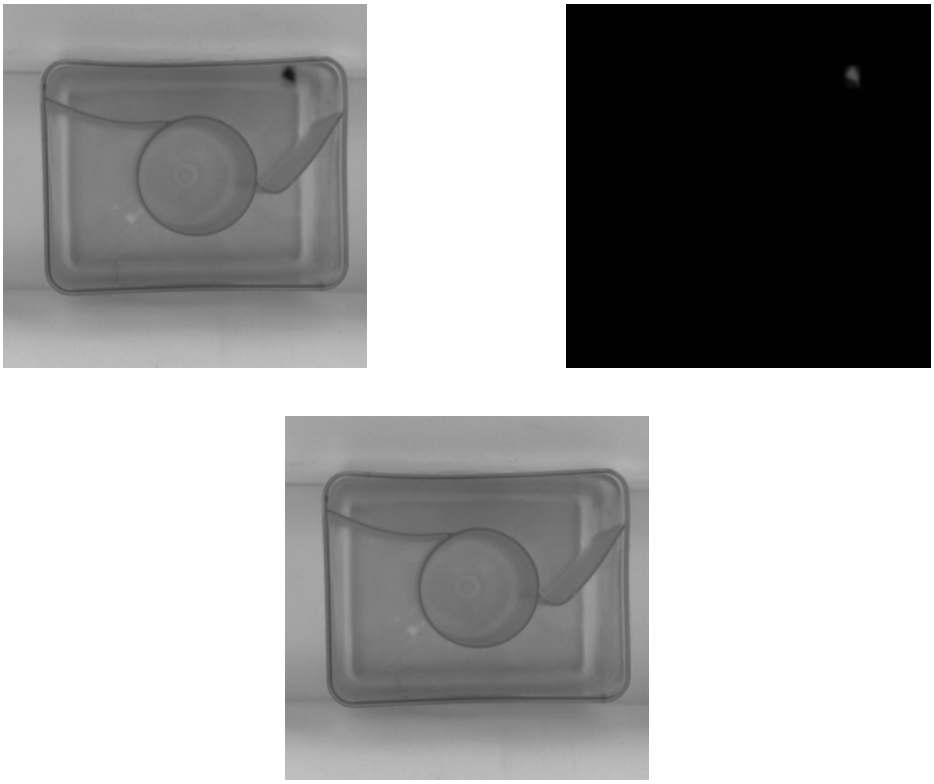
$$\forall_{i,j} \mathrm{OutImage}_{i,j} = (\mathrm{InImage1}_{i,j} + \mathrm{InImage2}_{i,j}) \cdot \mathrm{InScale}$$

The result of the operation is multiplied by **inScale** factor, which may be used to avoid clipping when the produced values exceed the range of correct pixel values. However it should be noted that when the value of **inScale** is other than 1.0, the filter uses a slower, not SSE-optimized implementation.

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples



AddImages *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL, SINT8(for inScale=1), UINT16(for inScale=1).

This operation is optimized for SSE41 technology for pixels of types: UINT16(for inScale!=1).

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, SINT16, UINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, REAL(for inScale!=1), SINT32(for inScale!=1).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in AddImages.
DomainError	Image sizes are not equal in AddImages.
DomainError	Region exceeds an input image in AddImages.

See Also

AddImages_OfArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds images of an array pixel by pixel.

Syntax

```
void avl::AddImages_OfArray
(
 const atl::Array<avl::Image>& inImageArray,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImageArray	const Array<Image>&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	
←	outImage	Image&		Output image

Description

Array version of AddImages.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, SINT16, REAL, SINT8(for inScale=1), UINT16(for inScale=1).

AddImages_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds images appearing in consecutive iterations pixel by pixel.

Syntax

```
void avl::AddImages_OfLoop
(
 ImageCombinators_OfLoopState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	ImageCombinators_OfLoopState&		Object used to maintain state of the function.
	inImage	const Image&		Input image
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	inScale	float	1.0f	
	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Also in AVL Lite

AverageImages

Header: AVL.h
Namespace: avl
Module: FoundationLite

Averages two images pixel by pixel.

Syntax

```
void avl::AverageImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

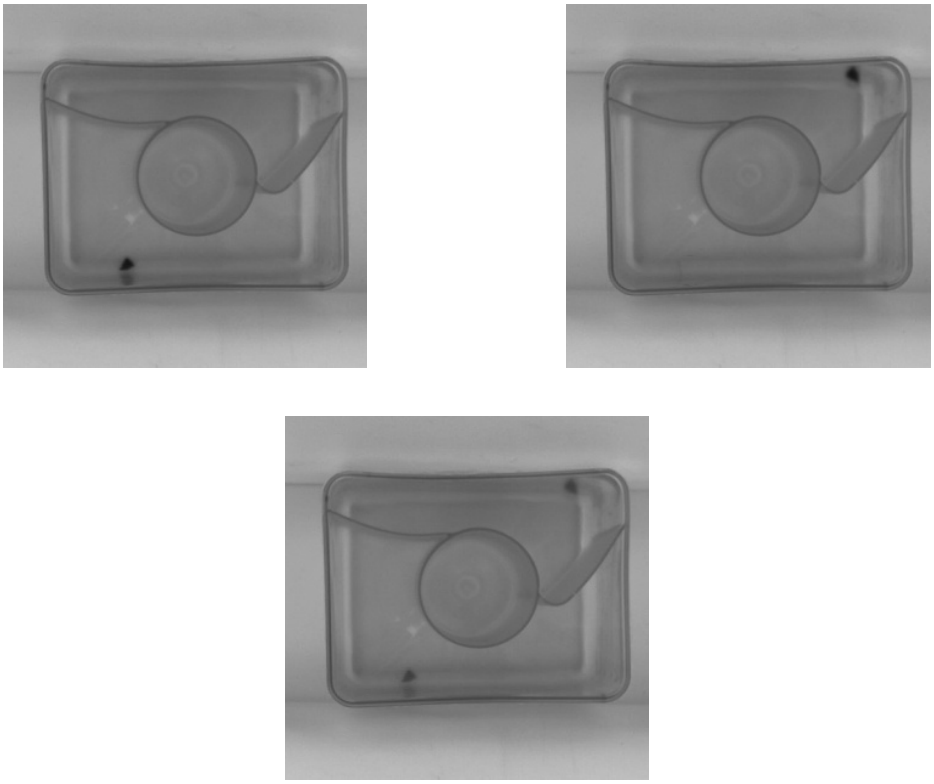
The operation computes the average of two images. Each **outImage** pixel is equal to the average of the corresponding pixels of the input images.

$$\forall_{i,j}\mathbf{OutImage}_{i,j} = \frac{\mathbf{InImage1}_{i,j} + \mathbf{InImage2}_{i,j}}{2}$$

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples



AverageImages *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, UINT16, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in AverageImages.
DomainError	Image sizes are not equal in AverageImages.
DomainError	Region exceeds an input image in AverageImages.

See Also

- BlendImages – Computes weighted sum pixel by pixel.

AverageImages_OfArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Averages images from an array pixel by pixel.

Syntax

```
void avl::AverageImages_OfArray
(
 const atl::Array<avl::Image>& inImages,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImages	const Array<Image>&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Description

Array version of AverageImages.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of images in AverageImages_OfArray.
DomainError	Image dimensions are not equal in AverageImages_OfArray.
DomainError	Image formats are not the same in AverageImages_OfArray.
DomainError	Not supported image type in AverageImages_OfArray.
DomainError	Region exceeds an input image in AverageImages_OfArray.

See Also

- AverageImages – Averages two images pixel by pixel.

AverageImages_OfLoop

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Averages images appearing in consecutive iterations pixel by pixel.

Syntax

```
void avl::AverageImages_OfLoop
(
 AverageImages_OfLoopState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Image&> outImage
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AverageImages_OfLoopState&		Object used to maintain state of the function.
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Optional<Image&>		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outImage**.

Read more about Optional Outputs.

Description

Loop version of AverageImages.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image dimensions are not equal in AverageImages_OfLoop.
DomainError	Image formats are not the same in AverageImages_OfLoop.
DomainError	Region exceeds an input image in AverageImages_OfLoop.

See Also

- AverageImages - Averages two images pixel by pixel.

BlendImages

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes weighted sum pixel by pixel.

Syntax

```
void avl::BlendImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inAmount1,
 float inAmount2,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inAmount1	float	$-\infty$ – ∞	0.5f	
→	inAmount2	float	$-\infty$ – ∞	0.5f	
←	outImage	Image&			Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

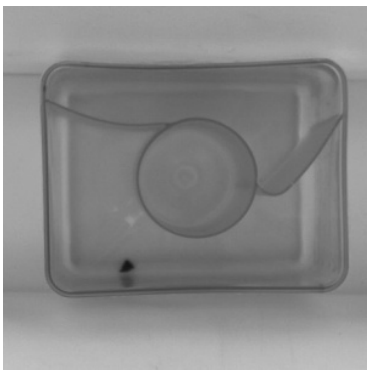
The operation computes the weighted sum of the corresponding pixels of the input images. Note that the sum of selected weight need not to equal 1.0, but only when the sum is less or equal to 1.0 the resulting value is guaranteed to fit in the range of pixel values.

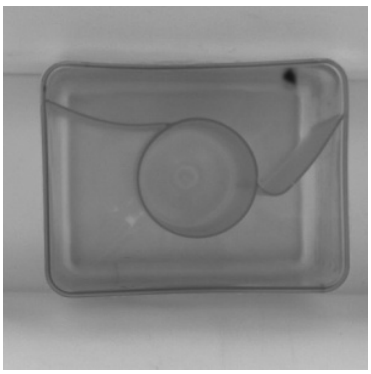
$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \mathrm{InAmount1} \cdot \mathrm{InImage1}_{i,j} + \mathrm{InAmount2} \cdot \mathrm{InImage2}_{i,j}$$

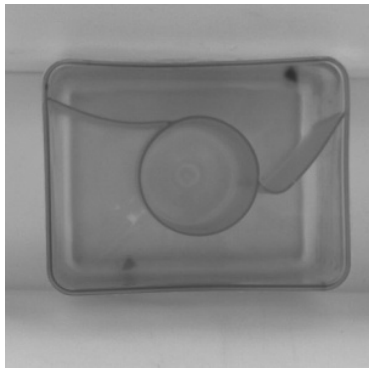
Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples







BlendImages *performed on the sample images with* ***inAmount1*** *= 0.3,* ***inAmount2*** *= 0.7.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in BlendImages.
DomainError	Image sizes are not equal in BlendImages.
DomainError	Region exceeds an input image in BlendImages.

See Also

- AverageImages – Averages two images pixel by pixel.
- LerpImages – Interpolates two images linearly pixel by pixel.

Also in **AVL Lite**

ComposeImages

Header: AVL.h
Namespace: avl
Module: FoundationLite

Takes pixels from the first image within the specified region and from the other one elsewhere.

Syntax

```
void avl::ComposeImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 const avl::Region& inRegion,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First source of pixels marked in inRegion
→	inImage2	const Image&		Background image
→	inRegion	const Region&		Region which describes which pixels should be taken from inImage1
→	inRoi	Optional<const Region&>	NIL	Region in which pixels should be processed otherwise black pixels are placed
←	outImage	Image&		Image composed of tho input images

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

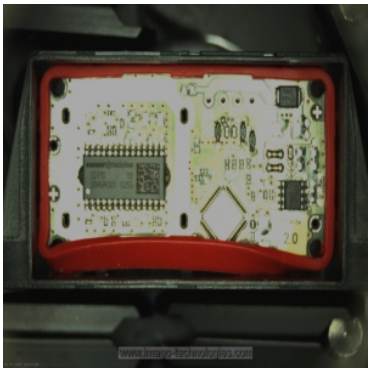
Description

The operation computes the composition of two images. Each **outImage** pixel is equal to the corresponding pixel of **inImage1** iff its location lies inside the **inRegion**; otherwise the pixel is equal to the corresponding pixel of the **inImage2**.

$$\forall_{i,j}\mathbf{OutImage}_{i,j} = \begin{cases} \mathbf{InImage1}_{i,j} & \text{if } (i,j) \in \mathbf{InRegion} \\ \mathbf{InImage2}_{i,j} & \text{otherwise} \end{cases}$$

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples



*Example **inImage1** and **inImage2**.*

*Example **inRegion** and the result of **ComposeImages***

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in ComposeImages.
DomainError	Image sizes are not equal in ComposeImages.
DomainError	Input region exceeds an input image in ComposeImages.
DomainError	Input ROI exceeds an input image in ComposeImages.

See Also

- JoinImages – Creates a single image by glueing together the two input images in horizontal or vertical direction.
- DrawGridImage – Draws an image as a tile on an image considered to be a grid of tiles.

CorrectFlatField

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs flat-field correction on an image to compensate for non-uniform sensor response and illumination.

Applications: Shading correction, vignetting removal, line-scan camera calibration.

Syntax

```
void avl::CorrectFlatField
(
 const avl::Image& inImage,
 const avl::Image& inFlatField,
 atl::Optional<const avl::Image&> inDarkFrame,
 atl::Optional<const avl::Region&> inRoi,
 float inOutputMaxValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Raw captured image
→	inFlatField	const Image&		Averaged flat-field reference image
→	inDarkFrame	Optional<const Image&>	NIL	Averaged dark frame; when set, dark signal is subtracted from both images before division
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inOutputMaxValue	float	255.0f	Target white level after correction (e.g. 255 for UInt8)
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Image and dark frame formats are not the same in CorrectFlatField.
DomainError	Image and dark frame sizes are not equal in CorrectFlatField.
DomainError	Image and flat-field formats are not the same in CorrectFlatField.
DomainError	Image and flat-field sizes are not equal in CorrectFlatField.
DomainError	Region exceeds an input image in CorrectFlatField.

DifferenceImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the non-negative distances between corresponding pixel values.

Applications: Useful for things like comparing an image against a template or for detecting differences between consecutive video frames.

Syntax

```
void avl::DifferenceImage
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

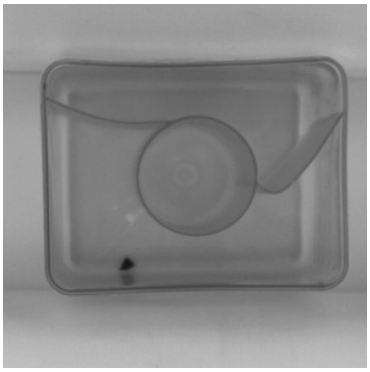
The operation computes the absolute difference between images. Each **outImage** pixel is equal to the absolute value of difference between corresponding pixels of the input images.

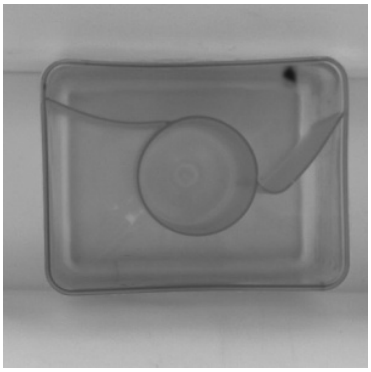
$$\forall_{i,j} \mathbf{OutImage}_{i,j} = |\mathbf{InImage1}_{i,j} - \mathbf{InImage2}_{i,j}|$$

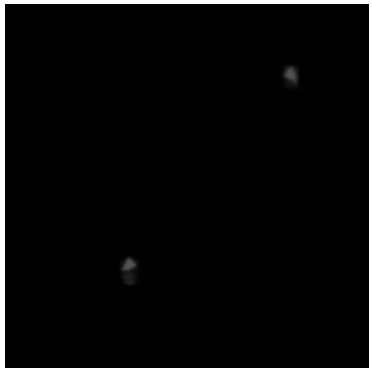
In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples







DifferenceImage *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in DifferenceImage.
DomainError	Image sizes are not equal in DifferenceImage.
DomainError	Region exceeds an input image in DifferenceImage.

DifferenceImage_Flex

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the non-negative distances between corresponding pixel values using tiles.

Applications: Useful for things like comparing an image against a template or for detecting differences between consecutive video frames.

Syntax

```
void avl::DifferenceImage_Flex
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Box&> inBox1,
 atl::Optional<const avl::Box&> inBox2,
 int inTileWidth,
 atl::Optional<int> inTileHeight,
 avl::TileTranslationMode::Type inTileTranslationMode,
 const bool inOutputFromColorImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inBox1	Optional<const Box&>		NIL	
→	inBox2	Optional<const Box&>		NIL	
→	inTileWidth	int	1 – ∞	16	
→	inTileHeight	Optional<int>	1 – ∞	NIL	
→	inTileTranslationMode	TileTranslationMode::Type		FourDirections	
→	inOutputFromColorImage	const bool		False	Flag indicating whether to use every channel of the input images separately to compute results or only channels average
←	outImage	Image&			Output image

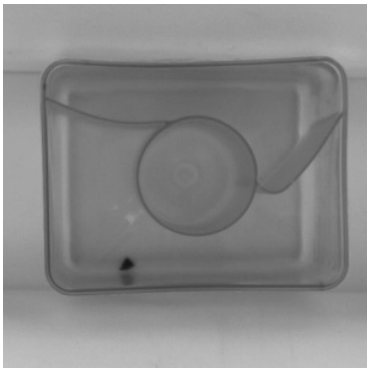
Description

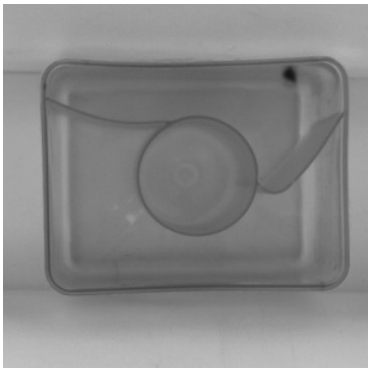
The operation computes the absolute difference between images. First the input images are divided into tiles. Each tile is then considered separately. It is translated by a minimal vector in one of the number of directions (depending on **inTileTranslationMode**, 4 or 8) and the translation with minimum overall difference between input images in this tile is considered to be the proper one. Finally, the output image values in the tile are computed using the so computed translation and the same formula like in DifferenceImage_Shifted.

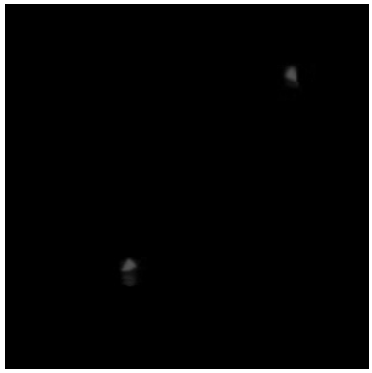
In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples







*DifferenceImage_Flex performed on the sample images with **inTileWidth** = **inTileHeight** = 16 and **inTileTranslationMode** = EightDirections.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in DifferenceImage_Flex.
DomainError	Image fragments dimensions are not equal in DifferenceImage_Flex.
DomainError	Input box exceeds image dimensions in DifferenceImage_Flex.

See Also

- SubtractImages – Subtracts two images pixel by pixel.

Also in AVL Lite

DifferenceImage_Shifted

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the non-negative distances between corresponding pixel values.

Applications: Useful for things like comparing an image against a template or for detecting differences between consecutive video frames.

Syntax

```
void avl::DifferenceImage_Shifted
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 const avl::Box& inBox1,
 const avl::Box& inBox2,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
➡	inImage1	const Image&		First input image
➡	inImage2	const Image&		Second input image
➡	inBox1	const Box&		
➡	inBox2	const Box&		
⬅	outImage	Image&		Output image

Description

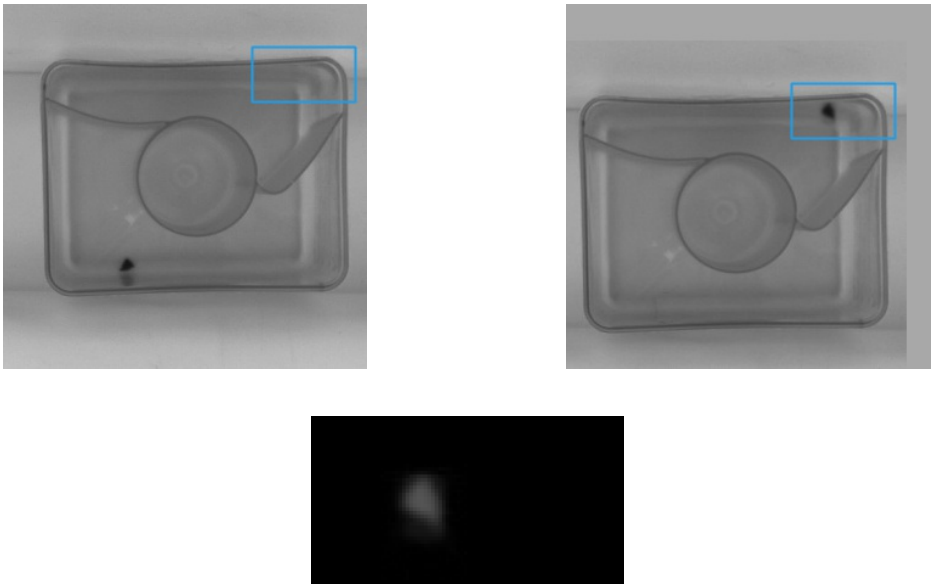
The operation computes the absolute difference between image pixels inside the input boxes. Each **outImage** pixel is equal to the absolute value of difference between corresponding pixels of the input images:

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = |\mathrm{InImage1}_{i+box1.x,j+box1.y} - \mathrm{InImage2}_{i+box2.x,j+box2.y}|$$

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and the input boxes have equal dimensions, otherwise an error with appropriate description occurs. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples



DifferenceImage_Shifted *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in DifferenceImage_Shifted.
DomainError	Input boxes are not completely inside the input images in DifferenceImage_Shifted.
DomainError	Not equal box dimensions in DifferenceImage_Shifted.

See Also

- SubtractImages – Subtracts two images pixel by pixel.

DivideImages

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Divides two images pixel by pixel.

Applications: Can be used for flat field correction.

Syntax

```
void avl::DivideImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	Output image scaling factor
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

The operation computes the quotient of two images. Each **outImage** pixel is equal to the quotient of the corresponding pixels of the input images.

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \left(\frac{\mathrm{InImage1}_{i,j}}{\mathrm{InImage2}_{i,j}} \right) \cdot \mathrm{InScale}$$

The result of the operation is multiplied by **inScale** factor, which may be used to avoid clipping when the produced values exceed the range of correct pixel values. However it should be noted that when the value of **inScale** is other than 1.0, the filter uses a slower, not SSE-optimized implementation.

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE41 technology for pixels of type: UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, UINT16, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32(for inScale!=1), REAL(for inScale!=1).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in DivideImages.
DomainError	Image sizes are not equal in DivideImages.
DomainError	Region exceeds an input image in DivideImages.

See Also

- MultiplyImages – Multiplies two images pixel by pixel.

LerpImages

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Interpolates two images linearly pixel by pixel.

Syntax

```
void avl::LerpImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inLambda,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inLambda	float	0.0 – 1.0	0.5f	Interpolation between the input images where 0.0 value is equal to inImage1 and 1.0 to inImage2
←	outImage	Image&			Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

The operation computes the linear interpolation of two images. Each pixel of the output image is computed as follows.

$$outImage[i,j] = (1 - inLambda) \cdot inImage0[i,j] + inLambda \cdot inImage1[i,j]$$

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in LerpImages.
DomainError	Image sizes are not equal in LerpImages.
DomainError	Region exceeds an input image in LerpImages.

See Also

- AverageImages – Averages two images pixel by pixel.
- BlendImages – Computes weighted sum pixel by pixel.

LerpImages_ByImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Interpolates two images linearly pixel by pixel according to another image values.

Syntax

```
void avl::LerpImages_ByImage
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Image& inLambdaImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inLambdaImage	const Image&		Values of interpolation between the input images where 0.0 value is equal to inImage1 and 1.0 to inImage2
←	outImage	Image&		Output image

Requirements

For input **inLambdaImage** only pixel formats are supported: 1×real.

Read more about pixel formats in Image documentation.

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in LerpImages_ByImage.
DomainError	Image sizes are not equal in LerpImages_ByImage.
DomainError	Region exceeds an input image in LerpImages_ByImage.
DomainError	Not supported inLambdaImage pixel format in LerpImages_ByImage. Supported formats: 1xReal.

MaximumImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image from the higher pixel values of each corresponding pair.

Syntax

```
void avl::MaximumImage
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

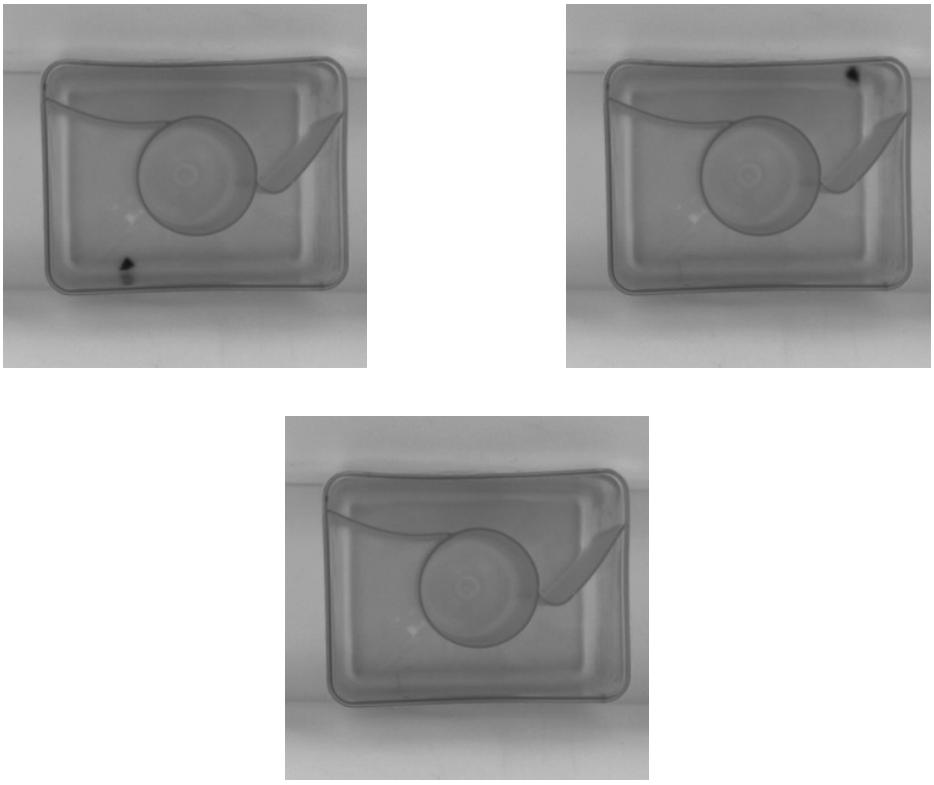
The operation computes the maximum of two images. Each **outImage** pixel is equal to the brighter of the corresponding pixels of the input images.

$$\forall_{i,j} \mathbf{OutImage}_{i,j} = \mathrm{Max}(\mathbf{InImage1}_{i,j}, \mathbf{InImage2}_{i,j})$$

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples



MaximumImage *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE4.1 technology for pixels of types: SINT8, UINT16, SINT32.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in MaximumImage.
DomainError	Image sizes are not equal in MaximumImage.
DomainError	Region exceeds an input image in MaximumImage.

See Also

- MinimumImage – Creates an image from the lower pixel values of each corresponding pair.

Also in AVL Lite

MaximumImage_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the maximum of images of an array pixel by pixel.

Syntax

```
void avl::MaximumImage_OfArray
(
 const atl::Array<avl::Image>& inImageArray,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImageArray	const Array<Image>&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Description

Array version of MaximumImage.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE4.1 technology for pixels of types: SINT8, UINT16, SINT32.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- MaximumImage – Creates an image from the higher pixel values of each corresponding pair.

MaximumImage_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the maximum of images appearing in consecutive iterations pixel by pixel.

Syntax

```
void avl::MaximumImage_OfLoop
(
 ImageCombinators_OfLoopState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	ImageCombinators_OfLoopState&		Object used to maintain state of the function.
	inImage	const Image&		Input image
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Description

Loop version of MaximumImage.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE4.1 technology for pixels of types: SINT8, UINT16, SINT32.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

- MaximumImage - Creates an image from the higher pixel values of each corresponding pair.

MedianImages_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Compute median value for each pixel of images from an array.

Syntax

```
void avl::MedianImages_OfArray
(
 const atl::Array<avl::Image>& inImages,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImages	const Array<Image>&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of images in MedianImages_OfArray.
DomainError	Image dimensions are not equal in MedianImages_OfArray.
DomainError	Image formats are not the same in MedianImages_OfArray.
DomainError	Not supported image type in MedianImages_OfArray.
DomainError	Region exceeds an input image in MedianImages_OfArray.

MinimumImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image from the lower pixel values of each corresponding pair.

Syntax

```
void avl::MinimumImage
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

The operation computes the minimum of two images. Each **outImage** pixel is equal to the darker of the corresponding pixels of the input images.

$$\forall_{i,j} \mathbf{OutImage}_{i,j} = \mathrm{Min}(\mathbf{InImage1}_{i,j}, \mathbf{InImage2}_{i,j})$$

In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples

MinimumImage *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE4.1 technology for pixels of types: SINT8, UINT16, SINT32.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in MinimumImage.

MultiplyImages

Header: AVL.h
Namespace: avl
Module: FoundationLite

Multiplies two images pixel by pixel.

Syntax

```
void avl::MultiplyImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	Output image scaling factor
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

The operation computes the product of two images. Each **outImage** pixel is equal to the product of the corresponding pixels of the input images.

$$\forall_{i,j} \mathrm{OutImage}_{i,j} = (\mathrm{InImage1}_{i,j} \cdot \mathrm{InImage2}_{i,j}) \cdot \mathrm{InScale}$$

The result of the operation is multiplied by **inScale** factor, which may be used to avoid clipping when the produced values exceed the range of correct pixel values. However it should be noted that when the value of **inScale** is other than 1.0, the filter uses a slower, not SSE-optimized implementation.

Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL, SINT8(for inScale=1).

This operation is optimized for SSE41 technology for pixels of type: UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, UINT16, SINT16, REAL, SINT8(for inScale=1).

This operation is optimized for NEON technology for pixels of types: UINT8(for inScale!=1), SINT8(for inScale!=1), UINT16(for inScale!=1), SINT16(for inScale!=1), SINT32(for inScale!=1).

This operation supports automatic parallelization for multicore and multiprocessor systems.

- MultiplyImages - Multiplies two images pixel by pixel.

NthImage_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

For each pixel location, get value of n-th (increasing) pixel among input images.

Syntax

```
void avl::NthImage_OfArray
(
 const atl::Array<avl::Image>& inImages,
 const atl::Optional<const atl::Array<avl::Region>&>& inSourceRois,
 int inN,
 bool inReverse,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImages	const Array<Image>&		
→	inSourceRois	const Optional<const Array<Region>&>&	NIL	
→	inN	int		
→	inReverse	bool	False	Reverse the ordering of pixel values to decreasing.
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	ROI exceeds an input image in NthImage_OfArray.
DomainError	Sizes of image array and ROI array differ in NthImage_OfArray.
DomainError	The inN parameter cant be negative.
DomainError	The inN parameter must be smaller than input image array size.

RollingAverageImages_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Averages images appearing in an array pixel by pixel using exponential rolling average.

Syntax

```
void avl::RollingAverageImages_OfArray
(
 const atl::Array<avl::Image>& inImageArray,
 atl::Optional<const avl::Region&> inRoi,
 const float inAlpha,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageArray	const Array<Image>&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inAlpha	const float	0.0 - 1.0	0.5f	
←	outImage	Image&			Output image

Also in AVL Lite

RollingAverageImages_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Averages images appearing in consecutive iterations pixel by pixel using exponential rolling average.

Syntax

```
void avl::RollingAverageImages_OfLoop
(
 ImageCombinators_OfLoopState& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inAlpha,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ImageCombinators_OfLoopState&			Object used to maintain state of the function.
	inImage	const Image&			Input image
	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
	inAlpha	const float	0.0 – 1.0	0.5f	
	outImage	Image&			Output image

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL, SINT8(for inScale=1), UINT16(for inScale=1).

This operation is optimized for SSE41 technology for pixels of types: UINT16(for inScale!=1).

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL, SINT8(for inScale=1).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Also in AVL Lite

SubtractImages

Header: AVL.h
Namespace: avl
Module: FoundationLite

Subtracts two images pixel by pixel.

Syntax

```
void avl::SubtractImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	Output image scaling factor
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage1** and **outImage**, **inImage2** and **outImage**

Read more about In-place Computation.

Description

Operation subtracts two images. Each **outImage** pixel is equal to the difference of corresponding pixels of the input images.

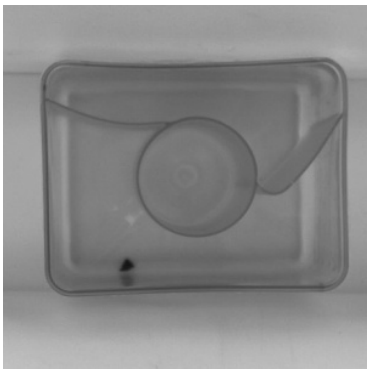
$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \left(\mathrm{InImage1}_{i,j} - \mathrm{InImage2}_{i,j}\right) \cdot \mathrm{InScale}$$

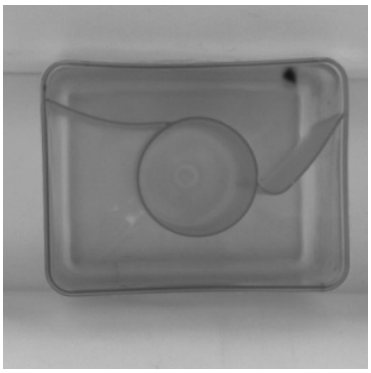
The result of the operation is multiplied by **inScale** factor, which may be used to avoid clipping when the produced values exceed the range of correct pixel values. However it should be noted that when the value of **inScale** is other than 1.0, the filter uses a slower, not SSE-optimized implementation.

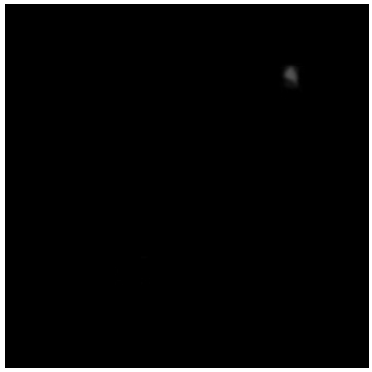
Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples







SubtractImages *performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL, SINT8(for inScale=1), UINT16(for inScale=1).

This operation is optimized for SSE41 technology for pixels of types: UINT16(for inScale!=1).

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL, SINT8(for inScale=1).

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in SubtractImages.
DomainError	Image sizes are not equal in SubtractImages.
DomainError	Region exceeds an input image in SubtractImages.

- AddImages – Adds two images pixel by pixel.
- DifferenceImage – Computes the non-negative distances between corresponding pixel values.

Also in AVL Lite

SubtractImages_Signed

Header: AVL.h
Namespace: avl
Module: FoundationLite

Subtracts two images pixel by pixel. The result is signed.

Syntax

```
void avl::SubtractImages_Signed
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Region&> inRoi,
 float inScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage1	const Image&		First input image
→	inImage2	const Image&		Second input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inScale	float	1.0f	Output image scaling factor
←	outImage	Image&		Output image

Description

Operation subtracts two images. Each **outImage** pixel is equal to the difference of corresponding pixels of the input images. The result is signed.

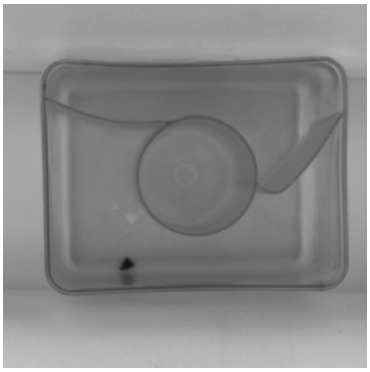
$$\forall_{i,j} \mathrm{OutImage}_{i,j} = \left(\mathrm{InImage1}_{i,j} - \mathrm{InImage2}_{i,j}\right) \cdot \mathrm{InScale}$$

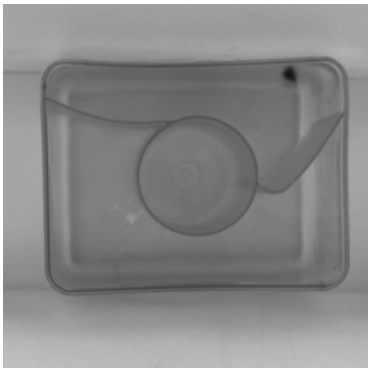
The result of the operation is multiplied by **inScale** factor, which may be used to avoid clipping when the produced values exceed the range of correct pixel values. However it should be noted that when the value of **inScale** is other than 1.0, the filter uses a slower, not SSE-optimized implementation.

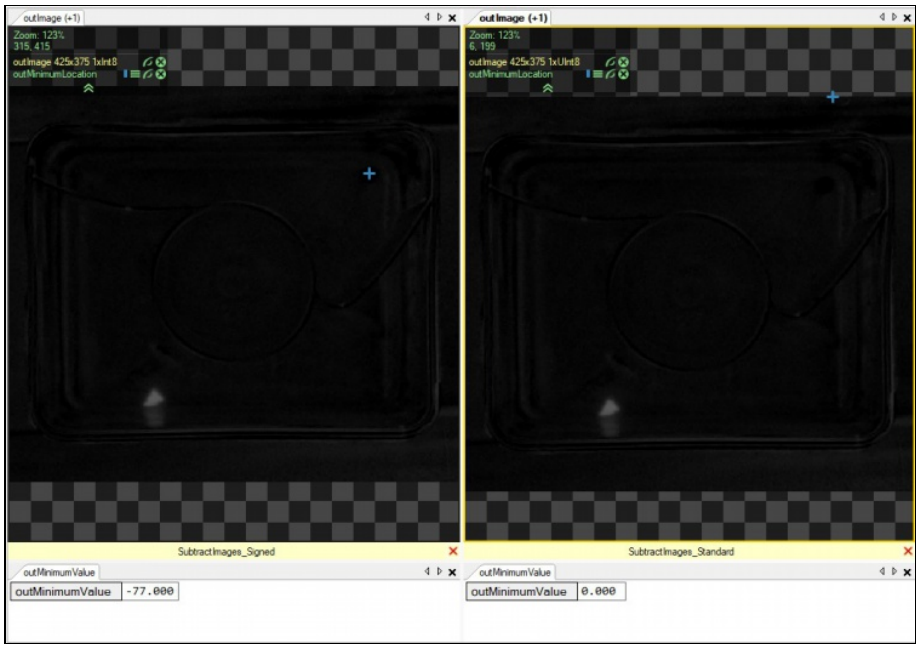
Whenever the resulting value exceeds the range of pixel values, it is clipped to the nearest proper value. In multichannel (color) images each pixel channel is processed separately.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the pixel type of an image one can use ConvertPixelType filter. ConvertToMultichannel and AverageChannels filters allow to alter the number of image channels.

Examples







*Compare **SubtractImages_Signed** and **SubtractImages** performed on the sample images.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL, SINT8(for inScale=1), UINT16(for inScale=1).

This operation is optimized for SSE41 technology for pixels of types: UINT16(for inScale!=1).

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL, SINT8(for inScale=1).

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in SubtractImages_Signed.
DomainError	Image sizes are not equal in SubtractImages_Signed.
DomainError	Region exceeds an input image in SubtractImages_Signed.

See Also

- AddImages – Adds two images pixel by pixel.
- DifferenceImage – Computes the non-negative distances between corresponding pixel values.

20. Shape Adjustment

Table of content:

- AdjustPathArraysToEdges
- AdjustPathArrayToEdges

AdjustPathArraysToEdges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Translates, rotates and scales multiple contour sets (PathArray), each separately, to the edges of the input image with subpixel precision.

Applications: Fine-tune results of edge-based template matching.

Syntax

```
void avl::AdjustPathArraysToEdges
(
 const avl::Image& inImage,
 const atl::Array<atl::Array<avl::Path>>& inPaths,
 atl::Optional<float> inPointSpacing,
 atl::Optional<const atl::Array<avl::CoordinateSystem2D>&> inAlignments,
 float inAttractionRadius,
 avl::AdjustmentMetric::Type inAdjustmentMetric,
 bool inAdjustTranslation,
 bool inAdjustRotation,
 bool inAdjustScale,
 int inIterationCount,
 float inBaseGradient,
 atl::Array<atl::Array<avl::Path>>& outAdjustedPaths,
 atl::Array<avl::CoordinateSystem2D>& outAlignments,
 atl::Array<atl::Array<avl::Segment2D>>& diagAttractionVectors
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image.
→	inPaths	const Array<Array<Path>>&			Paths to be adjusted. For sparse, synthetic paths the inPointSpacing needs to be specified.
→	inPointSpacing	Optional<float>	1.0 – ∞	NIL	If set, sampling points of the input path will be equidistant with specified spacing. Useful for increasing density of synthetic, sparse paths.
→	inAlignments	Optional<const Array<CoordinateSystem2D>&>		NIL	Alignments to be corrected, usually connect to outObjects.Alignment[] of LocateObjects:Multiple filter.
→	inAttractionRadius	float	0.1 – ∞	2.0f	Expected initial distance between inPaths and edges of the input image.
→	inAdjustmentMetric	AdjustmentMetric::Type		SegmentDistance	Metric used for path attraction. The SegmentDistance minimizes distances along path normal vectors, and thus adjustment is more accurate. PointDistance_* minimize euclidean distance, adjustment tends to be more stable.
→	inAdjustTranslation	bool		True	Compute the translation part of adjustment transform. Must be true when using AttractPathTangents estimation method.
→	inAdjustRotation	bool		True	Compute the rotation part of adjustment transform.
→	inAdjustScale	bool		False	Compute the scale part of adjustment transform.
→	inIterationCount	int	0 – 100	6	Number of iterations of internal adjustment algorithm.
→	inBaseGradient	float	0.1 – ∞	1.0f	Threshold for suppression of weak input image gradients. Increase for very noisy images.
←	outAdjustedPaths	Array<Array<Path>>&			Adjusted output paths.
←	outAlignments	Array<CoordinateSystem2D>&			Corrected alignments – inAlignments input modified with estimated adjustment parameters.
🔍	diagAttractionVectors	Array<Array<Segment2D>>&			Attraction vectors from first iteration.

Hints

- This filter is a multiple object version of AdjustPathArrayToEdges, however it achieves much higher performance than AdjustPathArrayToEdges executed in a loop.
- Please refer to AdjustPathArrayToEdges documentation for more information.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inPaths and inAlignments have different size
DomainError	To use SegmentDistance adjustment metric, inAdjustTranslation must be enabled.

See Also

- AdjustPathArrayToEdges – Translates, rotates and scales the given contour set to the edges of the input image with subpixel precision.
- EnhanceSingleObjectMatch – Improves accuracy of single object matching by adding a subpixel-precise adjustment.
- EnhanceMultipleObjectMatches – Improves accuracy of multiple object matching by adding a subpixel-precise adjustment.

AdjustPathArrayToEdges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Translates, rotates and scales the given contour set to the edges of the input image with subpixel precision.

Applications: Fine-tune results of edge-based template matching.

Syntax

```
void avl::AdjustPathArrayToEdges
(
 const avl::Image& inImage,
 const atl::Array< avl::Path >& inPaths,
 atl::Optional<float> inPointSpacing,
 atl::Optional<const avl::CoordinateSystem2D&> inAlignment,
 float inAttractionRadius,
 avl::AdjustmentMetric::Type inAdjustmentMetric,
 bool inAdjustTranslation,
 bool inAdjustRotation,
 bool inAdjustScale,
 int inIterationCount,
 float inBaseGradient,
 atl::Array< avl::Path >& outAdjustedPaths,
 avl::CoordinateSystem2D& outAlignment,
 atl::Array<avl::Segment2D>& diagAttractionVectors
)
```

Parameters

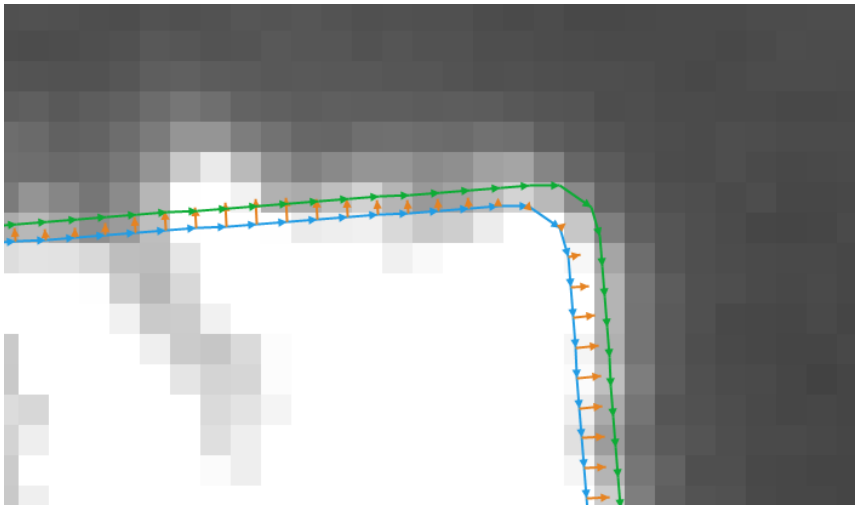
	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image.
➡	inPaths	const Array< Path >&			Paths to be adjusted. For sparse, synthetic paths the inPointSpacing needs to be specified.
➡	inPointSpacing	Optional<float>	1.0 – ∞	NIL	If set, sampling points of the input path will be equidistant with specified spacing. Useful for increasing density of synthetic, sparse paths.
➡	inAlignment	Optional<const CoordinateSystem2D&>		NIL	Alignment to be corrected, usually connects to outObject.Alignment of LocateObjects filter.
➡	inAttractionRadius	float	0.1 – ∞	2.0f	Expected initial distance between inPaths and edges of the input image.
➡	inAdjustmentMetric	AdjustmentMetric::Type		SegmentDistance	Metric used for path attraction. The SegmentDistance minimizes distances along path normal vectors, and thus adjustment is more accurate. PointDistance_* minimize euclidean distance, adjustment tends to be more stable.
➡	inAdjustTranslation	bool		True	Compute the translation part of adjustment transform. Must be true when using AttractPathTangents estimation method.
➡	inAdjustRotation	bool		True	Compute the rotation part of adjustment transform.
➡	inAdjustScale	bool		False	Compute the scale part of adjustment transform.
➡	inIterationCount	int	0 – 100	6	Number of iterations of internal adjustment algorithm.
➡	inBaseGradient	float	0.1 – ∞	1.0f	Threshold for suppression of weak input image gradients. Increase for very noisy images.
⬅	outAdjustedPaths	Array< Path >&			Adjusted output paths.
⬅	outAlignment	CoordinateSystem2D&			Corrected alignment – the inAlignment input modified with estimated adjustment parameters.
🔍	diagAttractionVectors	Array<Segment2D>&			Attraction vectors from first iteration.

Hints

- In order to use the filter to fine-tune the results of template matching, connect the **outObjectEdges** output of the template matching filter to the **inPaths** input, **outObject.Alignment** to **inAlignment** and the same input image to the **inImage** input.
- When using template matching with AdjustPathArrayToEdges filter, you may try to speed up template matching by increasing its **inMinPyramidLevel** parameter. The potential loss of template matching precision should be mitigated by the AdjustPathArrayToEdges filter.
- The **inAttractionRadius** should be set to the average initial distance between inPaths and edges of the input image. Although the filter tolerance to this parameter is high, setting it too low may result in adjustment failure, setting it too high will result in reduced accuracy. The parameter directly influences attraction vectors, which may be observed via diagnostic output **diagAttractionVectors**.
- **SegmentDistance** is the default value of **inAdjustmentMetric** parameter and usually it is the best choice. However, in some special cases one should consider other options:
  - **inImage** contains glares – the **PointDistance_Median** method may perform better as the median error metric is more robust than least squares.
  - **inPaths** is a degenerate path array, such as a 1D straight line – the **SegmentDistance** could fail, the **PointDistance_*** methods may work.

  Please note that you need to increase **inIterationCount** to **10** when using **PointDistance_*** adjustment metrices, as the default value of **6** is fine-tuned to the **SegmentDistance** metric.
- Increasing **inIterationCount** may result in more accurate results, however gains are diminishing quickly. The only downside of increasing **inIterationCount** in higher computation time.
- Sparse paths – with a low amount of points – need to be densened to obtain acceptable accuracy and stability of the filter. Set the **inPointSpacing** parameter to a desired distance between consecutive path points.
- For paths with large amount of points, the filter execution may be considerably accelerated without perceivable influence on the accuracy. Set the **inPointSpacing** parameter to a value higher than average spacing of input paths.
- Noise on the input image may introduce false adjustment vectors, reducing accuracy. To mitigate the influence of noise, the **inBaseGradient** parameter may be used, which governs suppression of weak input image gradients. In order to tune the parameter, observe the **diagAttractionVectors** output. Note that its better to have some noise in attraction vectors directions than to considerably reduce their strength.
- When dealing with multiple objects on a single image, use the AdjustPathArraysToEdges for improved performance.

Examples



Improving results of template matching. Blue – input paths, orange – attraction vectors, green – corrected paths.

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

AdjustPointArrays

Header: AVL.h
Namespace: avl
Module: FoundationPro

Aligns a point array to match best the input point array.

Syntax

```
void avl::AdjustPointArrays
(
 const atl::Array<avl::Point2D>& inPoints,
 const atl::Array<avl::Point2D>& inReferencePoints,
 const bool inAllowRotation,
 const bool inAllowScale,
 const int inMaxIterationCount,
 const float inMatchFraction,
 const int inInitialTransformCount,
 atl::Conditional<atl::Array<avl::Point2D> >& outAlignedPoints,
 atl::Conditional<avl::CoordinateSystem2D>& outAlignment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Points to be aligned
→	inReferencePoints	const Array<Point2D>&			Points to align to
→	inAllowRotation	const bool		True	Flag indicating whether rotation is allowed as a part of output alignment
→	inAllowScale	const bool		False	Flag indicating whether scale is allowed as a part of output alignment
→	inMaxIterationCount	const int	1 – ∞	10	Maximal number of iteration for the algorithm
→	inMatchFraction	const float	0.0 – 1.0	0.75f	Defines fraction of input points that is being fitted in every iteration
→	inInitialTransformCount	const int	1 – ∞	10	Number of initial transforms to be tried out by the algorithm
←	outAlignedPoints	Conditional<Array<Point2D> >&			The aligned input points
←	outAlignment	Conditional<CoordinateSystem2D>&			The transform that aligns best the input points

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in AdjustPointArrays.

DetectPointSegments

Header: AVL.h
Namespace: avl
Module: FoundationPro

Detect points that lie along multiple segments.

Syntax

```
void avl::DetectPointSegments
(
 const atl::Array<avl::Point2D>& inPoints,
 const float inMaxDistance,
 const int inMaxRank,
 atl::Optional<float> inMaxRelativeDistance,
 const float inMaxTurnAngle,
 const int inMinPointCount,
 atl::Array<avl::Segment2D>& outPointSegments,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Points to connect
→	inMaxDistance	const float	0.0 – ∞	10.0f	Maximum distance between connected points
→	inMaxRank	const int	1 – ∞	4	Maximum number of neighbour candidates considered when joining points
→	inMaxRelativeDistance	Optional<float>	1.0 – ∞	2.0f	Maximum distance in relation to the shortest distance for a point
→	inMaxTurnAngle	const float	0.0 – 90.0	5.0f	Maximum angle between consecutive path segments
→	inMinPointCount	const int	2 – ∞	3	Minimum number of points in one path
←	outPointSegments	Array<Segment2D>&			Segments connecting first and last point of each path
←	outPaths	Array<Path>&			Paths of connected points

Description

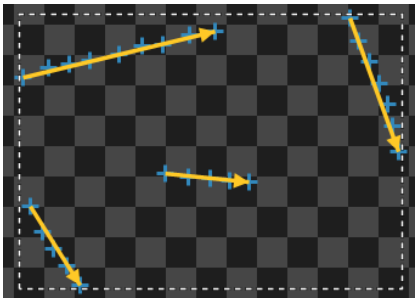
Use this filter to detect multiple segments or paths at the same time.

Set **inMaxDistance** to smaller value to avoid connecting distant points.
Set **inMaxRank** to larger value to allow detecting paths that lie close to each other.
Set **inMaxTurnAngle** to larger value when points do not lie precisely on a segment.
Set **inMinPointCount** to filter out too short paths (useful when some of the input points are noise).

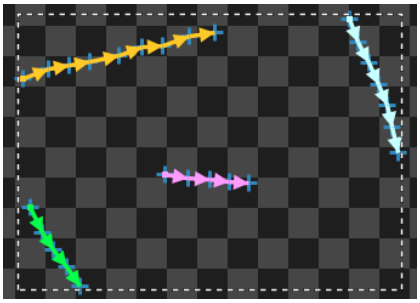
Filter returns array of paths as well as segments connecting first and last point of each path.

Examples

*Results for input parameters: **inMaxDistance** = 30, **inMaxRank** = 4, **inMaxTurnAngle** = 20, **inMinPointCount** = 4.*



*The resulting **outPointSegments** drawn with the input points.*



*The resulting **outPaths** drawn with the input points.*

See Also

- FitSegmentToPoints – Approximates points with a segment using selected outliers suppression method.

DetectPointSegments_Ex

Header: AVL.h
Namespace: avl
Module: FoundationPro

Detect points that lie along multiple segments.

Syntax

```
void avl::DetectPointSegments_Ex
(
 const atl::Array<avl::Point2D>& inPoints,
 const float inMaxDistance,
 const int inMaxRank,
 atl::Optional<float> inMaxRelativeDistance,
 const float inMaxTurnAngle,
 const int inMinPointCount,
 atl::Array<avl::Segment2D>& outPointSegments,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Points to connect
→	inMaxDistance	const float	0.0 – ∞	10.0f	Maximum distance between connected points
→	inMaxRank	const int	1 – ∞	4	Maximum number of neighbour candidates considered when joining points
→	inMaxRelativeDistance	Optional<float>	1.0 – ∞	2.0f	Maximum distance in relation to the shortest distance for a point
→	inMaxTurnAngle	const float	0.0 – 90.0	5.0f	Maximum angle between consecutive path segments
→	inMinPointCount	const int	2 – ∞	3	Minimum number of points in one path
←	outPointSegments	Array<Segment2D>&			Segments connecting first and last point of each path
←	outPaths	Array<Path>&			Paths of connected points

FitArcToPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates path by an arc using the selected outliers suppression method and considering path's start and end.

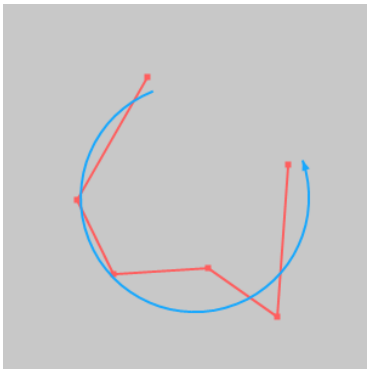
Syntax

```
void avl::FitArcToPath
(
 const avl::Path& inPath,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Arc2D>& outArc
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inFittingMethod	CircleFittingMethod::Type		
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	
←	outArc	Conditional<Arc2D>&		Fitted arc or nothing if the computations failed to converge

Examples



*The resulting **outArc** drawn with the input path, **inFittingMethod** = AlgebraicKasa and **inOutlierSuppression** = Auto.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Outlier suppression is supported only in algebraic fitting methods.

FitArcToPoints

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with an arc using the selected outliers suppression method.

Syntax

```
void avl::FitArcToPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Arc2D>& outArc,
 atl::Optional<atl::Array<avl::Point2D>&> outInliers = atl::NIL
)
```

Parameters

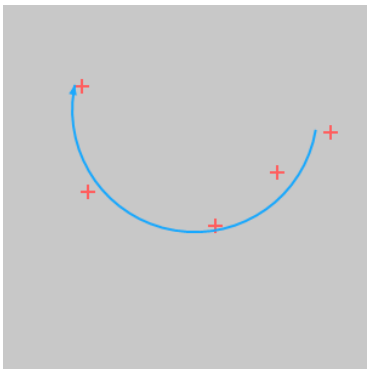
	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRange	Optional<const Range&>	NIL	Determines which array points take part in fitting process
→	inFittingMethod	CircleFittingMethod::Type		
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	
←	outArc	Conditional<Arc2D>&		Fitted arc or nothing if the computations failed to converge
←	outInliers	Optional<Array<Point2D>&>	NIL	Points matching the fitting arc

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Examples



*The resulting **outArc** drawn with the input points, **inFittingMethod** = AlgebraicKasa and **inOutlierSuppression** = Auto.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Outlier suppression is supported only in algebraic fitting methods.
DomainError	Range exceeds the input point array in FitArcToPoints.

FitCircleToPoints

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a circle using selected outliers suppression method.

Syntax

```
void avl::FitCircleToPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Circle2D>& outCircle,
 atl::Optional<atl::Array<avl::Point2D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRange	Optional<const Range&>	NIL	Determines which array points take part in fitting process
→	inFittingMethod	CircleFittingMethod::Type		
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	
←	outCircle	Conditional<Circle2D>&		Fitted circle or nothing if method failed to converge
←	outInliers	Optional<Array<Point2D>&>	NIL	Points matching the computed circle

Optional Outputs

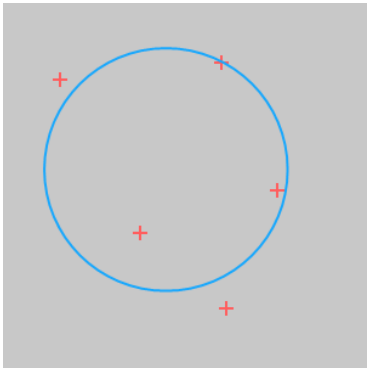
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Description

The operation computes a circle which approximates the input points best. Several methods are available, **AlgebraicKasa** being the fastest one. It is also the most inaccurate when the input points are sampled along small arc only.

Examples



*The resulting **outCircle** drawn with the input points, **inFittingMethod** = AlgebraicKasa and **inOutlierSuppression** = Auto.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Outlier suppression is supported only in algebraic fitting methods.
DomainError	Range exceeds the input point array in FitCircleToPoints.

See Also

- FitArcToPoints – Approximates points with an arc using the selected outliers suppression method.
- FitLineToPoints – Approximates points with a line using the Least Squares method.

FitLineToPoints

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a line using the Least Squares method.

Syntax

```
void avl::FitLineToPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::Line2D& outLine,
 atl::Optional<float&> outError = atl::NIL
)
```

Parameters

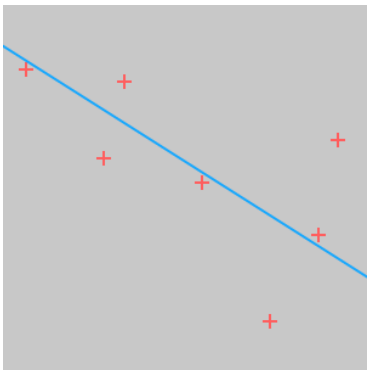
	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRange	Optional<const Range&>	NIL	Determines which array points take part in fitting process
←	outLine	Line2D&		
←	outError	Optional<float&>	NIL	Sum of the point distances from the output line

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outError**.

Read more about Optional Outputs.

Examples



*The resulting **outLine** drawn with the input points.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitLineToPoints.
DomainError	Range exceeds the input point array in FitLineToPoints.

FitLineToPoints_LTE

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a line using Least Trimmed Error algorithm.

Applications: Brute-force finding of a line that best matches a subset of the input points. Very efficient against outliers, but possibly slow for bigger subsets.

Syntax

```
void avl::FitLineToPoints_LTE
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 int inSeedSubsetSize,
 atl::Optional<int> inEvalSubsetSize,
 avl::Line2D& outLine,
 atl::Optional<atl::Array<avl::Point2D>&> outLTInliers = atl::NIL,
 atl::Optional<float&> outLTError = atl::NIL,
 int& diagIterationCount = atl::Dummy<int>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inSeedSubsetSize	int	2 – 10	3	Number of points in one combination for getting a sample line
→	inEvalSubsetSize	Optional<int>	3 – ∞	NIL	Number of closest points used for evaluation of a sample line, or Auto if seed points are to be used
←	outLine	Line2D&			Fitted line
←	outLTInliers	Optional<Array<Point2D>&>		NIL	Inlying points of the best LTE line
←	outLTError	Optional<float&>		NIL	The Least Trimmed Error
🔍	diagIterationCount	int&			Number of combinations considered

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLTInliers**, **outLTError**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitLineToPoints_LTE.
DomainError	Range exceeds the input point array in FitLineToPoints_LTE.

FitLineToPoints_M

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a line using selected M-estimator for outlier suppression.

Applications: Finding a locally optimal line. Good enough when the number of outliers is small.

Syntax

```
void avl::FitLineToPoints_M
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Line2D&> inInitialLine,
 avl::Line2D& outLine,
 atl::Optional<atl::Array<avl::Point2D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialLine	Optional<const Line2D&>		NIL	Initial approximation (if available)
←	outLine	Line2D&			
←	outInliers	Optional<Array<Point2D>&>		NIL	Points matching the computed line

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitLineToPoints_M.
DomainError	Range exceeds the input point array in FitLineToPoints_M.

FitLineToPoints_RANSAC

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a line using a RANSAC algorithm.

Applications: Finds a well matching line, but for handling outliers requires a distance threshold that may be difficult to set.

Syntax

```
void avl::FitLineToPoints_RANSAC
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 atl::Optional<int> inMaxOutlierCount,
 float inMaxInlierDistance,
 atl::Optional<int> inIterationCount,
 atl::Conditional<avl::Line2D>& outLine
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inMaxOutlierCount	Optional<int>	0 – ∞	0	Determines how many outlier points can be present to end the search
→	inMaxInlierDistance	float	0.0 – ∞	3.0f	Distance from the output line for a point to be considered an inlier
→	inIterationCount	Optional<int>	1 – ∞	42	Number of iterations; Auto means that all point pairs will be used
←	outLine	Conditional<Line2D>&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitLineToPoints_RANSAC.
DomainError	Range exceeds the input point array in FitLineToPoints_RANSAC.

FitLineToPoints_TheilSen

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a line using TheilSen algorithm, optionally with Siegel's improvement.

Applications: Finds a well matching line, ignoring up to 29.3% (TheilSen) or 50.0% (Siegel) outliers. Outliers do have some influence on accuracy.

Syntax

```
void avl::FitLineToPoints_TheilSen
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::TheilSenVariant::Type inVariant,
 atl::Optional<int> inSampleLimit,
 atl::Optional<float> inOutlierRatio,
 avl::Line2D& outLine,
 atl::Array<float>& diagOrientations
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inVariant	TheilSenVariant::Type			Switches between Theil-Sen and Siegel methods
→	inSampleLimit	Optional<int>	5 – ∞	NIL	How many pairs of points are used to estimate orientation
→	inOutlierRatio	Optional<float>	0.0 – 0.99	NIL	
←	outLine	Line2D&			Fitted line
🔍	diagOrientations	Array<float>&			Sample orientations used to determine the output line orientation

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitLineToPoints_TheilSen.
DomainError	Range exceeds the input point array in FitLineToPoints_TheilSen.

FitSegmentToPoints

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a segment using selected outliers suppression method.

Applications: Finding a locally optimal segment. Good enough when the number of outliers is small.

Syntax

```
void avl::FitSegmentToPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 avl::Segment2D& outSegment,
 atl::Optional<atl::Array<avl::Point2D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRange	Optional<const Range&>	NIL	Determines which array points take part in fitting process
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	
←	outSegment	Segment2D&		
←	outInliers	Optional<Array<Point2D>&>	NIL	

Optional Outputs

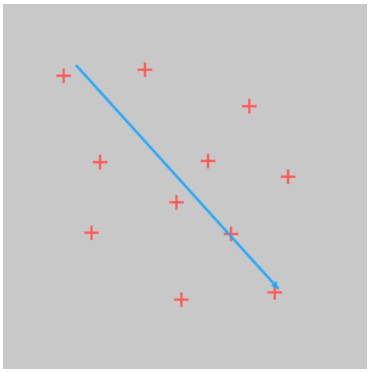
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Description

The orientation of the resulting **outSegment** is always between 0 and 180 degrees.

Examples



*The resulting **outSegment** drawn with the input points, **inOutlierSuppression** = Auto.*

FitSegmentToPoints_LTE

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a segment using Least Trimmed Error algorithm.

Applications: Brute-force finding of a segment that best matches a subset of the input points. Very efficient against outliers, but possibly slow for bigger subsets.

Syntax

```
void avl::FitSegmentToPoints_LTE
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 int inSeedSubsetSize,
 atl::Optional<int> inEvalSubsetSize,
 avl::Segment2D& outSegment,
 atl::Optional<atl::Array<avl::Point2D>&> outLTInliers = atl::NIL,
 atl::Optional<float&> outLTError = atl::NIL,
 int& diagIterationCount = atl::Dummy<int>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inSeedSubsetSize	int	2 – 10	3	Number of points in one combination for getting a sample segment
→	inEvalSubsetSize	Optional<int>	3 – ∞	NIL	Number of closest points used for evaluation of a sample segment, or Auto if seed points are to be used
←	outSegment	Segment2D&			Fitted segment
←	outLTInliers	Optional<Array<Point2D>&>		NIL	Inlying points of the best LTE segment
←	outLTError	Optional<float&>		NIL	The Least Trimmed Error
🔍	diagIterationCount	int&			Number of combinations considered

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLTInliers**, **outLTError**.

FitSegmentToPoints_TheilSen

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates points with a segment using TheilSen algorithm, optionally with Siegel's improvement.

Applications: Finds a well matching segment, ignoring up to 29.3% (TheilSen) or 50.0% (Siegel) outliers. Outliers do have some influence on accuracy.

Syntax

```
void avl::FitSegmentToPoints_TheilSen
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Range&> inRange,
 avl::TheilSenVariant::Type inVariant,
 atl::Optional<int> inSampleLimit,
 atl::Optional<float> inOutlierRatio,
 avl::Segment2D& outSegment,
 atl::Array<float>& diagOrientations
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inRange	Optional<const Range&>		NIL	Determines which array points take part in fitting process
→	inVariant	TheilSenVariant::Type			Switches between Theil-Sen and Siegel methods
→	inSampleLimit	Optional<int>	5 – ∞	NIL	How many pairs of points are used to estimate orientation
→	inOutlierRatio	Optional<float>	0.0 – 0.99	NIL	
←	outSegment	Segment2D&			Fitted segment
🔍	diagOrientations	Array<float>&			Sample orientations used to determine the output line orientation

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in FitSegmentToPoints_TheilSen.
DomainError	Range exceeds the input point array in FitSegmentToPoints_TheilSen.

FitSegmentToRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Approximates a region with a segment using selected outliers suppression method.

Applications: Finding a locally optimal segment. Good enough when the number of outliers is small.

Syntax

```
void avl::FitSegmentToRegion
(
 const avl::Region& inRegion,
 const avl::RegionSegmentFittingMethod::Type inMethod,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inMethod	const RegionSegmentFittingMethod::Type		
←	outSegment	Segment2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate convex hull on input in FitSegmentToRegion.
DomainError	Empty region on input in FitSegmentToRegion.

LocateMultiplePointPatterns

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds occurrences of a pattern in a 2D cloud of (feature) points.

Applications: Can be used to find entire objects after finding their characteristic points with tools such as Template Matching or DL_LocatePoints.

Syntax

```
void avl::LocateMultiplePointPatterns
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const atl::Array<int>&> inPointLabels,
 const atl::Array<avl::Point2D>& inPattern,
 atl::Optional<const atl::Array<int>&> inPatternLabels,
 atl::Optional<const avl::Rectangle2D&> inReferenceFrame,
 const bool inAllowRotation,
 const float inMinAngle,
 const float inMaxAngle,
 const bool inAllowScale,
 const float inMinScale,
 const float inMaxScale,
 const float inTilingFactor,
 const float inMinInitialScore,
 const float inMaxDeviation,
 const float inMinScore,
 const float inMinDistance,
 const bool inDisjointObjectsOnly,
 atl::Array<avl::Rectangle2D>& outObjects,
 atl::Array<atl::Array<avl::Point2D> >& outAlignedPatterns,
 atl::Array<avl::CoordinateSystem2D>& outAlignments,
 atl::Array<atl::Array<avl::Segment2D> >& outPatternSkeletons
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inPointLabels	Optional<const Array<int>&>		NIL	Categories that the input points belong to
→	inPattern	const Array<Point2D>&			Point pattern to be found
→	inPatternLabels	Optional<const Array<int>&>		NIL	Categories that the pattern points belong to
→	inReferenceFrame	Optional<const Rectangle2D&>		NIL	Exact position of the model object associated with the pattern in the image
→	inAllowRotation	const bool		True	Flag indicating whether rotation is allowed as a part of output alignment
→	inMinAngle	const float		-180.0f	Start of range of possible rotations
→	inMaxAngle	const float		180.0f	End of range of possible rotations
→	inAllowScale	const bool		False	Flag indicating whether scale is allowed as a part of output alignment
→	inMinScale	const float	0.0 – ∞	0.8f	Start of range of possible scales
→	inMaxScale	const float	0.0 – ∞	1.25f	End of range of possible scales
→	inTilingFactor	const float	0.000001 – 1.0	0.2f	Defines relative size of the square tile on the plane during initial detection
→	inMinInitialScore	const float	0.0 – 1.0	0.75f	The minimum proportion of points correctly matched during initial detection
→	inMaxDeviation	const float	0.0 – ∞	5.0f	Maximal distance between two points considered matched
→	inMinScore	const float	0.0 – 1.0	0.75f	The minimum proportion of points correctly matched
→	inMinDistance	const float	0.0 – ∞	10.0f	Minimal distance between centers of two found occurrences
→	inDisjointObjectsOnly	const bool		False	Flag indicating whether found occurrences can have common points
←	outObjects	Array<Rectangle2D>&			Bounding rectangles of the found pattern occurrences
←	outAlignedPatterns	Array<Array<Point2D> >&			The aligned input pattern points
←	outAlignments	Array<CoordinateSystem2D>&			The transforms that align the input pattern to the input points
←	outPatternSkeletons	Array<Array<Segment2D> >&			The skeletons of the aligned input pattern points

Description

The filter finds locations of a pattern of points in the set of input points. The possible rotations and scales of the found occurrences can be fully controlled using proper values of **inAllowRotation**, **inMinAngle**, **inMaxAngle**, **inAllowScale**, **inMinScale** and **inMaxScale** parameters.

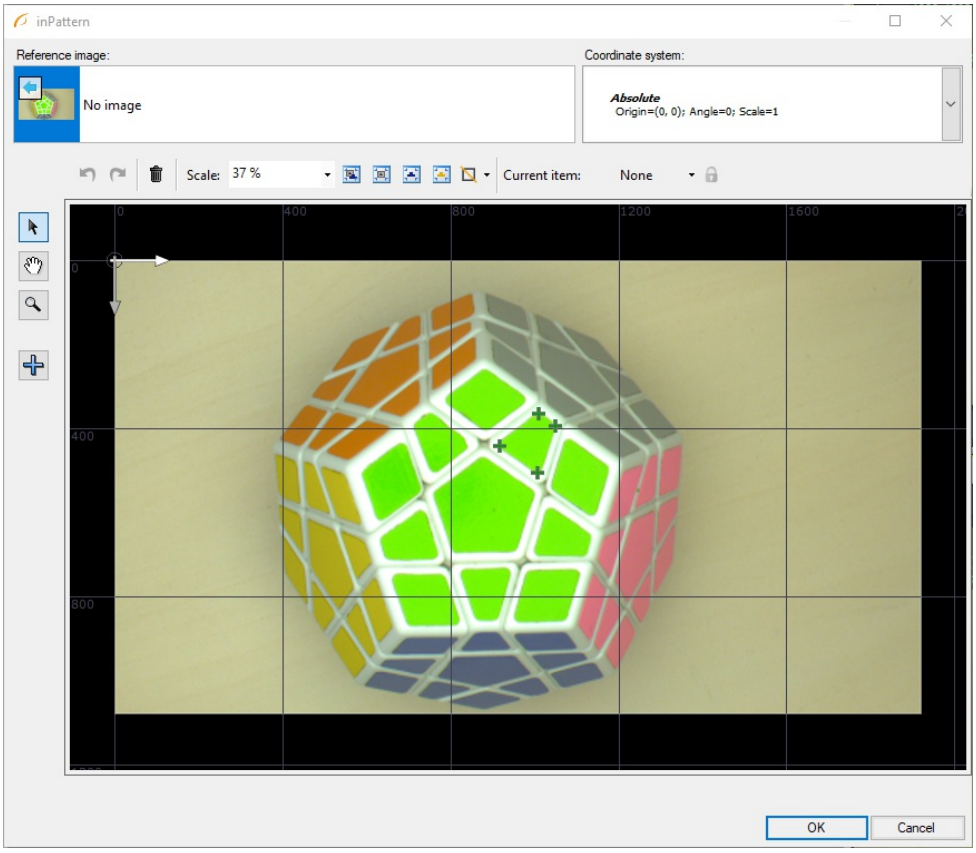
The location routine consists of three phases. Only the **inTilingFactor** and **inMinInitialScore** parameters have an effect on the initial phase. Internally, the whole plane is then divided into square tiles which size depends on **inTilingFactor** and the average distance between two points from **inPoints**. A transformation becomes a candidate to be a valid pattern occurrence if at least **inMinInitialScore** fraction of pattern points reside in the right tiles. The candidate transformation proceeds to the second phase, where it is refined to be possibly best fitted to the data points. The result transformation is considered to be a valid output alignment if at least **inMinScore** fraction of aligned pattern points are at most **inMaxDeviation** away from their closest data points.

The end phase's purpose is to select the output alignments according to the **inMinDistance** and **inDisjointObjectsOnly** parameters values. The ultimate output is chosen so no two aligned pattern centers are closer than **inMinDistance** from themselves and, if **inDisjointObjectsOnly** parameter is set, no two aligned patterns cover the same data point.

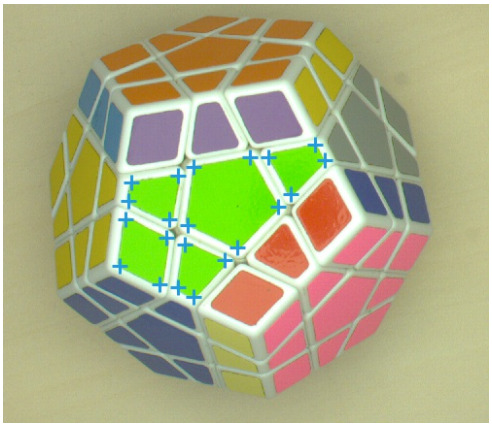
The most difficult part to achieve reliable results seems to be the proper setting of the **inTilingFactor** parameter. Because of its existence, the algorithm will work especially well when the pattern consists of not too many points and distances between them are more or less equal i.e. the ratio of the greatest distance between pattern points and the smallest distance between pattern points is small. If this is not the case and the default value for **inTilingFactor** does not work well, one should try to adjust the value keeping in mind that the greater values should be used when the pattern visible in the **inPoints** is distorted and the smaller values will work best when only small distortion is present. In case of further problems with choosing the right **inTilingFactor** value, one can also try lowering **inMinInitialScore** value.

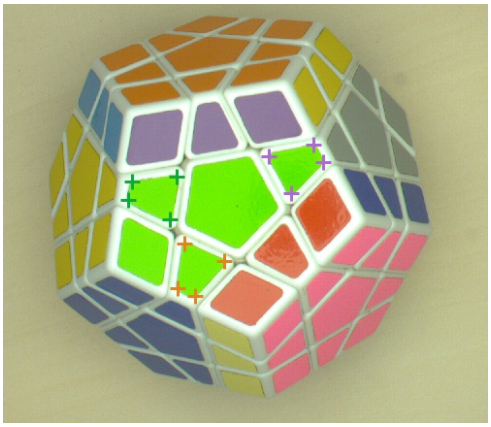
The filter performance depends heavily on the number of the pattern points. Because of that fact, it is highly advisable for the pattern to be as small as possible. The performance can be poor even for patterns with more than 15 points. Note that the shape of the pattern also matters. The execution time for symmetrical patterns is generally bigger than for asymmetrical ones.

Examples



inPattern *input with selected point pattern to be found*





LocateMultiplePointPatterns *performed on points acquired by* ***DL_LocatePoints****.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input pattern and input pattern labels sizes are not equal in LocateMultiplePointPatterns.
DomainError	Input pattern is empty in LocateMultiplePointPatterns.
DomainError	Input points and input point labels sizes are not equal in LocateMultiplePointPatterns.
DomainError	Point labels should be both present or both absent in LocateMultiplePointPatterns.

←	outAlignment	Conditional<CoordinateSystem2D>&			The transform that align the input pattern to the input points
←	outPatternSkeleton	Conditional<Array<Segment2D> >&			The skeleton of the aligned input pattern points

Description

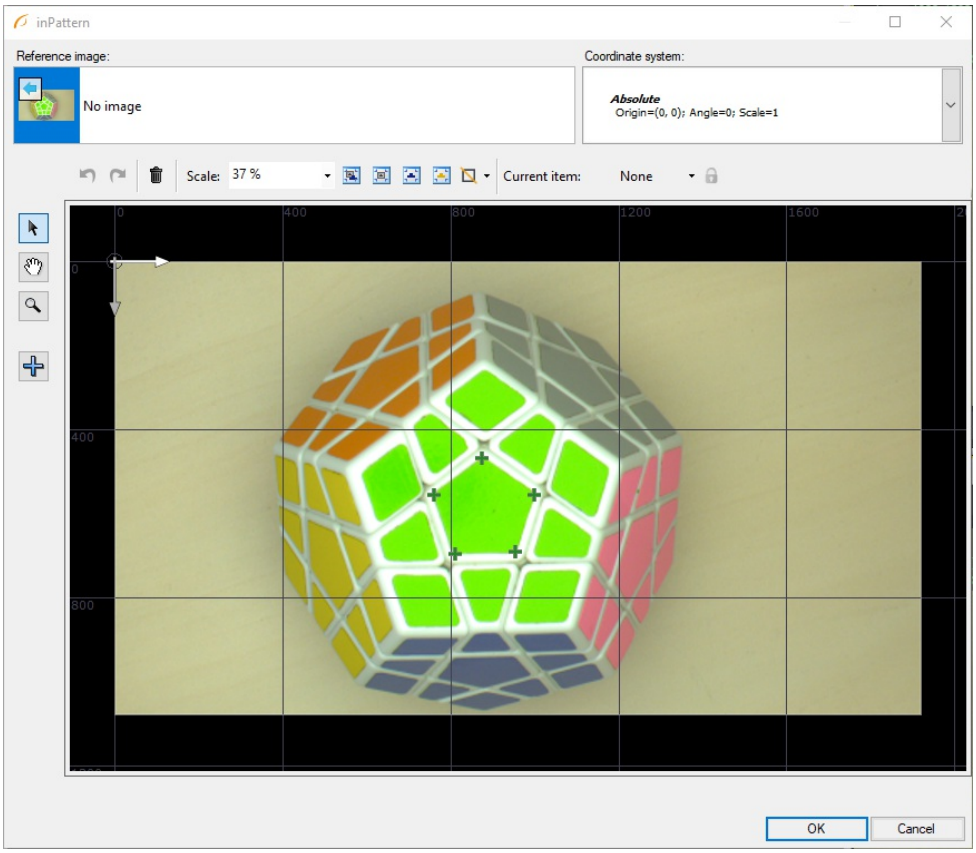
The filter finds location of a pattern of points in the set of input points. The possible rotation and scale of the found occurrence can be fully controlled using proper values of **inAllowRotation**, **inMinAngle**, **inMaxAngle**, **inAllowScale**, **inMinScale** and **inMaxScale** parameters.

The location routine consists of two phases. Only the **inTilingFactor** and **inMinInitialScore** parameters have an effect on the initial phase. Internally, the whole plane is then divided into square tiles which size depends on **inTilingFactor** and the average distance between two points from **inPoints**. A transformation becomes a candidate to be a valid pattern occurrence if at least **inMinInitialScore** fraction of pattern points reside in the right tiles. The candidate transformation proceeds to the second phase, where it is refined to be possibly best fitted to the data points. The result transformation is considered to be a valid output alignment if at least **inMinScore** fraction of aligned pattern points are at most **inMaxDeviation** away from their closest data points.

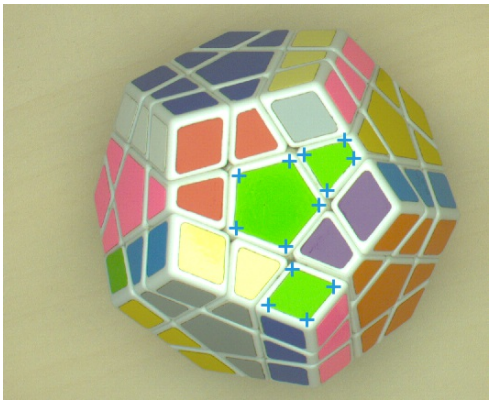
The most difficult part to achieve reliable results seems to be the proper setting of the **inTilingFactor** parameter. Because of its existence, the algorithm will work especially well when the pattern consists of not too many points and distances between them are more or less equal i.e. the ratio of the greatest distance between pattern points and the smallest distance between pattern points is small. If this is not the case and the default value for **inTilingFactor** does not work well, one should try to adjust the value keeping in mind that the greater values should be used when the pattern visible in the **inPoints** is distorted and the smaller values will work best when only small distortion is present. In case of further problems with choosing the right **inTilingFactor** value, one can also try lowering **inMinInitialScore** value.

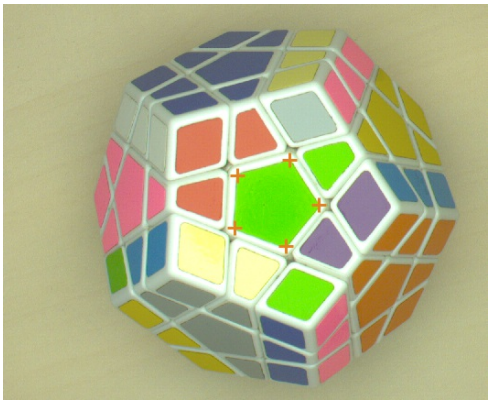
The filter performance depends heavily on the number of the pattern points. Because of that fact, it is highly advisable for the pattern to be as small as possible. The performance can be poor even for patterns with more than 15 points. Note that the shape of the pattern also matters. The execution time for symmetrical patterns is generally bigger than for asymmetrical ones.

Examples



***inPattern** input with selected point pattern to be found*





LocateSinglePointPattern** performed on points acquired by **DL_LocatePoints

Errors

List of possible exceptions:

Error type	Description
DomainError	Input pattern and input pattern labels sizes are not equal in LocateSinglePointPattern.
DomainError	Input pattern is empty in LocateSinglePointPattern.
DomainError	Input points and input point labels sizes are not equal in LocateSinglePointPattern.
DomainError	Point labels should be both present or both absent in LocateSinglePointPattern.

AdjustPointGrids3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Aligns (rotation + translation) a point grid to match best the reference point grid.

Syntax

```
void avl::AdjustPointGrids3D
(
 const avl::Point3DGrid& inPoints,
 const avl::Point3DGrid& inReferencePoints,
 const int inMaxIterationCount,
 const float inMatchFraction,
 const float inDiscardFurthestFraction,
 avl::Point3DGrid& outAlignedPoints,
 avl::Matrix& outAlignment,
 atl::Array<avl::Point3D>& diagPointsWorkingSet,
 atl::Array<avl::Point3D>& diagReferencePointsWorkingSet,
 atl::Array<atl::Array<avl::Segment3D>>& diagAttractionSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Point3DGrid&			Data points to be aligned, may contain background clutter.
→	inReferencePoints	const Point3DGrid&			Reference points to align to, may only contain points belonging to the object of interest.
→	inMaxIterationCount	const int	1 – ∞	100	Maximal number of iteration for the algorithm
→	inMatchFraction	const float	0.0 – 1.0	0.1111111111111111f	Defines fraction of input points that is being fitted in every iteration
→	inDiscardFurthestFraction	const float	0.0 – 1.0	0.05f	Fraction of point pairs to be discarded during internal ICP loop. Furthest pairs are discarded, and only in last 10% of algorithm iterations. Useful for handling outliers in the inReferencePoints, as well as gaps/holes in the inPoints data.
←	outAlignedPoints	Point3DGrid&			The aligned input points
←	outAlignment	Matrix&			The transform that aligns best the input points to the reference points
🔍	diagPointsWorkingSet	Array<Point3D>&			inPoints after decimation by inMatchFraction, i.e. points which will be fitted in every iteration
🔍	diagReferencePointsWorkingSet	Array<Point3D>&			inReferencePoints after decimation by inMatchFraction, i.e. points which will be fitted in every iteration
🔍	diagAttractionSegments	Array<Array<Segment3D>>&			Attraction segments from every iteration. Note that the algorithm internally moves inReferencePoints towards inPoints (and returns inverse transformation), so the segments show movement of reference towards data.

Hints

- Usually the **inPoints** Point3DGrid data contains an object with background – a flat plate or some other clutter. The filter handles such cases, however its best to remove this clutter beforehand. Note: The **inReferencePoints** input must contain only points belonging to the object.
- The filter can not be used as a pattern localization tool, as it performs well only when adjustments to be made are relatively small. For problems where large adjustments are needed (especially rotations) the filter may fail.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in AdjustPointGrids3D.

AdjustPointGrids3DGlobal

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Aligns (rotation + translation) a point grid to match best the reference point grid using a global registration algorithm.

Syntax

```
void avl::AdjustPointGrids3DGlobal
(
 const avl::Point3DGrid& inPoints,
 const avl::Point3DGrid& inReferencePoints,
 const int inSampleCount,
 const float inOverlap,
 const float inDeltaCorrection,
 atl::Optional<const avl::TransformLimits3D&> inTransformLimits3D,
 atl::Optional<const float&> inMaxTranslationDistance,
 atl::Optional<const int&> inSeed,
 avl::Point3DGrid& outAlignedPoints,
 avl::Matrix& outAlignment,
 float& outDelta
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Point3DGrid&			Data points to be aligned, may contain background clutter.
→	inReferencePoints	const Point3DGrid&			Reference points to align to, may contain background clutter.
→	inSampleCount	const int	1 – ∞	500	Number of random samples used by the registration algorithm. Recommended values are from 200 to several thousands.
→	inOverlap	const float	0.0 – 1.0	0.8f	Defines the estimated overlap between two input grids (0 = no overlap, 1.0 = every point in inPoints is also in inReferencePoints).
→	inDeltaCorrection	const float	0.0 – ∞	9.3f	Defines the accuracy of the final alignment. With smaller delta the amount of allocated memory increases.
→	inTransformLimits3D	Optional<const TransformLimits3D&>		NIL	Limits the maximum rotation angles and translation along each axis, of the final transform.
→	inMaxTranslationDistance	Optional<const float&>	0.0 – ∞	NIL	Limits the length of the translation vector of the final transform.
→	inSeed	Optional<const int&>		NIL	Seed for a random generator used by the algorithm.
←	outAlignedPoints	Point3DGrid&			The aligned input points.
←	outAlignment	Matrix&			The transform that aligns best the input points to the reference points.
←	outDelta	float&			Returns estimated value of the parameter delta.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in AdjustPointGrids3DGlobal.
DomainError	Parameter inDeltaCorrection in AdjustPointGrids3DGlobal has to be greater than 0.0.

FitPlaneToPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points of the input grid with a plane using the Least Squares method.

Syntax

```
void avl::FitPlaneToPoint3DGrid
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPointGrid	const Point3DGrid&		Input point grid
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outPlane	Plane3D&		Fitted plane
←	outDistances	Optional<Array<float>&>	NIL	Distances of the input grid points to a resulting plane
←	outSignedDistanceSum	Optional<float&>	NIL	Sum of signed distances of the input grid points to a resulting plane
←	outDistanceSum	Optional<float&>	NIL	Sum of distances of the input grid points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>	NIL	Squared distances of the input grid points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>	NIL	Sum of squared distances of the input grid points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No points to fit the plane to in FitPlaneToPoint3DGrid.

FitPlaneToPoint3DGrid_M

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points of the input grid with a plane using selected M-estimator for outlier suppression.

Applications: Finding a locally optimal plane. Good enough when the number of outliers is small.

Syntax

```
void avl::FitPlaneToPoint3DGrid_M
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointGrid	const Point3DGrid&			Input point grid
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inOutlierSuppression	MEstimator::Type			Selects a method for ignoring points being much different from the rest
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialPlane	Optional<const Plane3D&>		NIL	Initial approximation (if available)
←	outPlane	Plane3D&			Fitted plane
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the computed plane
←	outDistances	Optional<Array<float>&>		NIL	Distances of the input grid points to a resulting plane
←	outSignedDistanceSum	Optional<float&>		NIL	Sum of signed distances of the input grid points to a resulting plane
←	outDistanceSum	Optional<float&>		NIL	Sum of distances of the input grid points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>		NIL	Squared distances of the input grid points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>		NIL	Sum of squared distances of the input grid points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**, **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No points to fit the plane to in FitPlaneToPoint3DGrid_M.

GoldenTemplate3D

Header: AVL.h
Namespace: avl
Module: Vision3DPro

Compares points on the input with the golden object. Any significant differences are considered defects.

Syntax

```
void avl::GoldenTemplate3D
(
 const avl::Point3DGrid& inObject,
 const avl::Point3DGrid& inGoldenObject,
 const float inMaxDistance,
 const float inVoxelSize,
 const int inNeighborCount,
 const int inSampleCount,
 const float inDeltaCorrection,
 atl::Optional<const avl::TransformLimits3D&> inTransformLimits3D,
 const bool inRefineWithICP,
 atl::Optional<const float&> inMaxTranslationDistance,
 const float inOverlap,
 atl::Array<avl::Point3D>& outMissing,
 atl::Array<avl::Point3D>& outExcessive,
 avl::Matrix& outAlignment,
 avl::Point3DGrid& diagCleanedGoldenObject,
 avl::Point3DGrid& diagAlignedObject
)
```

Parameters

	Name	Type	Range	Default	Description
→	inObject	const Point3DGrid&			Input Point3DGrid
→	inGoldenObject	const Point3DGrid&			Point3DGrid with the golden object
→	inMaxDistance	const float	0.0 – ∞		Maximal allowed distance between corresponding vertices of the input and the golden object
→	inVoxelSize	const float	0.0 – ∞	0.0f	Defines a voxel size used to subsample both grids.
→	inNeighborCount	const int	1 – ∞	15	Defines number of neighbors used to compute average distances between vertices during noise removal.
→	inSampleCount	const int	1 – ∞	10000	Defines number of samples used by the registration algorithm.
→	inDeltaCorrection	const float	0.0 – ∞	12.0f	Defines the accuracy of the alignment. With smaller delta the amount of allocated memory increases.
→	inTransformLimits3D	Optional<const TransformLimits3D&>		NIL	Limits the maximum rotation angles and translation along each axis, of the final transform.
→	inRefineWithICP	const bool		False	Defines whether the alignment should be refined with ICP.
→	inMaxTranslationDistance	Optional<const float&>	0.0 – ∞	NIL	Limits the length of the translation vector of the final transform.
→	inOverlap	const float	0.0 – 1.0	0.95f	Defines the estimated overlap between two input grids (0 = no overlap, 1.0 = every point in inObject is also in inGoldenObject).
←	outMissing	Array<Point3D>&			Points from the golden object not present in the input object.
←	outExcessive	Array<Point3D>&			Points from the input object not present in the golden object.
←	outAlignment	Matrix&			The transform that aligns best the input object to the golden object.
🔍	diagCleanedGoldenObject	Point3DGrid&			Golden object after subsampling and noise removal.
🔍	diagAlignedObject	Point3DGrid&			Aligned and cleaned input object

Errors

List of possible exceptions:

Error type	Description
DomainError	Grids are empty after noise removal in GoldenTemplate3D.
DomainError	inNeighborCount is larger than the number of valid points in GoldenTemplate3D.
DomainError	Input grid has no valid points in GoldenTemplate3D.
DomainError	Input grid is empty in GoldenTemplate3D.
DomainError	Parameter inDeltaCorrection in GoldenTemplate3D has to be greater than 0.0
DomainError	Parameter inVoxelSize in GoldenTemplate3D has to be greater than or equal to 0.0
DomainError	Pitch limits are out of range. Please use values between -180 and 180.
DomainError	Pitch Max limit should be greater than the min limit.
DomainError	Roll limits are out of range. Please use values between -180 and 180.
DomainError	Roll Max limit should be greater than the min limit.
DomainError	X Translation Max limit should be greater than the min limit.
DomainError	Y Translation Max limit should be greater than the min limit.
DomainError	Yaw limits are out of range. Please use values between -180 and 180.
DomainError	Yaw Max limit should be greater than the min limit.
DomainError	Z Translation Max limit should be greater than the min limit.

Point3DGridDistance

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes distances between two input grids.

Syntax

```
void avl::Point3DGridDistance
(
 const avl::Point3DGrid& inReference,
 const avl::Point3DGrid& inCompare,
 atl::Optional<const avl::Region&> inRoi,
 const float inThreshold,
 atl::Array<avl::Point3D>& outCorrectPoints,
 atl::Array<avl::Point3D>& outIncorrectPoints,
 float& outMaxDistance,
 float& outMinDistance,
 atl::Array<float>& outDistances
)
```

Parameters

	Name	Type	Range	Default	Description
→	inReference	const Point3DGrid&			Reference grid
→	inCompare	const Point3DGrid&			Data points for which the distances will be computed.
→	inRoi	Optional<const Region&>		NIL	Range of points for which the distance will be computed.
→	inThreshold	const float	0.0 – ∞		Defines for each data point a maximum allowed distance to the reference grid.
←	outCorrectPoints	Array<Point3D>&			All data points with distance to the reference grid smaller that the given threshold
←	outIncorrectPoints	Array<Point3D>&			All data points with distance to reference grid greater that the given threshold
←	outMaxDistance	float&			Maximum computed distance
←	outMinDistance	float&			Minimum computed distance
←	outDistances	Array<float>&			All computed distances

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in Point3DGridDistance.
DomainError	Region of interest exceeds an input Point3DGrid in Point3DGridDistance.

Point3DGridRMSE

Header: AVL.h
Namespace: avl
Module: Vision3DPro

Computes point-to-point RMSE between two point grids.

Syntax

```
void avl::Point3DGridRMSE
(
 const avl::Point3DGrid& inReference,
 const avl::Point3DGrid& inPoints,
 double& outRMSE
)
```

Parameters

	Name	Type	Default	Description
→	inReference	const Point3DGrid&		Reference grid
→	inPoints	const Point3DGrid&		Data points for which the RMSE will be computed.
←	outRMSE	double&		Root-mean-square error of distances between inPoints and inReference.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input grid has no valid points in Point3DGridRMSE.
DomainError	Input grid is empty inPoint3DGridRMSE.

RemoveOutliersFromPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DPro

Removes noise from a given Point3DGrid. All points that are too far from their neighbors are removed.

Syntax

```
void avl::RemoveOutliersFromPoint3DGrid
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 const float inStdDevMultiple,
 const int inNeighborCount,
 avl::Point3DGrid& outGrid,
 float& diagThreshold,
 float& diagAverageDistance
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointGrid	const Point3DGrid&			Input Point3DGrid
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inStdDevMultiple	const float	0.0 – ∞	1.5f	Allows to set a threshold based on standard deviation of average distances between points on input.
→	inNeighborCount	const int	1 – ∞	10	Defines number of neighbors used to compute average distances between vertices.
←	outGrid	Point3DGrid&			Cleaned input
🔍	diagThreshold	float&			Threshold used by the algorithm.
🔍	diagAverageDistance	float&			Average distance between input points and their neighborhood

Errors

List of possible exceptions:

Error type	Description
DomainError	inNeighborCount is larger than the number of valid points in RemoveOutliersFromPoint3DGrid.
DomainError	Input grid has no valid points in RemoveOutliersFromPoint3DGrid.
DomainError	Input grid is empty in RemoveOutliersFromPoint3DGrid.

VoxelizePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DPro

Keeps one point from each occupied voxel of a given size. Value of all remaining grid points is set to invalid.

Syntax

```
void avl::VoxelizePoint3DGrid
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 const float inVoxelSize,
 avl::Point3DGrid& outGrid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointGrid	const Point3DGrid&			Input Point3DGrid
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inVoxelSize	const float	0.0 – ∞	0.5f	Defines a voxel size used to subsample the grid.
←	outGrid	Point3DGrid&			Subsampled points

Errors

List of possible exceptions:

Error type	Description
DomainError	Input grid is empty in VoxelizePoint3DGrid.
DomainError	Parameter inVoxelSize in VoxelizePoint3DGrid has to be greater than 0.0

AIL1DcodeFormatToBarcodeFormat

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a AIL1DcodeFormat object to a BarcodeFormat.

Syntax

```
void avl::AIL1DcodeFormatToBarcodeFormat
(
 const avl::AIL1DcodeFormat::Type& inFormat,
 avl::BarcodeFormat::Type& outFormat
)
```

Parameters

	Name	Type	Default	Description
→	inFormat	const AIL1DcodeFormat::Type&		
←	outFormat	BarcodeFormat::Type&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported barcode format type in the conversion from AIL barcode to AVL barcode format.

AnyCameraModelToRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::AnyCameraModelToRectificationTransform
(
 const avl::AnyCameraModel& inModel,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const AnyCameraModel&		
←	outTransform	RectificationTransform&		

Also in AVL Lite

BarcodeFormatToAIL1DcodeFormat

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts BarcodeFormat object to a AIL1DcodeFormat

Syntax

```
void avl::BarcodeFormatToAIL1DcodeFormat
(
 const avl::BarcodeFormat::Type& inFormat,
 avl::AIL1DcodeFormat::Type& outFormat
)
```

Parameters

	Name	Type	Default	Description
→	inFormat	const BarcodeFormat::Type&		
←	outFormat	AIL1DcodeFormat::Type&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported barcode format type in the conversion from AVL barcode to AIL barcode format.

Also in AVL Lite

BoolToHash

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a Bool to a Hash.

Syntax

```
void avl::BoolToHash
(
 const bool inBool,
 avl::Hash& outHash
)
```

Parameters

	Name	Type	Default	Description
→	inBool	const bool		
←	outHash	Hash&		

BoolToPassFailStatus

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a bool value to a pass/fail status.

Syntax

```
void avl::BoolToPassFailStatus
(
 const bool inBool,
 avl::PassFailStatus& outPassFailStatus
)
```

Parameters

	Name	Type	Default	Description
→	inBool	const bool		
←	outPassFailStatus	PassFailStatus&		

Box3DToBox

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a box in 3D to a box in 2D by ignoring its Z coordinates.

Syntax

```
void avl::Box3DToBox
(
 const avl::Box3D& inBox3D,
 avl::Box& outBox2D
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
←	outBox2D	Box&		

BoxToBox3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a box in 2D to a box in 3D.

Syntax

```
void avl::BoxToBox3D
(
 const avl::Box& inBox2D,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBox2D	const Box&		
←	outBox3D	Box3D&		

Also in AVL Lite

BoxToRectangle2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a box to a rectangle.

Syntax

```
void avl::BoxToRectangle2D
(
 const avl::Box& inBox,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outRectangle	Rectangle2D&		

Also in AVL Lite

BoxToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a box to shape region.

Syntax

```
void avl::BoxToShapeRegion
(
 const avl::Box& inBox,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

BoxToShapeRegionDeprecated

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a box to a shape region.

Syntax

```
void avl::BoxToShapeRegionDeprecated
(
 const avl::Box& inBox,
 avl::ShapeRegionDeprecated& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outShapeRegion	ShapeRegionDeprecated&		

Circle2DToCircle3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a circle in 2D to a circle in 3D.

Syntax

```
void avl::Circle2DToCircle3D
(
 const avl::Circle2D& inCircle2D,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle2D	const Circle2D&		
←	outCircle3D	Circle3D&		

Also in AVL Lite

Circle2DToEllipse2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a circle to an ellipse.

Syntax

```
void avl::Circle2DToEllipse2D
(
 const avl::Circle2D& inCircle,
 avl::Ellipse2D& outEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outEllipse	Ellipse2D&		

Also in AVL Lite

Circle2DToRing2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a circle to a full circle ring.

Syntax

```
void avl::Circle2DToRing2D
(
 const avl::Circle2D& inCircle,
 avl::Ring2D& outRing
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outRing	Ring2D&		

Also in AVL Lite

Circle2DToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a circle to region of interest.

Syntax

```
void avl::Circle2DToShapeRegion
(
 const avl::Circle2D& inCircle,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

Circle2DToShapeRegionDeprecated

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a circle to a shape region.

Syntax

```
void avl::Circle2DToShapeRegionDeprecated
(
 const avl::Circle2D& inCircle,
 avl::ShapeRegionDeprecated& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outShapeRegion	ShapeRegionDeprecated&		

Circle3DToCircle2D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a circle in 3D to a circle in 2D by ignoring its Z coordinates and tilt.

Syntax

```
void avl::Circle3DToCircle2D
(
 const avl::Circle3D& inCircle3D,
 avl::Circle2D& outCircle2D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
←	outCircle2D	Circle2D&		

DeepModelToClassifyObjectModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and ClassifyObjectModelDirectory

Syntax

```
void avl::DeepModelToClassifyObjectModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::ClassifyObjectModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	ClassifyObjectModelDirectory&		

DeepModelToDetectAnomalies1ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and DetectAnomalies1ModelDirectory

Syntax

```
void avl::DeepModelToDetectAnomalies1ModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::DetectAnomalies1ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	DetectAnomalies1ModelDirectory&		

DeepModelToDetectAnomalies2ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and DetectAnomalies2ModelDirectory

Syntax

```
void avl::DeepModelToDetectAnomalies2ModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::DetectAnomalies2ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	DetectAnomalies2ModelDirectory&		

DeepModelToDetectFeaturesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and DetectFeaturesModelDirectory

Syntax

```
void avl::DeepModelToDetectFeaturesModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::DetectFeaturesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	DetectFeaturesModelDirectory&		

DeepModelToLocatePointsModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and LocatePointsModelDirectory

Syntax

```
void avl::DeepModelToLocatePointsModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::LocatePointsModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	LocatePointsModelDirectory&		

DeepModelToSegmentInstancesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between DeepModel and SegmentInstancesModelDirectory

Syntax

```
void avl::DeepModelToSegmentInstancesModelDirectory
(
 const avl::DeepModel& inDeepModel,
 avl::SegmentInstancesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDeepModel	const DeepModel&		
←	outModelDirectory	SegmentInstancesModelDirectory&		

DirectoryToClassifyObjectModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and ClassifyObjectModelDirectory

Syntax

```
void avl::DirectoryToClassifyObjectModelDirectory
(
 const atl::Directory& inDirectory,
 avl::ClassifyObjectModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	ClassifyObjectModelDirectory&		

DirectoryToDetectAnomalies1ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and DetectAnomalies1ModelDirectory

Syntax

```
void avl::DirectoryToDetectAnomalies1ModelDirectory
(
 const atl::Directory& inDirectory,
 avl::DetectAnomalies1ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	DetectAnomalies1ModelDirectory&		

DirectoryToDetectAnomalies2ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and DetectAnomalies2ModelDirectory

Syntax

```
void avl::DirectoryToDetectAnomalies2ModelDirectory
(
 const atl::Directory& inDirectory,
 avl::DetectAnomalies2ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	DetectAnomalies2ModelDirectory&		

DirectoryToDetectFeaturesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and DetectFeaturesModelDirectory

Syntax

```
void avl::DirectoryToDetectFeaturesModelDirectory
(
 const atl::Directory& inDirectory,
 avl::DetectFeaturesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	DetectFeaturesModelDirectory&		

DirectoryToLocateObjectsModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and LocateObjectsModelDirectory

Syntax

```
void avl::DirectoryToLocateObjectsModelDirectory
(
 const atl::Directory& inDirectory,
 avl::LocateObjectsModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	LocateObjectsModelDirectory&		

DirectoryToLocatePointsModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and LocatePointsModelDirectory

Syntax

```
void avl::DirectoryToLocatePointsModelDirectory
(
 const atl::Directory& inDirectory,
 avl::LocatePointsModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	LocatePointsModelDirectory&		

DirectoryToSegmentInstancesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and SegmentInstancesModelDirectory

Syntax

```
void avl::DirectoryToSegmentInstancesModelDirectory
(
 const atl::Directory& inDirectory,
 avl::SegmentInstancesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inDirectory	const Directory&		
←	outModelDirectory	SegmentInstancesModelDirectory&		

Also in AVL Lite

Ellipse2DToRectangle2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an ellipse to a rectangle.

Syntax

```
void avl::Ellipse2DToRectangle2D
(
 const avl::Ellipse2D& inEllipse,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inEllipse	const Ellipse2D&		
←	outRectangle	Rectangle2D&		

Also in AVL Lite

Ellipse2DToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an ellipse to region of interest.

Syntax

```
void avl::Ellipse2DToShapeRegion
(
 const avl::Ellipse2D& inEllipse,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inEllipse	const Ellipse2D&		
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

Gap1DToSegment2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a gap to a segment.

Syntax

```
void avl::Gap1DToSegment2D
(
 const avl::Gap1D& inGap,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inGap	const Gap1D&		
←	outSegment	Segment2D&		

Also in AVL Lite

HeatmapToImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a heatmap to an image.

Syntax

```
void avl::HeatmapToImage
(
 const avl::Heatmap& inHeatmap,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inHeatmap	const Heatmap&		
←	outImage	Image&		Output image

Also in AVL Lite

ImageToImageFormat

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an image to an image format.

Syntax

```
void avl::ImageToImageFormat
(
 const avl::Image& inImage,
 avl::ImageFormat& outImageFormat
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImageFormat	ImageFormat&		

ImageToSize

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an image to a size.

Syntax

```
void avl::ImageToSize
(
 const avl::Image& inImage,
 avl::Size& outSize
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outSize	Size&		

Also in AVL Lite

IntegerToHash

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an Integer to a Hash.

Syntax

```
void avl::IntegerToHash
(
 const int inInteger,
 avl::Hash& outHash
)
```

Parameters

	Name	Type	Default	Description
→	inInteger	const int		
←	outHash	Hash&		

Also in AVL Lite

IntegerToPixel

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an integer value to pixel.

Syntax

```
void avl::IntegerToPixel
(
 const int inValue,
 avl::Pixel& outPixel
)
```

Parameters

	Name	Type	Default	Description
→	inValue	const int		
←	outPixel	Pixel&		

Line2DToLine3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a line in 2D to a line in 3D.

Syntax

```
void avl::Line2DToLine3D
(
 const avl::Line2D& inLine2D,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine2D	const Line2D&		
←	outLine3D	Line3D&		

Line3DToLine2D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a line in 3D to a line in 2D by ignoring its Z coordinates.

Syntax

```
void avl::Line3DToLine2D
(
 const avl::Line3D& inLine3D,
 avl::Line2D& outLine2D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
←	outLine2D	Line2D&		

LineScanCameraModelToAnyCameraModel

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::LineScanCameraModelToAnyCameraModel
(
 const avl::LineScanCameraModel& inModel,
 avl::AnyCameraModel& outModel
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const LineScanCameraModel&		
←	outModel	AnyCameraModel&		

LineScanCameraModelToRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::LineScanCameraModelToRectificationTransform
(
 const avl::LineScanCameraModel& inModel,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const LineScanCameraModel&		
←	outTransform	RectificationTransform&		

Also in AVL Lite

LocationArrayToPoint2DArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an array of locations to an array of points.

Syntax

```
void avl::LocationArrayToPoint2DArray
(
 const atl::Array<avl::Location>& inLocationArray,
 atl::Array<avl::Point2D>& outPointArray
)
```

Parameters

	Name	Type	Default	Description
→	inLocationArray	const Array<Location>&		
←	outPointArray	Array<Point2D>&		

Also in AVL Lite

LocationToPoint2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a location to its center point.

Syntax

```
void avl::LocationToPoint2D
(
 const avl::Location& inLocation,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inLocation	const Location&		
←	outPoint	Point2D&		

MatrixToRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::MatrixToRectificationTransform
(
 const avl::Matrix& inHomography,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inHomography	const Matrix&		
←	outTransform	RectificationTransform&		

Errors

List of possible exceptions:

Error type	Description
DomainError	inHomography matrix must be a 3x3 matrix

Also in **AVL Lite**

PassFailStatusToBool

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a pass/fail status to a bool value.

Syntax

```
void avl::PassFailStatusToBool
(
 const avl::PassFailStatus& inPassFailStatus,
 bool& outBool
)
```

Parameters

	Name	Type	Default	Description
→	inPassFailStatus	const PassFailStatus&		
←	outBool	bool&		

Also in AVL Lite

PassFailStatusToHash

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a PassFailStatus object to a Hash.

Syntax

```
void avl::PassFailStatusToHash
(
 const avl::PassFailStatus& inPassFailStatus,
 avl::Hash& outHash
)
```

Parameters

	Name	Type	Default	Description
→	inPassFailStatus	const PassFailStatus&		
←	outHash	Hash&		

Also in AVL Lite

PathToPoint2DArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a path to an array of points.

Syntax

```
void avl::PathToPoint2DArray
(
 const avl::Path& inPath,
 atl::Array<avl::Point2D >& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outPoints	Array<Point2D >&		

PinholeCameraModelToAnyCameraModel

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::PinholeCameraModelToAnyCameraModel
(
 const avl::PinholeCameraModel& inModel,
 avl::AnyCameraModel& outModel
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const PinholeCameraModel&		
←	outModel	AnyCameraModel&		

PinholeCameraModelToRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::PinholeCameraModelToRectificationTransform
(
 const avl::PinholeCameraModel& inModel,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const PinholeCameraModel&		
←	outTransform	RectificationTransform&		

Also in AVL Lite

PixelToWebHMIColor

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an image pixel to WebHMI color.

Syntax

```
void avl::PixelToWebHMIColor
(
 const avl::Pixel& inPixel,
 avl::WebHMIColor& outColor
)
```

Parameters

	Name	Type	Default	Description
→	inPixel	const Pixel&		
←	outColor	WebHMIColor&		

Also in AVL Lite

Point2DArrayToLocationArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an array of points to an array of locations.

Syntax

```
void avl::Point2DArrayToLocationArray
(
 const atl::Array<avl::Point2D>& inPointArray,
 atl::Array<avl::Location>& outLocationArray
)
```

Parameters

	Name	Type	Default	Description
→	inPointArray	const Array<Point2D>&		
←	outLocationArray	Array<Location>&		

Point2DToLocation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a point to a location its contained within.

Syntax

```
void avl::Point2DToLocation
(
 const avl::Point2D& inPoint,
 avl::Location& outLocation
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
←	outLocation	Location&		

Point2DToPoint3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a point in 2D to a point in 3D.

Syntax

```
void avl::Point2DToPoint3D
(
 const avl::Point2D& inPoint2D,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint2D	const Point2D&		
←	outPoint3D	Point3D&		

Point3DArrayToPoint2DArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts an array of points in 3D to an array of points in 2D by ignoring their Z coordinates.

Syntax

```
void avl::Point3DArrayToPoint2DArray
(
 const atl::Array<avl::Point3D>& inPoint3DArray,
 atl::Array<avl::Point2D>& outPoint2DArray
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DArray	const Array<Point3D>&		
←	outPoint2DArray	Array<Point2D>&		

Point3DGridToPoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Converts a grid of points to an array of points removing nonexistent ones.

Syntax

```
void avl::Point3DGridToPoint3DArray
(
 const avl::Point3DGrid& inPoint3DGrid,
 atl::Array<avl::Point3D>& outPoint3DArray
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
←	outPoint3DArray	Array<Point3D>&		

Point3DToPoint2D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a point in 3D to a point in 2D by ignoring its Z coordinate.

Syntax

```
void avl::Point3DToPoint2D
(
 const avl::Point3D& inPoint3D,
 avl::Point2D& outPoint2D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
←	outPoint2D	Point2D&		

Also in AVL Lite

ProfileToPoint2DArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a profile to an array of points.

Syntax

```
void avl::ProfileToPoint2DArray
(
 const avl::Profile& inProfile,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
←	outPoints	Array<Point2D>&		

Also in AVL Lite

ProfileToRealArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a profile to an array of real numbers.

Syntax

```
void avl::ProfileToRealArray
(
 const avl::Profile& inProfile,
 atl::Array<float>& outArray
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
←	outArray	Array<float>&		

Also in AVL Lite

RealArrayToPixelArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an array of real values to an array of pixels.

Syntax

```
void avl::RealArrayToPixelArray
(
 const atl::Array<float>& inValues,
 atl::Array<avl::Pixel>& outPixels
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
←	outPixels	Array<Pixel>&		

Also in AVL Lite

RealArrayToProfile

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an array of real numbers to a profile.

Syntax

```
void avl::RealArrayToProfile
(
 const atl::Array<float>& inArray,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inArray	const Array<float>&		
←	outProfile	Profile&		Output profile

Also in AVL Lite

RealToPixel

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a real value to pixel.

Syntax

```
void avl::RealToPixel
(
 const float inValue,
 avl::Pixel& outPixel
)
```

Parameters

	Name	Type	Default	Description
→	inValue	const float		
←	outPixel	Pixel&		

Also in AVL Lite

Rectangle2DToEllipse2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a rectangle to an ellipse .

Syntax

```
void avl::Rectangle2DToEllipse2D
(
 const avl::Rectangle2D& inRectangle,
 avl::Ellipse2D& outEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outEllipse	Ellipse2D&		

Also in AVL Lite

Rectangle2DToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a rectangle to region of interest.

Syntax

```
void avl::Rectangle2DToShapeRegion
(
 const avl::Rectangle2D& inRectangle,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

Rectangle2DToShapeRegionDeprecated

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a rectangle to a shape region.

Syntax

```
void avl::Rectangle2DToShapeRegionDeprecated
(
 const avl::Rectangle2D& inRectangle,
 avl::ShapeRegionDeprecated& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outShapeRegion	ShapeRegionDeprecated&		

Also in AVL Lite

RegionToImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a region to an image.

Syntax

```
void avl::RegionToImage
(
 const avl::Region& inRegion,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outImage	Image&		Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Also in AVL Lite

RegionToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a region to region of interest.

Syntax

```
void avl::RegionToShapeRegion
(
 const avl::Region& inRegion,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

Ring2DToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a ring to region of interest.

Syntax

```
void avl::Ring2DToShapeRegion
(
 const avl::Ring2D& inRing,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRing	const Ring2D&		
←	outShapeRegion	ShapeRegion&		

Also in AVL Lite

Segment2DToLine2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a segment to a line.

Syntax

```
void avl::Segment2DToLine2D
(
 const avl::Segment2D& inSegment,
 avl::Line2D& outLine
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outLine	Line2D&		

Segment2DToPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a segment to a path.

Syntax

```
void avl::Segment2DToPath
(
 const avl::Segment2D& inSegment,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outPath	Path&		Output path

Segment2DToSegment3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a segment in 2D to a segment in 3D.

Syntax

```
void avl::Segment2DToSegment3D
(
 const avl::Segment2D& inSegment2D,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment2D	const Segment2D&		
←	outSegment3D	Segment3D&		

Segment3DToLine3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a segment in 3D to a line in 3D.

Syntax

```
void avl::Segment3DToLine3D
(
 const avl::Segment3D& inSegment,
 avl::Line3D& outLine
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment3D&		
←	outLine	Line3D&		

Segment3DToPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a segment in 3D to a path in 2D by ignoring its Z coordinates.

Syntax

```
void avl::Segment3DToPath
(
 const avl::Segment3D& inSegment3D,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outPath	Path&		Output path

Segment3DToSegment2D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a segment in 3D to a segment in 2D by ignoring its Z coordinates.

Syntax

```
void avl::Segment3DToSegment2D
(
 const avl::Segment3D& inSegment3D,
 avl::Segment2D& outSegment2D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outSegment2D	Segment2D&		

Also in AVL Lite

SparseImageToRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a sparse region to a region.

Syntax

```
void avl::SparseImageToRegion
(
 const avl::SparseImage& inSparseImage,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inSparseImage	const SparseImage&		
←	outRegion	Region&		Output region

StringLabelToString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a StringLabel object to a String.

Syntax

```
void avl::StringLabelToString
(
 const avl::StringLabel& inStringLabel,
 atl::String& outString
)
```

Parameters

	Name	Type	Default	Description
→	inStringLabel	const StringLabel&		
←	outString	String&		

StringToClassifyObjectModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between Directory and ClassifyObjectModelDirectory

Syntax

```
void avl::StringToClassifyObjectModelDirectory
(
 const atl::String& inString,
 avl::ClassifyObjectModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	ClassifyObjectModelDirectory&		

StringToDetectAnomalies1ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and DetectAnomalies1ModelDirectory

Syntax

```
void avl::StringToDetectAnomalies1ModelDirectory
(
 const atl::String& inString,
 avl::DetectAnomalies1ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	DetectAnomalies1ModelDirectory&		

StringToDetectAnomalies2ModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and DetectAnomalies2ModelDirectory

Syntax

```
void avl::StringToDetectAnomalies2ModelDirectory
(
 const atl::String& inString,
 avl::DetectAnomalies2ModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	DetectAnomalies2ModelDirectory&		

StringToDetectFeaturesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and DetectFeaturesModelDirectory

Syntax

```
void avl::StringToDetectFeaturesModelDirectory
(
 const atl::String& inString,
 avl::DetectFeaturesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	DetectFeaturesModelDirectory&		

StringToGrammarRulesPattern

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and GrammarRulesPattern

Syntax

```
void avl::StringToGrammarRulesPattern
(
 const atl::String& inString,
 avl::GrammarRulesPattern& outGrammarRulesPattern
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outGrammarRulesPattern	GrammarRulesPattern&		

StringToLocateObjectsModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and LocateObjectsModelDirectory

Syntax

```
void avl::StringToLocateObjectsModelDirectory
(
 const atl::String& inString,
 avl::LocateObjectsModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	LocateObjectsModelDirectory&		

StringToLocatePointsModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and LocatePointsModelDirectory

Syntax

```
void avl::StringToLocatePointsModelDirectory
(
 const atl::String& inString,
 avl::LocatePointsModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	LocatePointsModelDirectory&		

StringToSegmentInstancesModelDirectory

Header: AVL.h
Namespace: avl
Module: DL_Common

Conversion between String and SegmentInstancesModelDirectory

Syntax

```
void avl::StringToSegmentInstancesModelDirectory
(
 const atl::String& inString,
 avl::SegmentInstancesModelDirectory& outModelDirectory
)
```

Parameters

	Name	Type	Default	Description
→	inString	const String&		
←	outModelDirectory	SegmentInstancesModelDirectory&		

Stripe1DToSegment2D

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a stripe to a segment.

Syntax

```
void avl::Stripe1DToSegment2D
(
 const avl::Stripe1D& inStripe,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inStripe	const Stripe1D&		
←	outSegment	Segment2D&		

SurfaceFormatToSurfaceCoordinatesFormat

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface format to a surface coordinates format.

Syntax

```
void avl::SurfaceFormatToSurfaceCoordinatesFormat
(
 const avl::SurfaceFormat& inSurfaceFormat,
 avl::SurfaceCoordinatesFormat& outSurfaceCoordinatesFormat
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceFormat	const SurfaceFormat&		
←	outSurfaceCoordinatesFormat	SurfaceCoordinatesFormat&		

SurfaceToImage

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface object to an image.

Syntax

```
void avl::SurfaceToImage
(
 const avl::Surface& inSurface,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outImage	Image&		Output image

SurfaceToPoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface object to an array of points removing nonexistent ones.

Syntax

```
void avl::SurfaceToPoint3DArray
(
 const avl::Surface& inSurface,
 atl::Array<avl::Point3D>& outPoint3DArray
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outPoint3DArray	Array<Point3D>&		Output point array

SurfaceToPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface object to a grid of points.

Syntax

```
void avl::SurfaceToPoint3DGrid
(
 const avl::Surface& inSurface,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outPoint3DGrid	Point3DGrid&		Output point grid

SurfaceToSurfaceCoordinatesFormat

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface to a surface coordinates format.

Syntax

```
void avl::SurfaceToSurfaceCoordinatesFormat
(
 const avl::Surface& inSurface,
 avl::SurfaceCoordinatesFormat& outSurfaceCoordinatesFormat
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		
←	outSurfaceCoordinatesFormat	SurfaceCoordinatesFormat&		

SurfaceToSurfaceFormat

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a surface to a surface format.

Syntax

```
void avl::SurfaceToSurfaceFormat
(
 const avl::Surface& inSurface,
 avl::SurfaceFormat& outSurfaceFormat
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		
←	outSurfaceFormat	SurfaceFormat&		

TelecentricCameraModelToAnyCameraModel

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::TelecentricCameraModelToAnyCameraModel
(
 const avl::TelecentricCameraModel& inModel,
 avl::AnyCameraModel& outModel
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const TelecentricCameraModel&		
←	outModel	AnyCameraModel&		

TelecentricCameraModelToRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Conversion

Syntax

```
void avl::TelecentricCameraModelToRectificationTransform
(
 const avl::TelecentricCameraModel& inModel,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inModel	const TelecentricCameraModel&		
←	outTransform	RectificationTransform&		

Also in AVL Lite

ValueLimitsToValueLimits_f64

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts value limits of different types.

Syntax

```
void avl::ValueLimitsToValueLimits_f64
(
 const avl::ValueLimits& inValueLimits,
 avl::ValueLimits_f64& outValueLimits_f64
)
```

Parameters

	Name	Type	Default	Description
→	inValueLimits	const ValueLimits&		
←	outValueLimits_f64	ValueLimits_f64&		

Also in AVL Lite

ValueLimits_f64ToValueLimits

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts value limits of different types.

Syntax

```
void avl::ValueLimits_f64ToValueLimits
(
 const avl::ValueLimits_f64& inValueLimits_f64,
 avl::ValueLimits& outValueLimits
)
```

Parameters

	Name	Type	Default	Description
→	inValueLimits_f64	const ValueLimits_f64&		
←	outValueLimits	ValueLimits&		

Vector2DToVector3D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a vector in 2D to a vector in 3D.

Syntax

```
void avl::Vector2DToVector3D
(
 const avl::Vector2D& inVector2D,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inVector2D	const Vector2D&		
←	outVector3D	Vector3D&		

Vector3DToVector2D

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a vector in 3D to a vector in 2D by ignoring its Z coordinates.

Syntax

```
void avl::Vector3DToVector2D
(
 const avl::Vector3D& inVector3D,
 avl::Vector2D& outVector2D
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
←	outVector2D	Vector2D&		

Also in AVL Lite

WebHMIColorToString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a WebHMI color to HTML color notation.

Syntax

```
void avl::WebHMIColorToString
(
 const avl::WebHMIColor& inColor,
 atl::String& outHtmlNotation
)
```

Parameters

	Name	Type	Default	Description
→	inColor	const WebHMIColor&		
←	outHtmlNotation	String&		

Also in AVL Lite

BoolToXSightIOLevel

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Converts port level to a bool.

Syntax

```
void avl::BoolToXSightIOLevel
(
 bool inBool,
 avl::XSightIOLevel::Type& outIOLevel
)
```

Parameters

	Name	Type	Default	Description
→	inBool	bool		
←	outIOLevel	XSightIOLevel::Type&		

XSightIOLevelToBool

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Converts port level to a bool.

Syntax

```
void avl::XSightIOLevelToBool
(
 avl::XSightIOLevel::Type inIOLevel,
 bool& outBool
)
```

Parameters

	Name	Type	Default	Description
→	inIOLevel	XSightIOLevel::Type		
←	outBool	bool&

AlignArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves an arc from a local coordinate system to the absolute one.

Applications: Required when there is an arc defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignArc
(
 const avl::Arc2D& inArc,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Arc2D& outAlignedArc
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outAlignedArc**

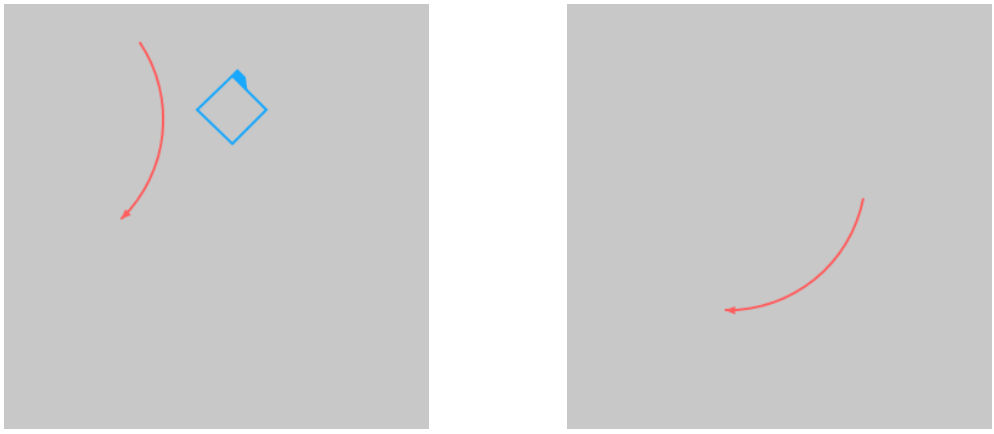
Read more about In-place Computation.

Description

AlignArc aligns the **inArc** to the **inAlignment** coordinate system. The input arc is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples



***AlignArc** performed on the sample arc. The **inAlignment** is drawn on the first image in blue.*

See Also

- RotateArc - Rotates an arc clockwise around center point.
- TranslateArc - Translates an arc by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

AlignCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a circle from a local coordinate system to the absolute one.

Applications: Required when there is a circle defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignCircle
(
 const avl::Circle2D& inCircle,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Circle2D& outAlignedCircle
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedCircle	Circle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle** and **outAlignedCircle**

Read more about In-place Computation.

Description

AlignCircle aligns the **inCircle** to the **inAlignment** coordinate system. The input circle is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples

AlignCircle *performed on the sample circle. The* ***inAlignment*** *is drawn on the first image in blue.*

See Also

- RotateCircle - Rotates a circle clockwise around a center point.
- TranslateCircle - Translates a circle by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

AlignCoordinateSystem

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a nested coordinate system from its local coordinate system to the absolute one.

Applications: This filter is required e.g. when we first locate an object and then we locate its parts within it.

Syntax

```
void avl::AlignCoordinateSystem
(
 const avl::CoordinateSystem2D& inCoordinateSystem,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::CoordinateSystem2D& outAlignedCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inCoordinateSystem	const CoordinateSystem2D&		
→	inAlignment	const CoordinateSystem2D&		
→	inInverse	bool		Switches to the inverse operation
←	outAlignedCoordinateSystem	CoordinateSystem2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCoordinateSystem** and **outAlignedCoordinateSystem**, **inAlignment** and **outAlignedCoordinateSystem**

Read more about In-place Computation.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

AlignLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a line from a local coordinate system to the absolute one.

Applications: Required when there is a line defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignLine
(
 const avl::Line2D& inLine,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Line2D& outAlignedLine
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedLine	Line2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine** and **outAlignedLine**

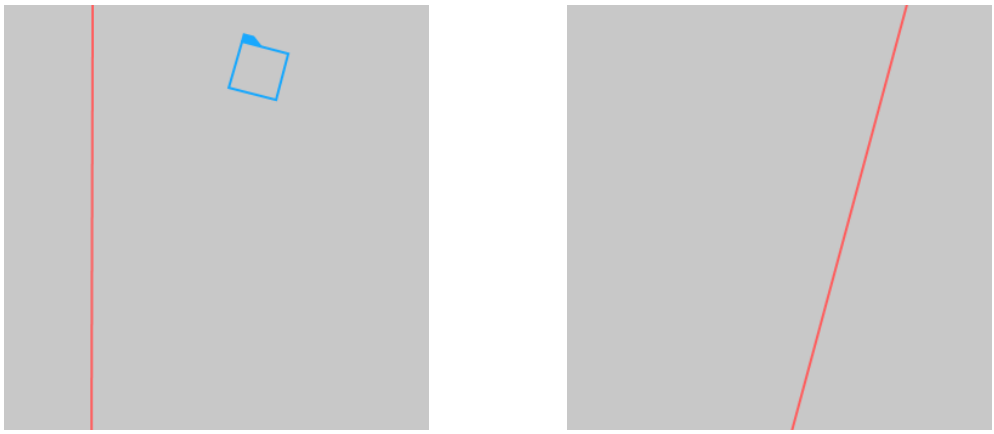
Read more about In-place Computation.

Description

AlignLine aligns the **inLine** to the **inAlignment** coordinate system. The input line is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples



***AlignLine** performed on the sample line. The **inAlignment** is drawn on the first image in blue.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in AlignLine.

See Also

- RotateLine – Rotates a line clockwise around a center point.
- TranslateLine – Translates a line by a vector.
- AlignPath – Moves a path from a local coordinate system to the absolute one.

AlignPoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a point from a local coordinate system to the absolute one.

Applications: Required when there is a point defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignPoint
(
 const avl::Point2D& inPoint,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Point2D& outAlignedPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedPoint	Point2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint** and **outAlignedPoint**

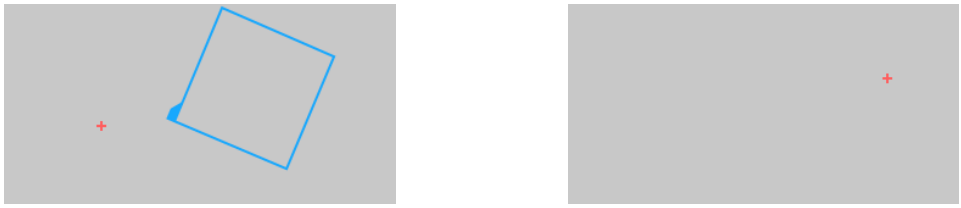
Read more about In-place Computation.

Description

AlignPoint aligns the **inPoint** to the **inAlignment** coordinate system. The input point is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples



AlignPoint *performed on the sample point. The* ***inAlignment*** *is drawn on the first image in blue.*

See Also

- RotatePoint - Rotates a point clockwise around a center point.
- TranslatePoint - Translates a point by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

AlignPointArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves an array of points from a local coordinate system to the absolute one.

Applications: Required when there are points defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignPointArray
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 atl::Array<avl::Point2D>& outAlignedPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedPoints	Array<Point2D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints** and **outAlignedPoints**

Read more about In-place Computation.

AlignRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a rectangle from a local coordinate system to the absolute one.

Applications: Required when there is a rectangle defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignRectangle
(
 const avl::Rectangle2D& inRectangle,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Rectangle2D& outAlignedRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outAlignedRectangle**

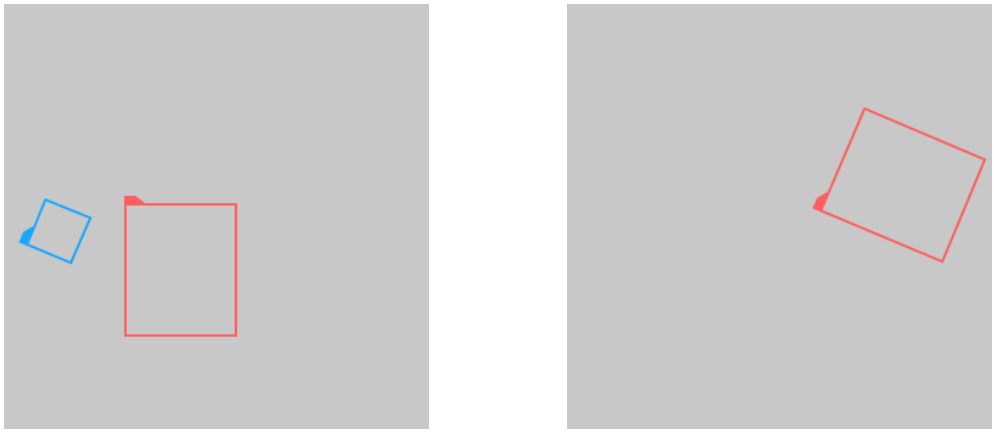
Read more about In-place Computation.

Description

AlignRectangle aligns the **inRectangle** to the **inAlignment** coordinate system. The input rectangle is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples



AlignRectangle *performed on the sample rectangle. The* ***inAlignment*** *is drawn on the first image in blue.*

See Also

- RotateRectangle - Rotates a rectangle clockwise around a center point.
- TranslateRectangle - Translates a rectangle by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

AlignSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a segment from a local coordinate system to the absolute one.

Applications: Required when there is a segment defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignSegment
(
 const avl::Segment2D& inSegment,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Segment2D& outAlignedSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedSegment	Segment2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outAlignedSegment**

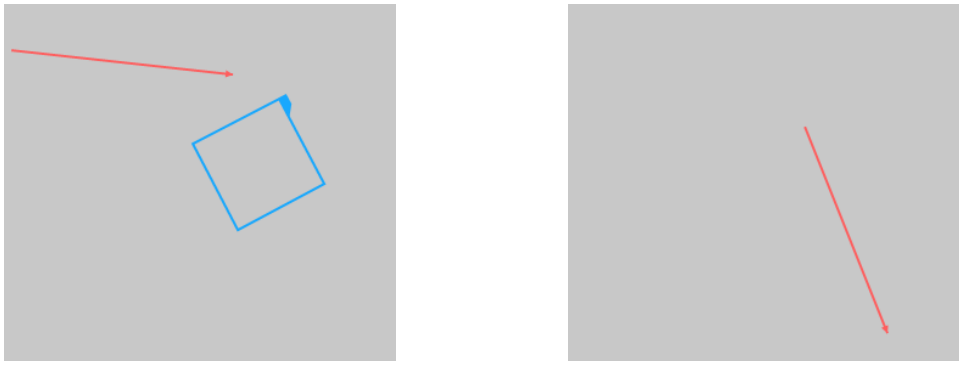
Read more about In-place Computation.

Description

AlignSegment aligns the **inSegment** to the **inAlignment** coordinate system. The input segment is translated, rotated and scaled.

The **inAlignment** is usually a coordinate system found by some template matching algorithm.

Examples



***AlignSegment** performed on the sample segment. The **inAlignment** is drawn on the first image in blue.*

See Also

- RotateSegment - Rotates a segment clockwise around a center point.
- TranslateSegment - Translates a segment by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

Also in AVL Lite

InflateRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enlarges a rectangle by a given margin.

Syntax

```
void avl::InflateRectangle
(
 const avl::Rectangle2D& inRectangle,
 float inMargin,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inMargin	float		
←	outRectangle	Rectangle2D&		

Also in AVL Lite

InvertCoordinateSystem

Header: AVL.h
Namespace: avl
Module: FoundationLite

Inverts a coordinate system.

Syntax

```
void avl::InvertCoordinateSystem
(
 const avl::CoordinateSystem2D& inCoordinateSystem,
 avl::CoordinateSystem2D& outInvertedCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inCoordinateSystem	const CoordinateSystem2D&		
←	outInvertedCoordinateSystem	CoordinateSystem2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCoordinateSystem** and **outInvertedCoordinateSystem**

Read more about In-place Computation.

Also in AVL Lite

PointAlongArc

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms a point to a coordinate system in which the 'axis' arc is vertical or horizontal.

Applications: Usually used to revert an ImageAlongArc transformation.

Syntax

```
void avl::PointAlongArc
(
 const avl::Point2D& inPoint,
 const avl::Arc2D& inAxis,
 avl::Axis::Type inAxisType,
 float inAxisCoordinate,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		Input point
→	inAxis	const Arc2D&		Input axis arc
→	inAxisType	Axis::Type	Y	Type of axis the input axis arc is parallel to
→	inAxisCoordinate	float	0.0f	Coordinate of the axis arc
→	inInverse	bool	True	Switches to the inverse operation
←	outPoint	Point2D&		Transformed point

Description

This operation transforms a point – **inPoint** – between two coordinate systems: the one linked with 'axis' arc **inAxis** and the original one. Direction of this conversion is based on **inInverse** value:

- if it is true, **inPoint** is converted *to* original coordinate system
- if it is false, **inPoint** is converted *from* original coordinate system

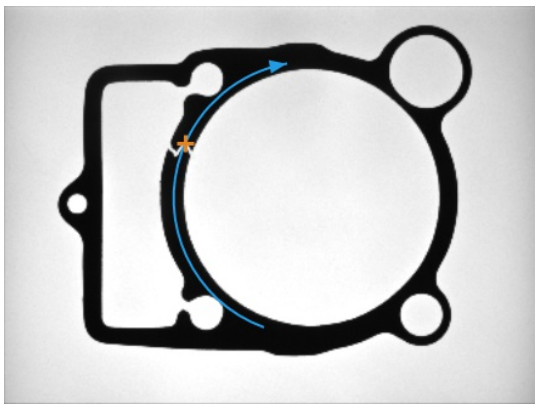
Coordinate system linked with **inAxis** is some transformation of the original one, satisfying these conditions:

- 'axis' arc is represented as a straight line
- 'axis' arc is horizontal if **inAxisType** is set to X or vertical if **inAxisType** is set to Y
- if **inAxisType** is set to X, the Y coordinate of 'axis' arc is equal to **inAxisCoordinate**. If **inAxisType** is set to Y, the X coordinate of 'axis' arc is equal to **inAxisCoordinate**

Hints

- If this filter is used to reverse **ImageAlongArc** transformation you should set **inAxis** and **inAxisType** to the same values as corresponding ones in **ImageAlongArc**. **inAxisCoordinate** should be set to a half of **ImageAlongArc.inScanWidth**.

Examples



ImageAlongArc *performed on the sample image with* ***inAxisType*** *= X and* ***inScanWidth*** *= 50. Point marked with green cross on the output image was calculated by* ***ScanSingleEdge****. Original point (marked with blue cross) was calculated using* ***PointAlongArc*** *with* ***inAxisType*** *= X,* ***inAxisCoordinate*** *= 25,* ***inInverse*** *= true and position of detected point.* ***ImageAlongArc*** *and* ***PointAlongArc*** *used the same arc for transformations.*

See Also

- ImageAlongArc – Creates an image from pixels traversed along an arc.
- PathAlongArc – Transforms a path to a coordinate system in which the 'axis' arc is vertical or horizontal.
- PointAlongPath – Transforms a point to a coordinate system in which the 'axis' path is vertical or horizontal.

PointAlongPath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms a point to a coordinate system in which the 'axis' path is vertical or horizontal.

Applications: Usually used to revert an ImageAlongPath transformation.

Syntax

```
void avl::PointAlongPath
(
 const avl::Point2D& inPoint,
 const avl::Path& inAxis,
 avl::Axis::Type inAxisType,
 float inAxisCoordinate,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		Input point
→	inAxis	const Path&		Input axis path
→	inAxisType	Axis::Type	Y	Type of axis the input axis path is parallel to
→	inAxisCoordinate	float	0.0f	Coordinate of the axis path
→	inInverse	bool	True	Switches to the inverse operation
←	outPoint	Point2D&		Transformed point

Description

This operation transforms a point – **inPoint** – between two coordinate systems: the one linked with 'axis' path **inAxis** and the original one. Direction of this conversion is based on **inInverse** value:

- if it is true, **inPoint** is converted *to* original coordinate system
- if it is false, **inPoint** is converted *from* original coordinate system

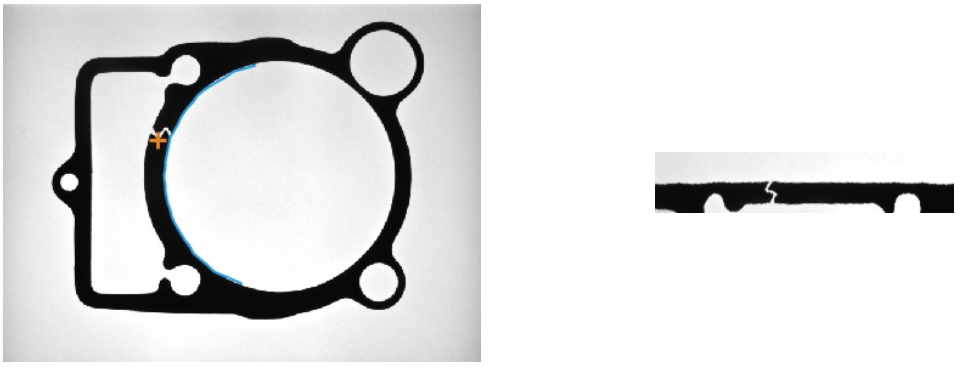
Coordinate system linked with **inAxis** is some transformation of the original one, satisfying these conditions:

- 'axis' path is represented as a straight line
- 'axis' path is horizontal if **inAxisType** is set to X or vertical if **inAxisType** is set to Y
- if **inAxisType** is set to X, the Y coordinate of 'axis' path is equal to **inAxisCoordinate**. If **inAxisType** is set to Y, the X coordinate of 'axis' path is equal to **inAxisCoordinate**

Hints

- If this filter is used to reverse **ImageAlongPath** transformation you should set **inAxis** and **inAxisType** to the same values as corresponding ones in **ImageAlongPath**. **inAxisCoordinate** should be set to a half of **ImageAlongPath.inScanWidth**.

Examples



ImageAlongPath *performed on the sample image with* ***inAxisType*** *= X,* ***inScanWidth*** *= 50 and path marked with blue. Point marked with blue cross on the output image was calculated by* ***ScanSingleEdge****. Original point (marked with orange cross) was calculated using* ***PointAlongPath*** *with* ***inAxisType*** *= X,* ***inAxisCoordinate*** *= 25,* ***inInverse*** *= true and position of detected point.* ***ImageAlongPath*** *and* ***PointAlongPath*** *used the same path for transformations.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PointAlongPath.

See Also

- ImageAlongPath – Creates an image from pixels traversed along a path.
- PathAlongPath – Transforms a path to a coordinate system in which the 'axis' path is vertical or horizontal.
- PointAlongArc – Transforms a point to a coordinate system in which the 'axis' arc is vertical or horizontal.

RescaleArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of an arc and translates its center in relation to a reference point.

Syntax

```
void avl::RescaleArc
(
 const avl::Arc2D& inArc,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Arc2D& outArc
)
```

Parameters

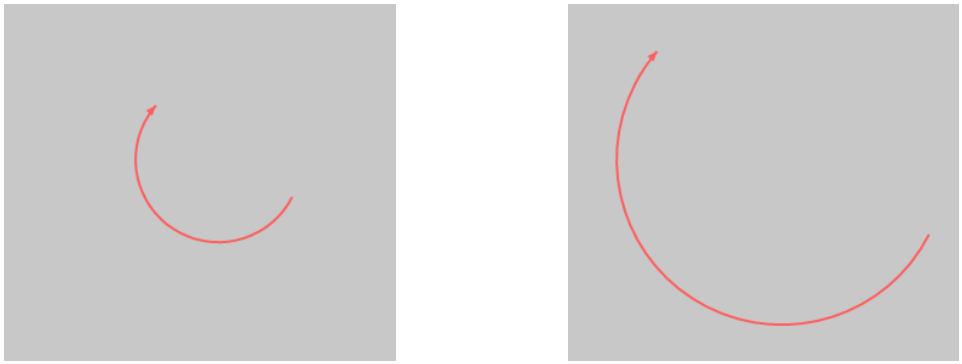
	Name	Type	Default	Description
→	inArc	const Arc2D&		
→	inReferencePoint	Optional<const Point2D&>	NIL	The point to which the distance of the arc center is changed (no change by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Examples



RescaleArc *performed on the sample arc,* ***inReferencePoint*** *= auto,* ***inScale*** *= 2.0 and* ***inInverse*** *= false.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse scaling of an arc in RescaleArc.

RescaleCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of a circle and translates its center in relation to a reference point.

Syntax

```
void avl::RescaleCircle
(
 const avl::Circle2D& inCircle,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Circle2D& outCircle
)
```

Parameters

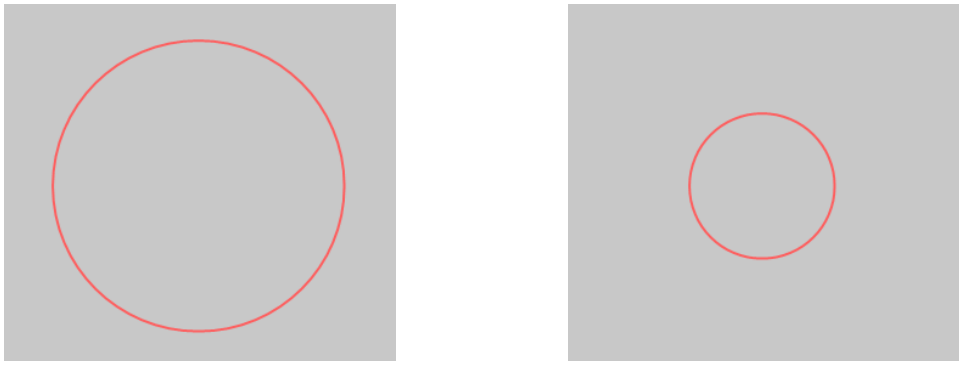
	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inReferencePoint	Optional<const Point2D&>	NIL	The point to which the distance of the circle center is changed (no change by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outCircle	Circle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle** and **outCircle**

Read more about In-place Computation.

Examples



__RescaleCircle__ performed on the sample circle, __inReferencePoint__ = auto, __inScale__ = 0.5 and __inInverse__ = false.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a circle in RescaleCircle.

RescaleLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the distance of a line to a reference point.

Syntax

```
void avl::RescaleLine
(
 const avl::Line2D& inLine,
 const avl::Point2D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Line2D& outLine
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inReferencePoint	const Point2D&		The point to which all distances change linearly
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outLine	Line2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine** and **outLine**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in RescaleLine.
DomainError	Scale cannot be zero in an inverse rescaling of a line in RescaleLine.

RescalePoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the distance of a point to a reference point.

Syntax

```
void avl::RescalePoint
(
 const avl::Point2D& inPoint,
 const avl::Point2D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inReferencePoint	const Point2D&		Point to which the distance will be changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPoint	Point2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint** and **outPoint**

Read more about In-place Computation.

Examples

RescalePoint *performed on the sample point,* ***inReferencePoint*** *= (150.0, 150.0),* ***inScale*** *= -1.5 and* ***inInverse*** *= false. The* ***inReferencePoint*** *point is drawn on the first image in blue.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a point in RescalePoint.

RescalePointArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the distances of points from an array to a reference point.

Syntax

```
void avl::RescalePointArray
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inReferencePoint	Optional<const Point2D&>	NIL	Point to which the distances will be changed (the mass center by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPoints	Array<Point2D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints** and **outPoints**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a point in RescalePointArray.

RescaleRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the corners and the dimensions of a rectangle.

Syntax

```
void avl::RescaleRectangle
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Rectangle2D& outRectangle
)
```

Parameters

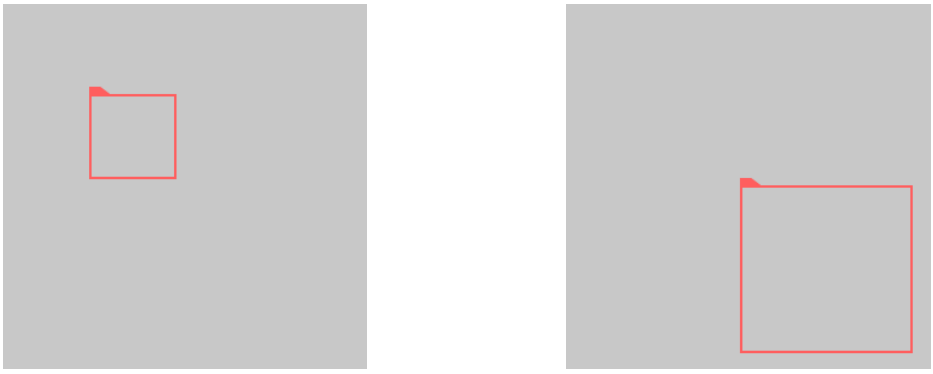
	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inReferencePoint	Optional<const Point2D&>	NIL	The point, to which all distance will be changed proportionally
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Examples



RescaleRectangle *performed on the sample rectangle,* ***inReferencePoint*** *= (0.0, 0.0),* ***inScale*** *= 2.0 and* ***inInverse*** *= false.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in inverse scaling of rectangle in RescaleRectangle.

Also in AVL Lite

RescaleSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Lengthens or shortens a segment relatively.

Syntax

```
void avl::RescaleSegment
(
 const avl::Segment2D& inSegment,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Segment2D& outSegment
)
```

Parameters

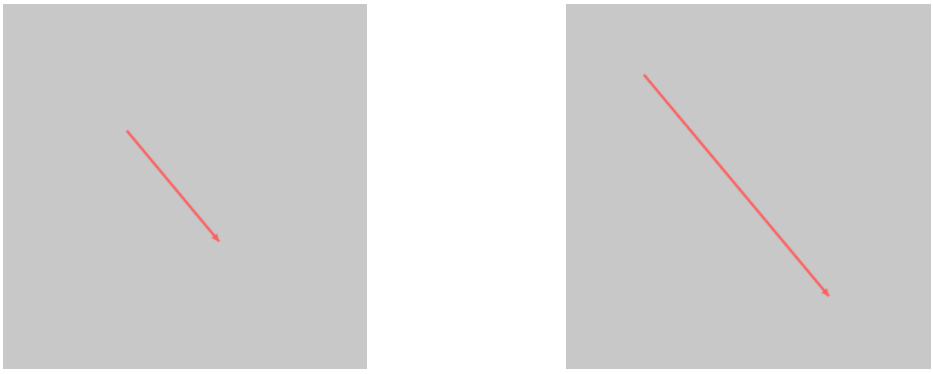
	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inReferencePoint	Optional<const Point2D&>	NIL	The point to which all distances change linearly (the mass center by default)
→	inScale	float	1.0f	Scaling factor (negative values invert the segment)
→	inInverse	bool		Switches to the inverse operation
←	outSegment	Segment2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Examples



RescaleSegment *performed on the sample segment,* ***inReferencePoint*** *= auto,* ***inScale*** *= 2.0 and* ***inInverse*** *= false.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a segment in RescaleSegment.

Also in AVL Lite

RescaleVector

Header: AVL.h
Namespace: avl
Module: FoundationLite

Lengthens or shortens a vector relatively preserving its direction.

Syntax

```
void avl::RescaleVector
(
 const avl::Vector2D& inVector,
 float inScale,
 bool inInverse,
 avl::Vector2D& outVector
)
```

Parameters

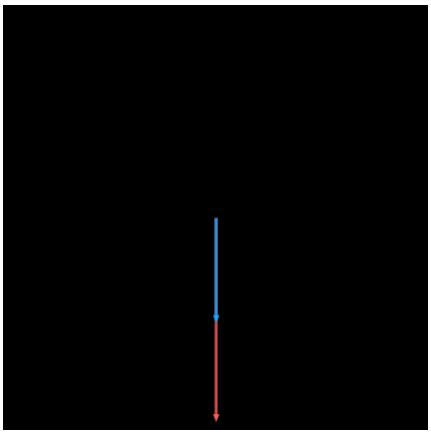
	Name	Type	Default	Description
→	inVector	const Vector2D&		
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outVector	Vector2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inVector** and **outVector**

Read more about In-place Computation.

Examples



RescaleVector *performed on a vector (red one) with* ***DeltaX*** *= 0,* ***DeltaY*** *= 10 with parameters* ***inScale*** *= 5,* ***inInverse*** *= True.* ***outVector*** *returns vector (blue one)*

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse scaling of vector in RescaleVector.

ResizeArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of an arc.

Syntax

```
void avl::ResizeArc
(
 const avl::Arc2D& inArc,
 const float inNewSize,
 avl::Arc2D& outArc
)
```

Parameters

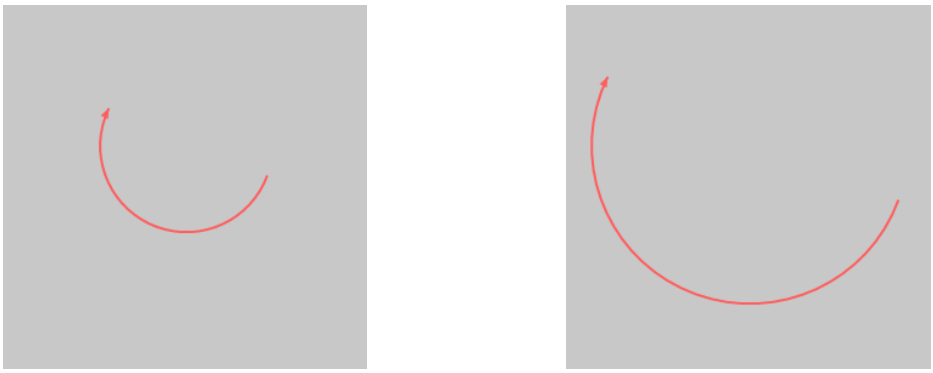
	Name	Type	Range	Default	Description
→	inArc	const Arc2D&			
→	inNewSize	const float	0.0 – ∞	1.0f	
←	outArc	Arc2D&			

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Examples



ResizeArc *performed on the sample arc,* ***inNewSize*** *= 130.*

ResizeArc_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of an arc by adding a value.

Syntax

```
void avl::ResizeArc_Delta
(
 const avl::Arc2D& inArc,
 const float inDelta,
 avl::Arc2D& outArc
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		
→	inDelta	const float	0.0f	Value added to arc radius
←	outArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative arc radius in ResizeArc_Delta.

ResizeCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of a circle.

Syntax

```
void avl::ResizeCircle
(
 const avl::Circle2D& inCircle,
 float inNewSize,
 avl::Circle2D& outCircle
)
```

Parameters

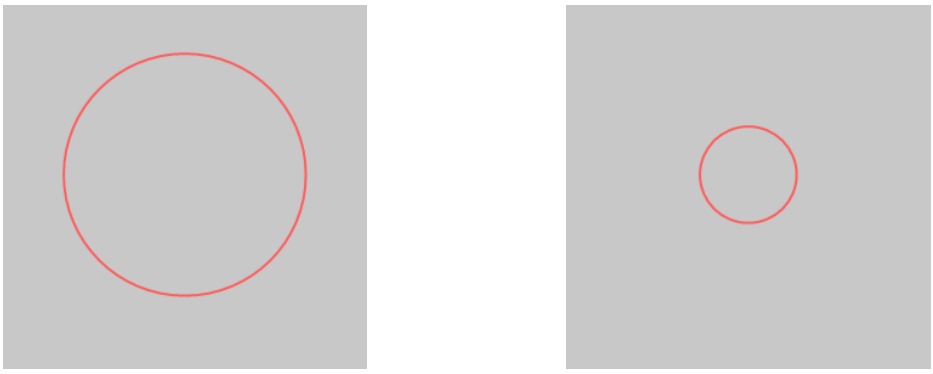
	Name	Type	Range	Default	Description
→	inCircle	const Circle2D&			
→	inNewSize	float	0.0 – ∞	1.0f	New value for radius
←	outCircle	Circle2D&			

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inCircle** and **outCircle**

Read more about In-place Computation.

Examples



ResizeCircle *performed on the sample circle,* ***inNewSize*** *= 40.*

ResizeCircle_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes radius of a circle by adding a value.

Syntax

```
void avl::ResizeCircle_Delta
(
 const avl::Circle2D& inCircle,
 float inDelta,
 avl::Circle2D& outCircle
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inDelta	float	0.0f	Value added to circle radius
←	outCircle	Circle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle** and **outCircle**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative circle radius in ResizeCircle_Delta.

ResizeRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes dimensions of a rectangle.

Syntax

```
void avl::ResizeRectangle
(
 const avl::Rectangle2D& inRectangle,
 avl::Anchor2D::Type inAnchor,
 atl::Optional<float> inNewWidth,
 atl::Optional<float> inNewHeight,
 avl::Rectangle2D& outRectangle
)
```

Parameters

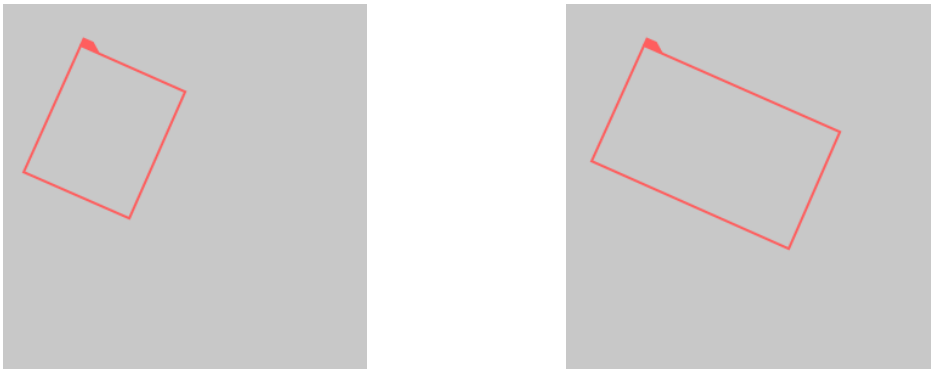
	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			
→	inAnchor	Anchor2D::Type		TopLeft	
→	inNewWidth	Optional<float>	0.0 – ∞	NIL	
→	inNewHeight	Optional<float>	0.0 – ∞	NIL	
←	outRectangle	Rectangle2D&			

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Examples



ResizeRectangle *performed on the sample rectangle,* ***inNewWidth*** *= 177.0 and* ***inNewHeight*** *= 104.0.*

ResizeRectangle_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes dimensions of a rectangle by adding some values.

Syntax

```
void avl::ResizeRectangle_Delta
(
 const avl::Rectangle2D& inRectangle,
 avl::Anchor2D::Type inAnchor,
 float inWidthDelta,
 float inHeightDelta,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inAnchor	Anchor2D::Type	TopLeft	
→	inWidthDelta	float	0.0f	Value added to width of the rectangle
→	inHeightDelta	float	0.0f	Value added to height of the rectangle
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative rectangle dimensions in ResizeRectangle_Delta.

ResizeRectangle_Relative

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes dimensions of a rectangle relatively.

Syntax

```
void avl::ResizeRectangle_Relative
(
 const avl::Rectangle2D& inRectangle,
 avl::Anchor2D::Type inAnchor,
 float inWidthScale,
 float inHeightScale,
 avl::Rectangle2D& outRectangle
)
```

Parameters

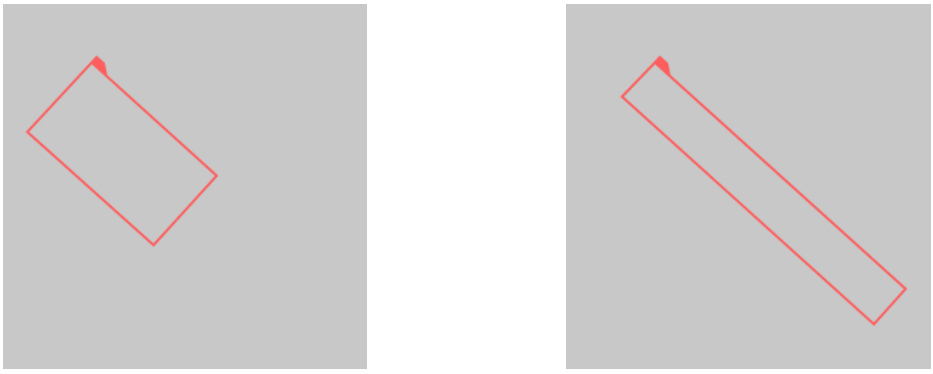
	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			
→	inAnchor	Anchor2D::Type		TopLeft	
→	inWidthScale	float	0.0 – ∞	1.0f	
→	inHeightScale	float	0.0 – ∞	1.0f	
←	outRectangle	Rectangle2D&			

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Examples



ResizeRectangle_Relative *performed on the sample rectangle,* ***inWidthScale*** *= 2.0 and* ***inHeightScale*** *= 0.5.*

Also in AVL Lite

ResizeSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Lengthens or shortens a segment to a new length preserving its orientation and center point.

Syntax

```
void avl::ResizeSegment
(
 const avl::Segment2D& inSegment,
 float inNewLength,
 float inAnchor,
 avl::Segment2D& outSegment
)
```

Parameters

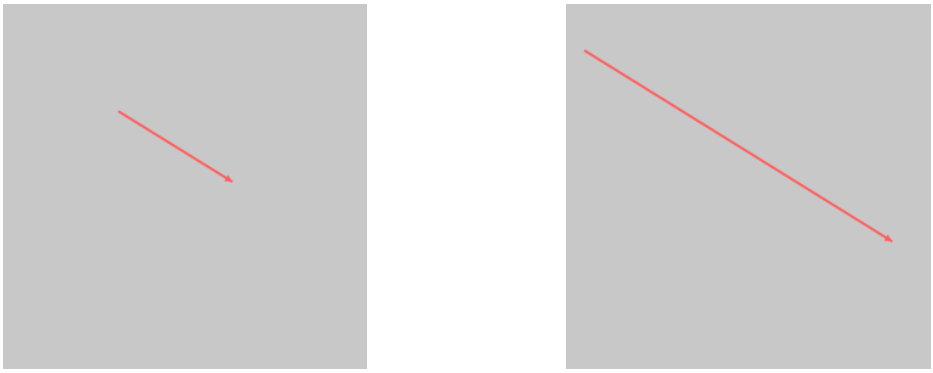
	Name	Type	Range	Default	Description
→	inSegment	const Segment2D&			
→	inNewLength	float	0.0 – ∞	1.0f	
→	inAnchor	float	– ∞ – ∞	0.5f	
←	outSegment	Segment2D&			

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Examples



ResizeSegment *performed on the sample segment,* ***inNewLength*** *= 298.0.*

Also in AVL Lite

ResizeSegment_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes length of a segment by adding a value preserving its orientation and center point.

Syntax

```
void avl::ResizeSegment_Delta
(
 const avl::Segment2D& inSegment,
 float inDelta,
 float inAnchor,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment	const Segment2D&			
→	inDelta	float		0.0f	Value added to segment length
→	inAnchor	float	−∞ … −∞	0.5f	
←	outSegment	Segment2D&			

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative segment length in ResizeSegment_Delta.

ResizeVector

Header: AVL.h
Namespace: avl
Module: FoundationLite

Lengthens or shortens a vector preserving its direction.

Syntax

```
void avl::ResizeVector
(
 const avl::Vector2D& inVector,
 float inNewLength,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVector	const Vector2D&			
→	inNewLength	float	0.0 – ∞	1.0f	
←	outVector	Vector2D&			

In-place Processing

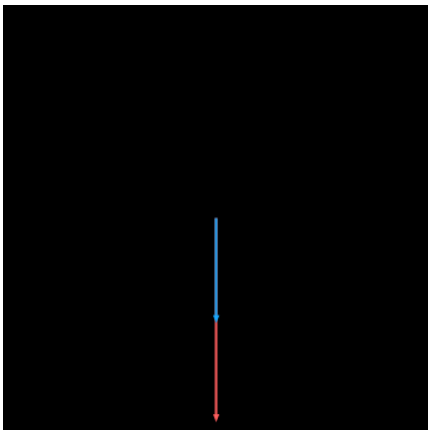
This function supports in-place data processing – you can pass the same reference to **inVector** and **outVector**

Read more about In-place Computation.

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when a zero vector is given on input.

Examples



__ResizeVector__ performed on a vector (red one) with __DeltaX__ = 0, __DeltaY__ = 10 with parameter __inNewLength__ = 5. __outVector__ returns vector (blue one)

ResizeVector_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Extends length of a vector by adding a value preserving its direction.

Syntax

```
void avl::ResizeVector_Delta
(
 const avl::Vector2D& inVector,
 float inDelta,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Default	Description
→	inVector	const Vector2D&		
→	inDelta	float	0.0f	Value added to vector length
←	outVector	Vector2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inVector** and **outVector**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative vector length in ResizeVector_Delta.

ReverseArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Inverts the direction of the arc.

Syntax

```
void avl::ReverseArc
(
 const avl::Arc2D& inArc,
 avl::Arc2D& outArc
)
```

Parameters

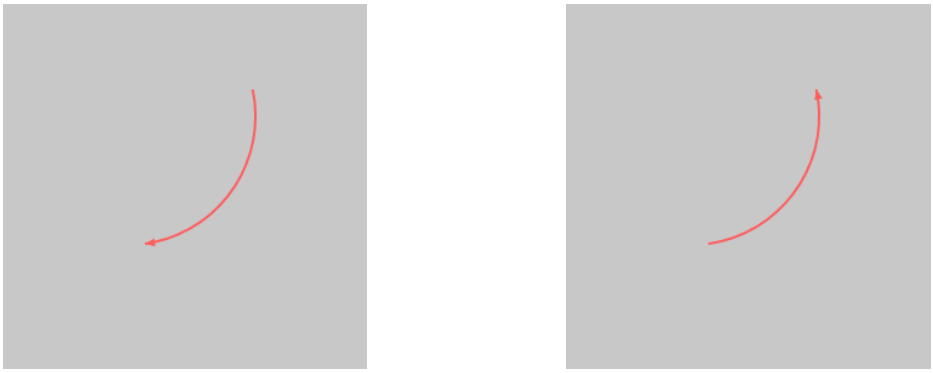
	Name	Type	Default	Description
→	inArc	const Arc2D&		
←	outArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Examples



ReverseArc *performed on the sample arc.*

ReverseSegment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Swaps the two endpoints of a segment.

Syntax

```
void avl::ReverseSegment
(
 const avl::Segment2D& inSegment,
 avl::Segment2D& outSegment
)
```

Parameters

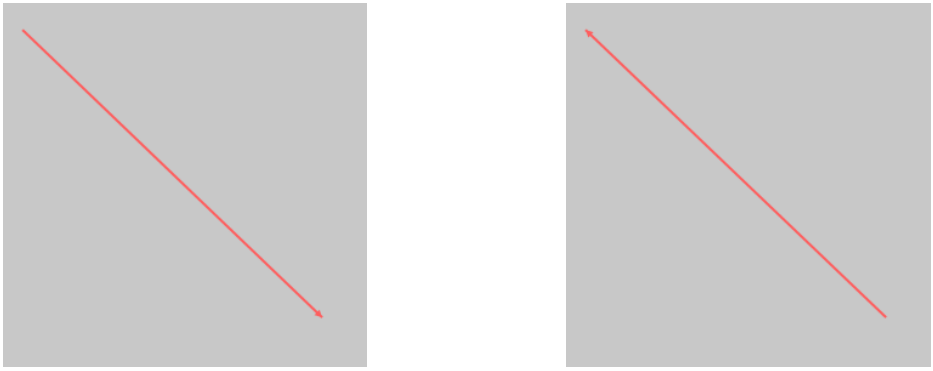
	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outSegment	Segment2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Examples



ReverseSegment *performed on the sample segment.*

RotateAngle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds two angles.

Syntax

```
void avl::RotateAngle
(
 float inAngle,
 float inRotationAngle,
 avl::AngleRange::Type inAngleRange,
 bool inInverse,
 float& outAngle
)
```

Parameters

	Name	Type	Default	Description
→	inAngle	float		
→	inRotationAngle	float		
→	inAngleRange	AngleRange::Type	_0_180	
→	inInverse	bool		
←	outAngle	float&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inAngle** and **outAngle**

Read more about In-place Computation.

RotateAngle_Toward

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the input direction in the direction of minimum rotation toward the target direction.

Syntax

```
void avl::RotateAngle_Toward
(
 float inAngle,
 float inTargetAngle,
 avl::AngleRange::Type inAngleRange,
 float inRotationAngle,
 bool inInverse,
 float& outAngle
)
```

Parameters

	Name	Type	Default	Description
→	inAngle	float		
→	inTargetAngle	float		
→	inAngleRange	AngleRange::Type	_0_180	
→	inRotationAngle	float		
→	inInverse	bool		
←	outAngle	float&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inAngle** and **outAngle**

Read more about In-place Computation.

RotateArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates an arc clockwise around center point.

Syntax

```
void avl::RotateArc
(
 const avl::Arc2D& inArc,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 avl::Arc2D& outArc
)
```

Parameters

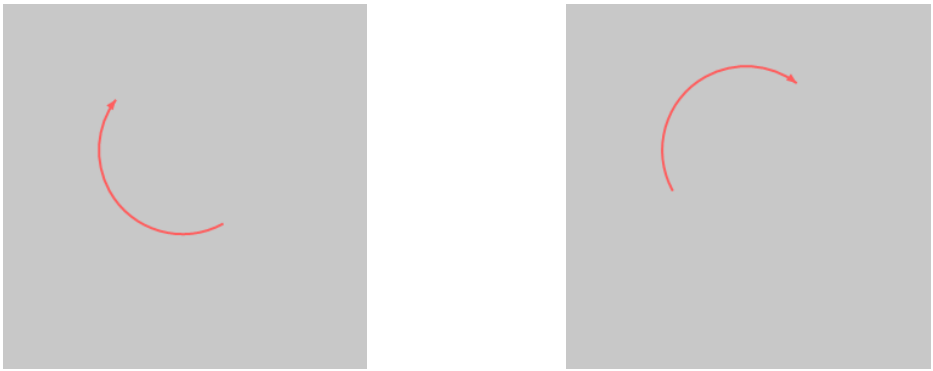
	Name	Type	Default	Description
→	inArc	const Arc2D&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the arc's center by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Examples



__RotateArc__ performed on the sample arc, __inCenter__ = Auto, __inAngle__ = 90 and __inInverse__ = False.

RotateCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a circle clockwise around a center point.

Syntax

```
void avl::RotateCircle
(
 const avl::Circle2D& inCircle,
 const avl::Point2D& inCenter,
 float inAngle,
 bool inInverse,
 avl::Circle2D& outCircle
)
```

Parameters

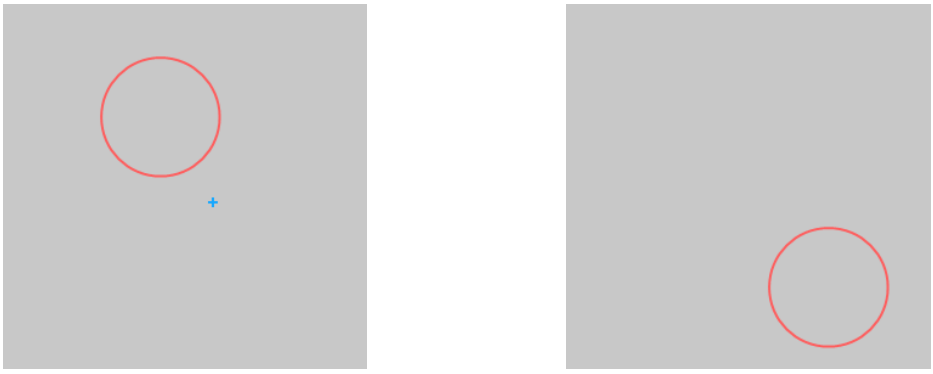
	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inCenter	const Point2D&		Center of rotation
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outCircle	Circle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle** and **outCircle**

Read more about In-place Computation.

Examples



__RotateCircle__ performed on the sample circle, __inCenter__ = (173.0, 163.0), __inAngle__ = 180.0 and __inInverse__ = False. The __inCenter__ point is drawn on the first image in blue

RotateCoordinateSystem

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a coordinate system around a center point.

Syntax

```
void avl::RotateCoordinateSystem
(
 const avl::CoordinateSystem2D& inCoordinateSystem,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inCoordinateSystem	const CoordinateSystem2D&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the coordinate system's center by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outCoordinateSystem	CoordinateSystem2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCoordinateSystem** and **outCoordinateSystem**

Read more about In-place Computation.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

RotateLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a line clockwise around a center point.

Syntax

```
void avl::RotateLine
(
 const avl::Line2D& inLine,
 const avl::Point2D& inCenter,
 float inAngle,
 bool inInverse,
 avl::Line2D& outLine
)
```

Parameters

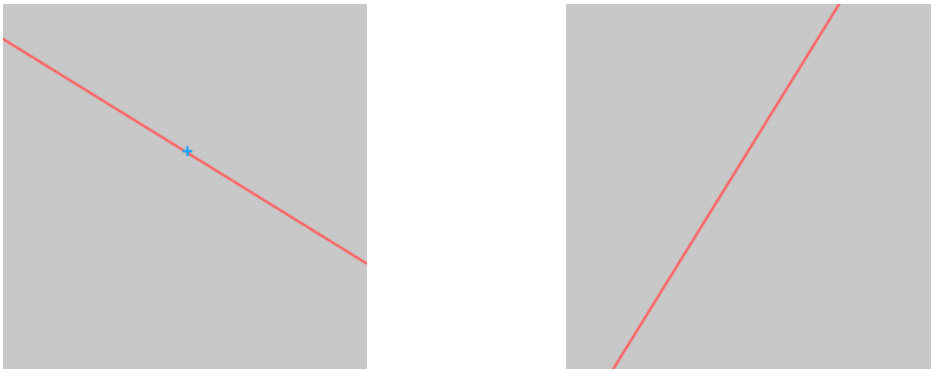
	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inCenter	const Point2D&		Center of rotation
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outLine	Line2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine** and **outLine**

Read more about In-place Computation.

Examples



RotateLine *performed on the sample line,* ***inCenter*** *= (152.0, 121.0),* ***inAngle*** *= 90.0 and* ***inInverse*** *= False. The* ***inCenter*** *point is drawn on the first image in blue.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in RotateLine.

RotatePoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a point clockwise around a center point.

Syntax

```
void avl::RotatePoint
(
 const avl::Point2D& inPoint,
 const avl::Point2D& inCenter,
 float inAngle,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

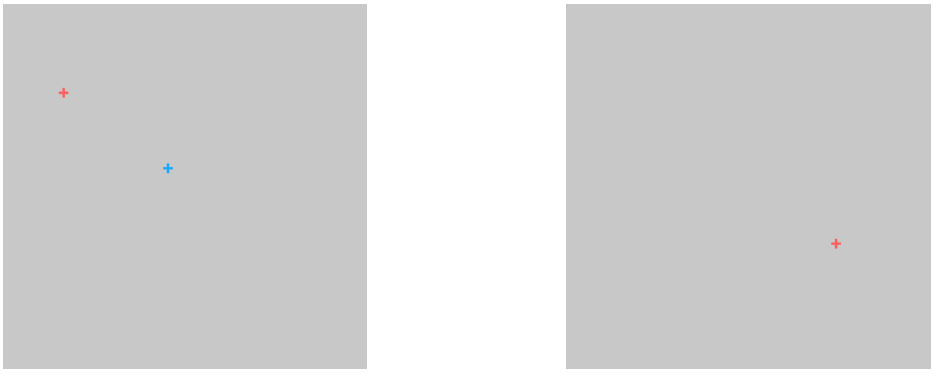
	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inCenter	const Point2D&		Center of rotation
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outPoint	Point2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint** and **outPoint**, **inCenter** and **outPoint**

Read more about In-place Computation.

Examples



RotatePoint *performed on the sample point,* ***inCenter*** *= (136.0, 135.0),* ***inAngle*** *= 180.0 and* ***inInverse*** *= False. The* ***inCenter*** *point is drawn on the first image in blue.*

RotatePointArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates an array of points clockwise around a center point.

Syntax

```
void avl::RotatePointArray
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the mass center by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outPoints	Array<Point2D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints** and **outPoints**

Read more about In-place Computation.

RotateRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a rectangle clockwise around a center point.

Syntax

```
void avl::RotateRectangle
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 avl::Rectangle2D& outRectangle
)
```

Parameters

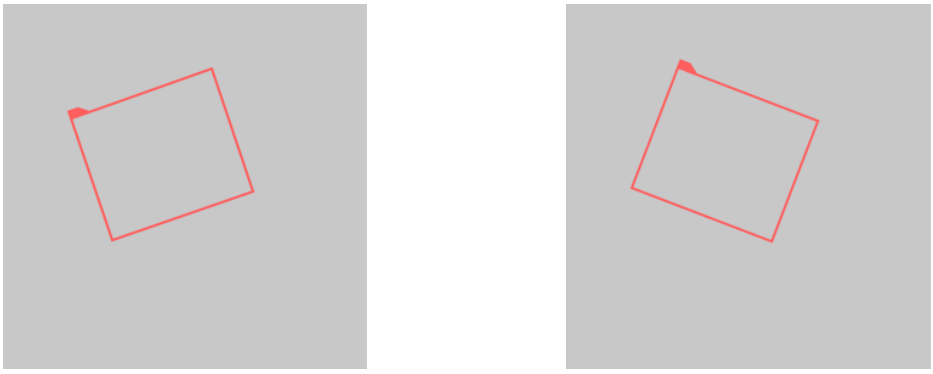
	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the rectangle's point by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Examples



RotateRectangle *performed on the sample rectangle,* ***inCenter*** *= Auto,* ***inAngle*** *= 40.0 and* ***inInverse*** *= False.*

RotateSegment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a segment clockwise around a center point.

Syntax

```
void avl::RotateSegment
(
 const avl::Segment2D& inSegment,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 avl::Segment2D& outSegment
)
```

Parameters

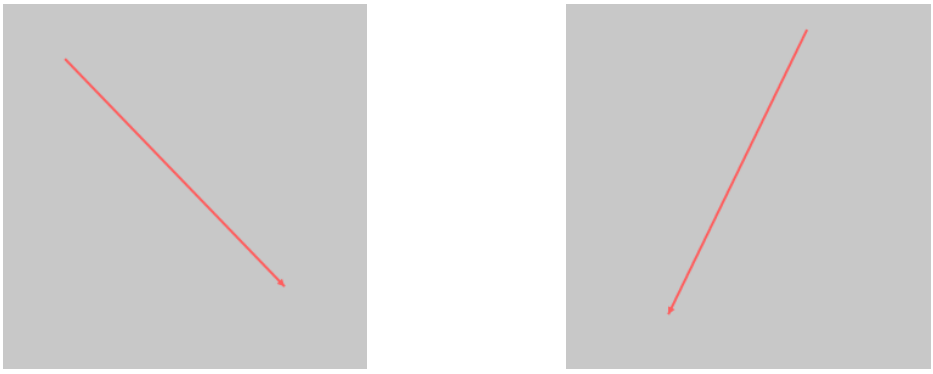
	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (by default the mass center)
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outSegment	Segment2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Examples



RotateSegment *performed on the sample segment,* ***inCenter*** *= Auto,* ***inAngle*** *= 70.0 and* ***inInverse*** *= False.*

RotateVector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a vector clockwise.

Syntax

```
void avl::RotateVector
(
 const avl::Vector2D& inVector,
 float inAngle,
 bool inInverse,
 avl::Vector2D& outVector
)
```

Parameters

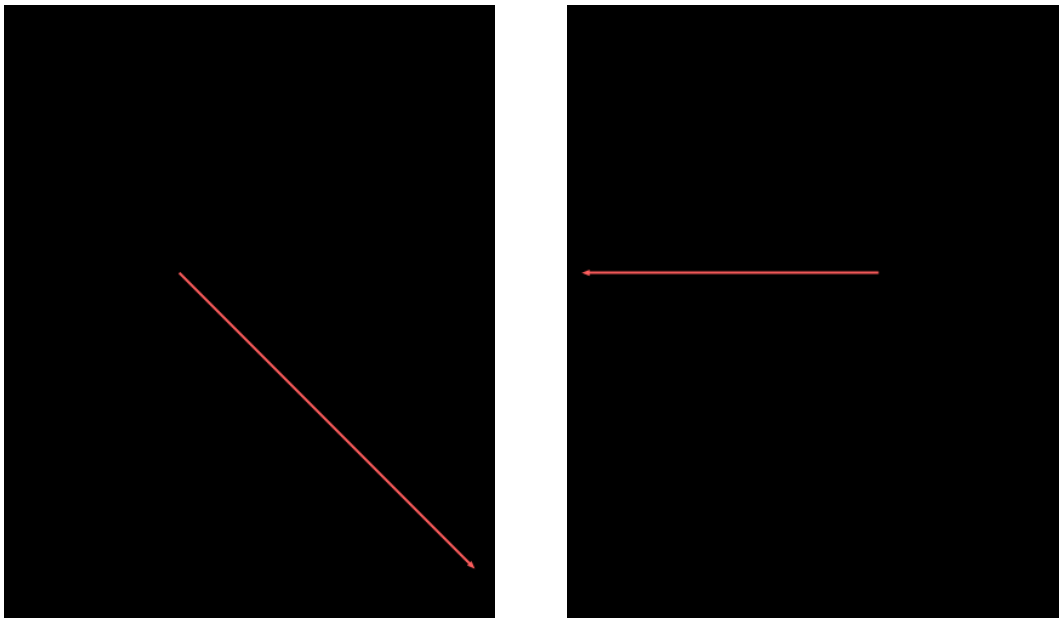
	Name	Type	Default	Description
→	inVector	const Vector2D&		
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outVector	Vector2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inVector** and **outVector**

Read more about In-place Computation.

Examples



__RotateVector__ performed on the sample vector, __inAngle__ = 135.0 and __inInverse__ = False.

SplitPointsByLine

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Separates the points being on one side of the input line from the others.

Syntax

```
void avl::SplitPointsByLine
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Line2D& inLine,
 atl::Array<avl::Point2D>& outPoints1,
 atl::Array<avl::Point2D>& outPoints2
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input points
→	inLine	const Line2D&		Line used for splitting
←	outPoints1	Array<Point2D>&		Points with positive signed distance to the input line
←	outPoints2	Array<Point2D>&		Points with negative signed distance to the input line

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in SplitPointsByLine.

SplitSegment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Splits a segment into several parts of equal length.

Syntax

```
void avl::SplitSegment
(
 const avl::Segment2D& inSegment,
 const int inCount,
 atl::Array<avl::Segment2D>& outSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment	const Segment2D&			
→	inCount	const int	1 – ∞	2	Number of segments after segment split
←	outSegments	Array<Segment2D>&			

Description

Filter computes **outSegments** using following formulas:

$$\mathbf{outSegments}[0].x_{begin} = \mathbf{inSegment}.x_{begin}$$

$$\mathbf{outSegments}[0].y_{begin} = \mathbf{inSegment}.y_{begin}$$

$$\mathbf{outSegments}[0].x_{end} = \mathbf{inSegment}.x_{begin} + \Delta x$$

$$\mathbf{outSegments}[0].y_{end} = \mathbf{inSegment}.y_{begin} + \Delta y$$

$$\mathbf{outSegments}[i].x_{begin} = \mathbf{outSegments}[i-1].x_{begin} + \Delta x$$

$$\mathbf{outSegments}[i].y_{begin} = \mathbf{outSegments}[i-1].y_{begin} + \Delta y$$

$$\mathbf{outSegments}[i].x_{end} = \mathbf{outSegments}[i-1].x_{end} + \Delta x$$

$$\mathbf{outSegments}[i].y_{end} = \mathbf{outSegments}[i-1].y_{end} + \Delta y$$

$$i = 1, 2, .., \mathbf{inCount} - 1$$

where

$$\Delta x = \frac{\mathbf{inSegment}.x_{end} - \mathbf{inSegment}.x_{begin}}{\mathbf{inCount}}$$

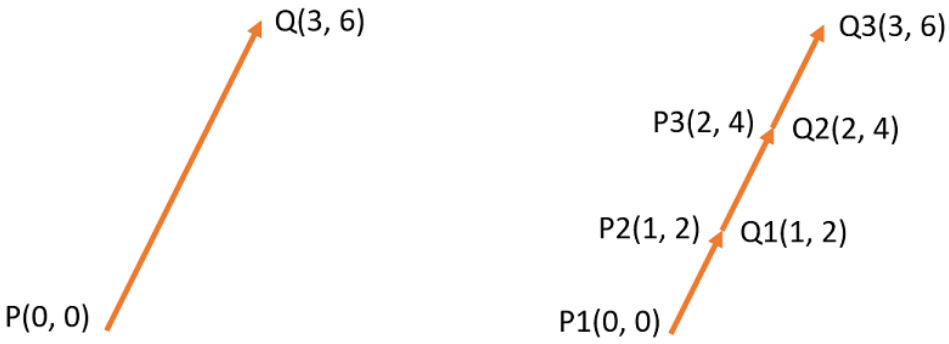
$$\Delta y = \frac{\mathbf{inSegment}.y_{end} - \mathbf{inSegment}.y_{begin}}{\mathbf{inCount}}$$

Examples

Assume segment described with two points:

- Start point P(0, 0)
- End point Q(3, 6).

To split segment into three parts of equal length, set **inCount** = 3.
Result will be as follows:



$$\mathbf{outSegments}[0] = \vec{P_1Q_1} = [1, 2] \quad \mathbf{outSegments}[1] = \vec{P_2Q_2} = [1, 2] \quad \mathbf{outSegments}[2] = \vec{P_3Q_3} = [1, 2]$$

TranslateArc

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates an arc by a vector.

Syntax

```
void avl::TranslateArc
(
 const avl::Arc2D& inArc,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::Arc2D& outArc
)
```

Parameters

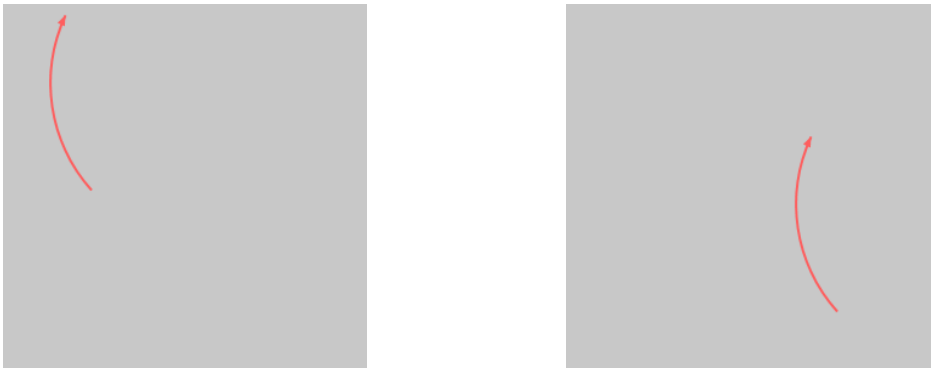
	Name	Type	Default	Description
→	inArc	const Arc2D&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outArc	Arc2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inArc** and **outArc**

Read more about In-place Computation.

Examples



TranslateArc *performed on the sample arc,* ***inDelta*** *= (150.0, 100.0) and* ***inInverse*** *= False.*

TranslateCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a circle by a vector.

Syntax

```
void avl::TranslateCircle
(
 const avl::Circle2D& inCircle,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::Circle2D& outCircle
)
```

Parameters

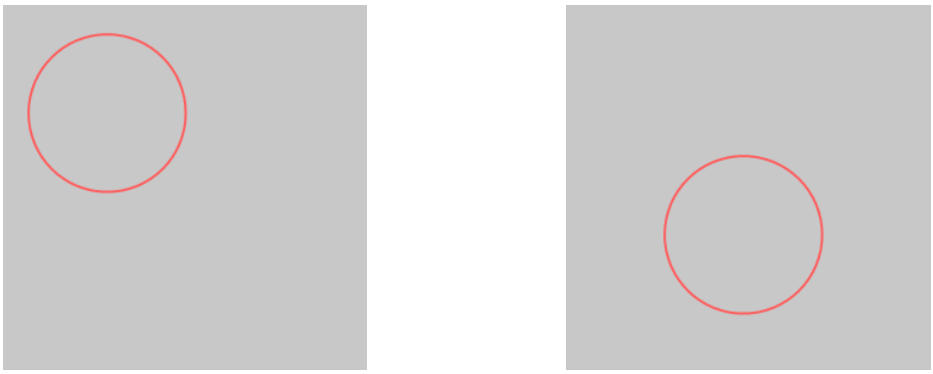
	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inDelta	const Vector2D&		Vector of translation
→	inInverse	bool		Switches to the inverse operation
←	outCircle	Circle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle** and **outCircle**

Read more about In-place Computation.

Examples



__TranslateCircle__ performed on the sample circle, __inDelta__ = (60.0, 100.0) and __inInverse__ = False.

TranslateCoordinateSystem

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a coordinate system by a vector.

Syntax

```
void avl::TranslateCoordinateSystem
(
 const avl::CoordinateSystem2D& inCoordinateSystem,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inCoordinateSystem	const CoordinateSystem2D&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outCoordinateSystem	CoordinateSystem2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCoordinateSystem** and **outCoordinateSystem**

Read more about In-place Computation.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

TranslateLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a line by a vector.

Syntax

```
void avl::TranslateLine
(
 const avl::Line2D& inLine,
 const avl::Vector2D& inDelta,
 bool inInverse,
 const avl::TranslateAlignment::Type inDeltaAlignment,
 avl::Line2D& outLine
)
```

Parameters

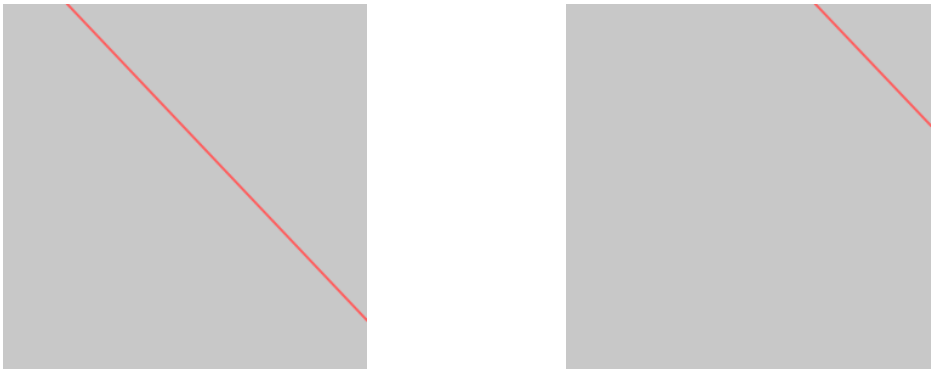
	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inDelta	const Vector2D&		Vector of translation
→	inInverse	bool		Switches to the inverse operation
→	inDeltaAlignment	const TranslateAlignment::Type		
←	outLine	Line2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine** and **outLine**

Read more about In-place Computation.

Examples



TranslateLine *performed on the sample line,* ***inDelta*** *= (200.0, 50.0) and* ***inInverse*** *= False.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in TranslateLine.

TranslatePoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a point by a vector.

Syntax

```
void avl::TranslatePoint
(
 const avl::Point2D& inPoint,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

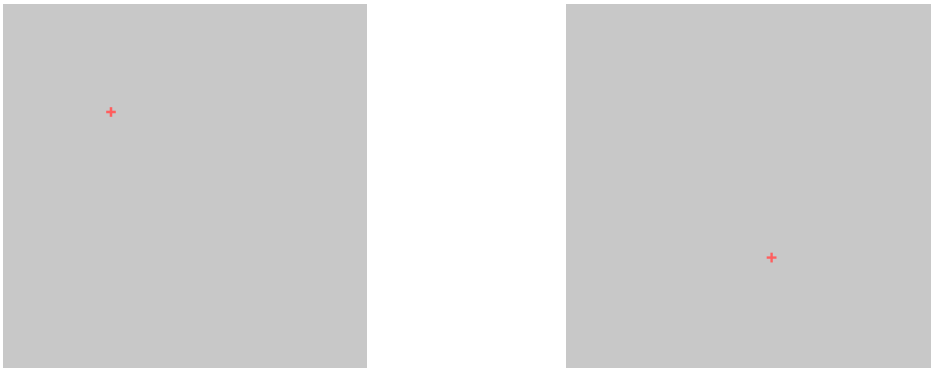
	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPoint	Point2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint** and **outPoint**

Read more about In-place Computation.

Examples



__TranslatePoint__ performed on the sample point, __inDelta__ = (80.0, 120.0) and __inInverse__ = False.

TranslatePointArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates an array of points by a vector.

Syntax

```
void avl::TranslatePointArray
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Vector2D& inDelta,
 bool inInverse,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPoints	Array<Point2D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints** and **outPoints**

Read more about In-place Computation.

TranslatePoint_Toward

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a point towards another point by a specified distance.

Syntax

```
void avl::TranslatePoint_Toward
(
 const avl::Point2D& inPoint,
 const avl::Point2D& inTargetPoint,
 float inDistance,
 bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inTargetPoint	const Point2D&		Defines the direction of the translation
→	inDistance	float		The distance between inPoint and outPoint
→	inInverse	bool		Switches to the inverse operation
←	outPoint	Point2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint** and **outPoint**

Read more about In-place Computation.

TranslateRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a rectangle by a vector.

Syntax

```
void avl::TranslateRectangle
(
 const avl::Rectangle2D& inRectangle,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::Rectangle2D& outRectangle
)
```

Parameters

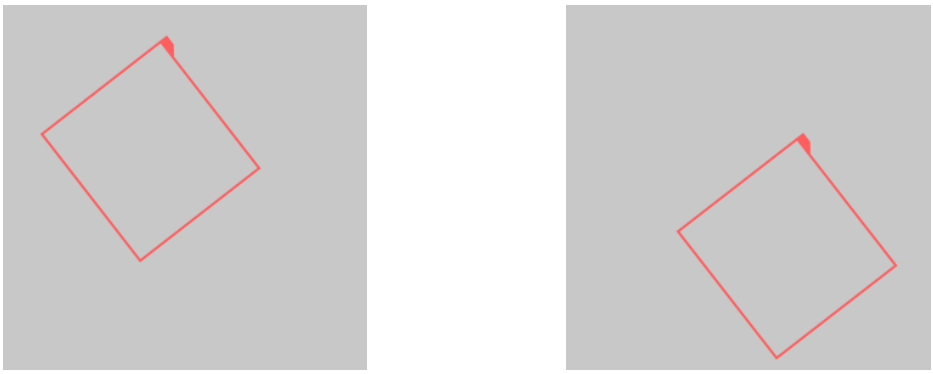
	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Examples



TranslateRectangle *performed on the sample rectangle,* ***inDelta*** *= (60.0, 80.0) and* ***inInverse*** *= False.*

TranslateSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a segment by a vector.

Syntax

```
void avl::TranslateSegment
(
 const avl::Segment2D& inSegment,
 const avl::Vector2D& inDelta,
 bool inInverse,
 const avl::TranslateAlignment::Type inDeltaAlignment,
 avl::Segment2D& outSegment
)
```

Parameters

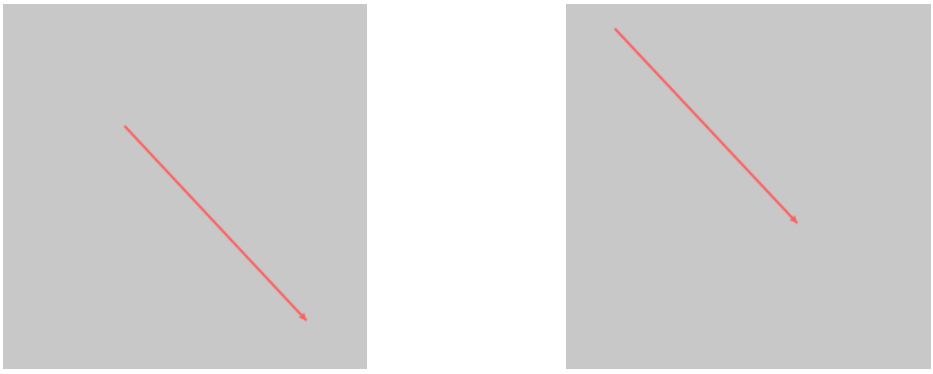
	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
→	inDeltaAlignment	const TranslateAlignment::Type		
←	outSegment	Segment2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment** and **outSegment**

Read more about In-place Computation.

Examples



TranslateSegment *performed on the sample segment,* ***inDelta*** *= (-60.0, -80.0) and* ***inInverse*** *= False.*

Also in AVL Lite

TrimLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment contained in a box from a line.

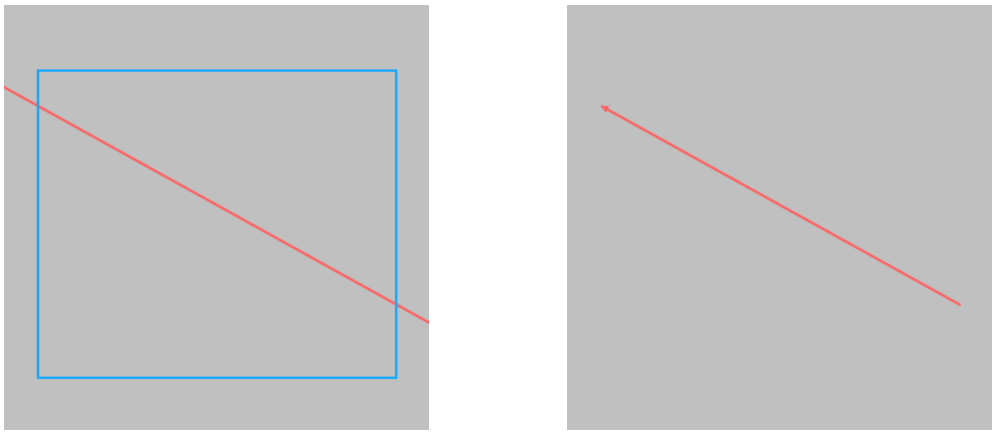
Syntax

```
void avl::TrimLine
(
 const avl::Line2D& inLine,
 const avl::Box& inBox,
 atl::Conditional<avl::Segment2D>& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inBox	const Box&		Box defining a region the input line will be cropped to
←	outSegment	Conditional<Segment2D>&		

Examples



TrimLine performed on line and box.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in TrimLine.

TrimLineToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment contained in a rectangle from a line.

Syntax

```
void avl::TrimLineToRectangle
(
 const avl::Line2D& inLine,
 const avl::Rectangle2D& inRectangle,
 atl::Conditional<avl::Segment2D>& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inRectangle	const Rectangle2D&		Rectangle defining a region the input line will be cropped to
←	outSegment	Conditional<Segment2D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in TrimLineToRectangle.

TrimPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a path contained in a box from another path.

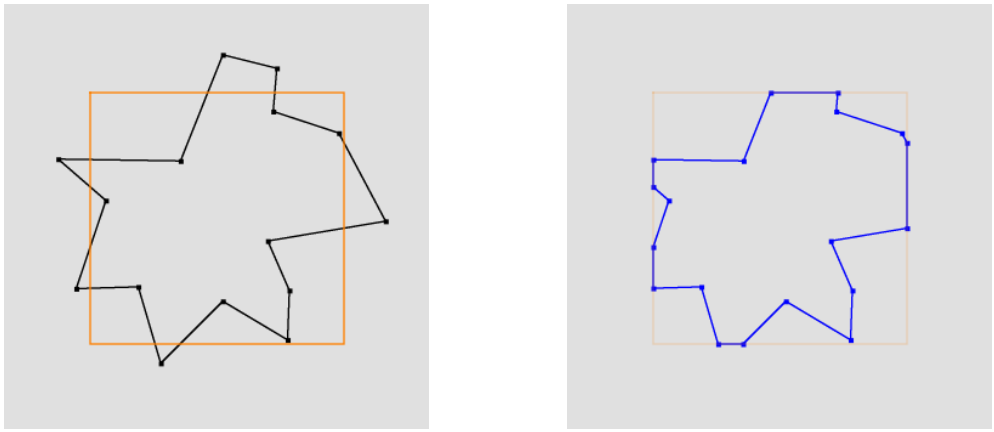
Syntax

```
void avl::TrimPath
(
 const avl::Path& inPath,
 const avl::Box& inBox,
 avl::TrimPathMethod::Type inTrimPathMethod,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inBox	const Box&		
→	inTrimPathMethod	TrimPathMethod::Type	PointToPoint	
←	outPath	Path&		Output path

Examples



TrimPath *performed on the sample box and path.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown method for cropping a path in TrimPath.

Also in AVL Lite

TrimPathArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an array of paths contained in a box from another array of paths.

Syntax

```
void avl::TrimPathArray
(
 const atl::Array<avl::Path>& inPaths,
 const avl::Box& inBox,
 avl::TrimPathMethod::Type inTrimPathMethod,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inBox	const Box&		
→	inTrimPathMethod	TrimPathMethod::Type	PointToPoint	
←	outPaths	Array<Path>&		

Also in AVL Lite

TrimPathArrayToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an array of paths contained in a rectangle from another array of paths.

Syntax

```
void avl::TrimPathArrayToRectangle
(
 const atl::Array<avl::Path>& inPaths,
 const avl::Rectangle2D& inRectangle,
 avl::TrimPathMethod::Type inTrimPathMethod,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inRectangle	const Rectangle2D&		
→	inTrimPathMethod	TrimPathMethod::Type	PointToPoint	
←	outPaths	Array<Path>&		

Also in AVL Lite

TrimPathToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a path contained in a rectangle from another path.

Syntax

```
void avl::TrimPathToRectangle
(
 const avl::Path& inPath,
 const avl::Rectangle2D& inRectangle,
 avl::TrimPathMethod::Type inTrimPathMethod,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inRectangle	const Rectangle2D&		
→	inTrimPathMethod	TrimPathMethod::Type	PointToPoint	
←	outPath	Path&		Output path

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown method for cropping a path in TrimPathToRectangle.

Also in AVL Lite

TrimPointArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes points not contained in a box from an array.

Syntax

```
void avl::TrimPointArray
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Box& inBox,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inBox	const Box&		
←	outPoints	Array<Point2D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints** and **outPoints**

Read more about In-place Computation.

TrimPointArrayToRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Trims an array of points to a region.

Syntax

```
void avl::TrimPointArrayToRegion
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Region& inRegion,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRegion	const Region&		Input region
←	outPoints	Array<Point2D>&		

TrimSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment contained in a box from another segment.

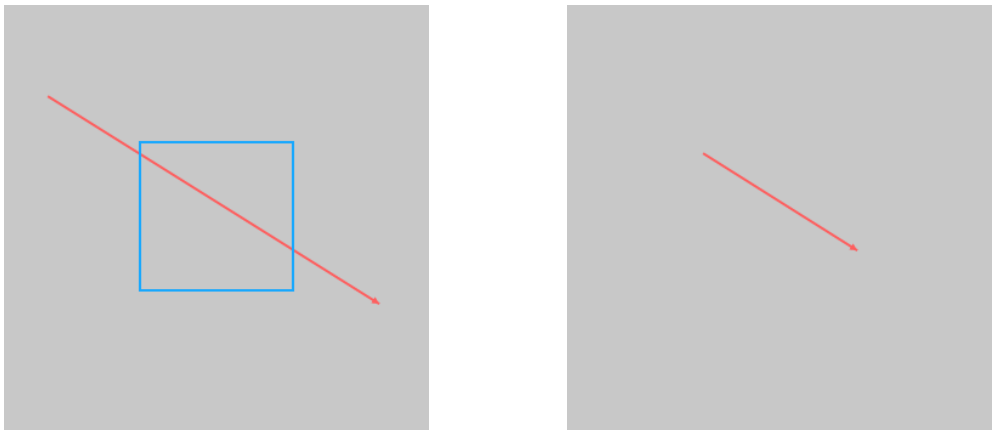
Syntax

```
void avl::TrimSegment
(
 const avl::Segment2D& inSegment,
 const avl::Box& inBox,
 atl::Conditional<avl::Segment2D>& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inBox	const Box&		
←	outSegment	Conditional<Segment2D>&		

Examples



TrimSegment *performed on the sample box and segment.*

TrimSegmentToCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment contained in a circle from another segment.

Syntax

```
void avl::TrimSegmentToCircle
(
 const avl::Segment2D& inSegment,
 const avl::Circle2D& inCircle,
 atl::Conditional<avl::Segment2D>& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inCircle	const Circle2D&		Circle defining a region the input segment will be cropped to
←	outSegment	Conditional<Segment2D>&		

TrimSegmentToPolygon

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds all subsegments that are inside a given polygon.

Syntax

```
void avl::TrimSegmentToPolygon
(
 const avl::Path& inPolygon,
 const avl::Segment2D& inSegment,
 atl::Array<avl::Segment2D>& outSubsegments
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
→	inSegment	const Segment2D&		
←	outSubsegments	Array<Segment2D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in TrimSegmentToPolygon.
DomainError	Open path on input in TrimSegmentToPolygon.

TrimSegmentToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment contained in a rectangle from another segment.

Syntax

```
void avl::TrimSegmentToRectangle
(
 const avl::Segment2D& inSegment,
 const avl::Rectangle2D& inRectangle,
 atl::Conditional<avl::Segment2D>& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inRectangle	const Rectangle2D&		Rectangle defining a region the input segment will be cropped to
←	outSegment	Conditional<Segment2D>&

AlignPath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves a path from a local coordinate system to the absolute one.

Applications: Required when there is a path defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignPath
(
 const avl::Path& inPath,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 avl::Path& outAlignedPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedPath	Path&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outAlignedPath**

Read more about In-place Computation.

Description

AlignPath aligns the **inPath** to the **inAlignment** coordinate system. The input path is translated, rotated and scaled.

The **inAlignment** is usually an alignment of an object found by some template matching algorithm.

Examples

***AlignPath** run on the sample paths.*

See Also

- TranslatePath - Translates a path by a vector.
- RotatePath - Rotates a path clockwise around a center point.

AlignPathArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves an array of paths from a local coordinate system to the absolute one.

Applications: Required when there are paths defined in a local coordinate system, but the next image-related filter in the program does not have any inAlignment input.

Syntax

```
void avl::AlignPathArray
(
 const atl::Array<avl::Path>& inPaths,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 atl::Array<avl::Path>& outAlignedPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inAlignment	const CoordinateSystem2D&		Coordinate system to align to
→	inInverse	bool		Switches to the inverse transform
←	outAlignedPaths	Array<Path>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPaths** and **outAlignedPaths**

Read more about In-place Computation.

FitPathToPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Rotates and shifts a path to minimize average distance between its points and a reference path.

Syntax

```
void avl::FitPathToPath
(
 const avl::Path& inPath,
 const avl::Path& inReferencePath,
 avl::PathOrientationAlignment::Type inPathOrientationAlignment,
 const int inIterations,
 const float inFirstShift,
 const float inFirstRotation,
 avl::Path& outPath,
 avl::CoordinateSystem2D& outAlignment,
 float& outPathDistance
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Path to be aligned
→	inReferencePath	const Path&			Path to align to
→	inPathOrientationAlignment	PathOrientationAlignment::Type		EllipticAxes	Determines how to align paths orientation before the main algorithm
→	inIterations	const int	1 – ∞	5	Number of algorithm steps
→	inFirstShift	const float		10.0f	Magnitude of possible shift at the first step in pixels
→	inFirstRotation	const float		10.0f	Magnitude of possible rotation at the first step in degrees
←	outPath	Path&			Aligned path
←	outAlignment	CoordinateSystem2D&			The coordinate system that geometrical objects defined in the context of the path should be aligned to
←	outPathDistance	float&			Average distance of characteristic points of the input path from the reference path

Description

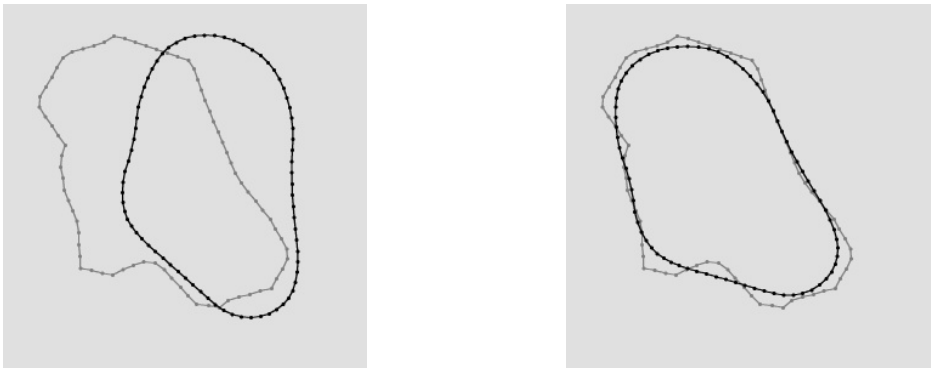
The operations repeatedly performs shifts and rotations on the **inPath** minimizing the average distance between its characteristic points and **inReferencePath**.

Initially the **inPath** is shifted so that its mass center is equals the mass center of **inReferencePath**. Then the alignment is performed in **inIterations** steps. At each step the algorithm considers:

1. Shifts of the processed path in four major directions by **ShiftMagnitude** pixels
2. Rotations of the processed path in clockwise and counter-clockwise direction by **RotationMagnitude** degrees

At each substep the operation performs shift or rotation that produces the best distance minimization results. The initial value of **ShiftMagnitude** is **inFirstShift** and at each step it is divided by 2. Analogically the initial value of **RotationMagnitude** is **inFirstRotation** and at each step it is divided by 2.

Examples



FitPathToPath *run on the sample paths with* ***inIterations*** *= 5,* ***inFirstShift*** *= 10,* ***inFirstRotation*** *= 10. The* ***inReferencePath*** *plotted in grey, the* ***inPath/outPath*** *in black.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in FitPathToPath.

InflatePath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Enlarges a path by a given margin (points in the input path must be sorted clockwise).

Syntax

```
void avl::InflatePath
(
 const avl::Path& inPath,
 float inMargin,
 float inMaxPointDisplacement,
 atl::Conditional<avl::Path>& outPath
)
```

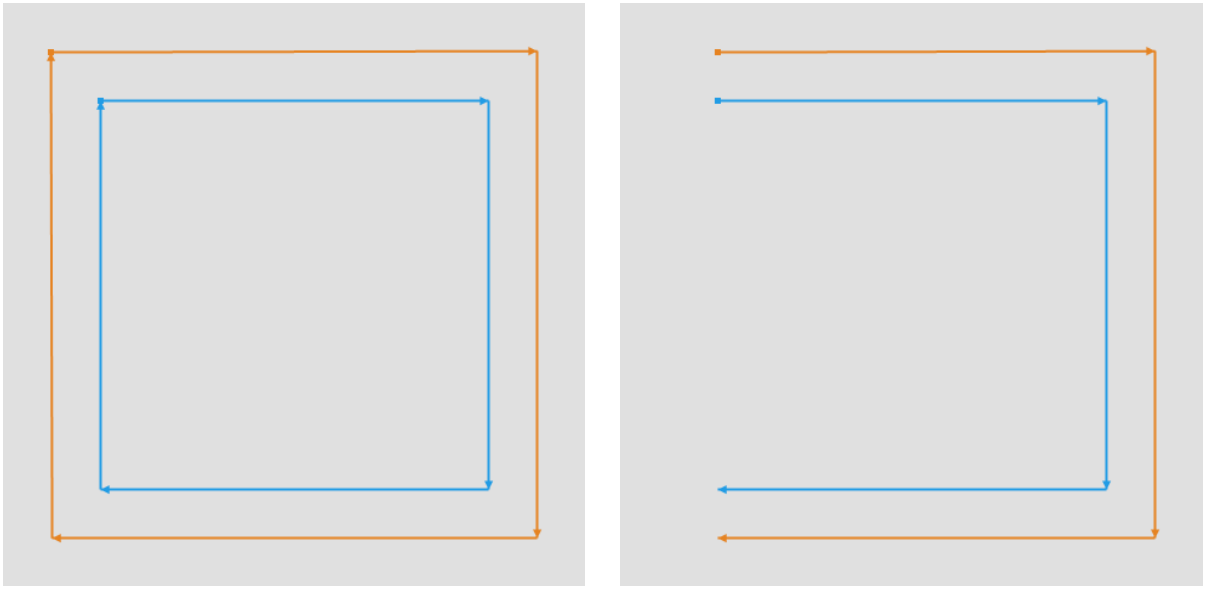
Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inMargin	float			Margin of inflation
→	inMaxPointDisplacement	float	0.0 – ∞	1000.0f	Maximal displacement of single point
←	outPath	Conditional<Path>&			Output path

Description

Creates a new path by enlarging the existing one. Distance between corresponding segments of **inPath** and **outPath** is defined by **inMargin**.

Examples



Example of inflation of initial path (blue). Result is in orange. Note that results for closed (on left) and open path (on right) are slightly different.

PathAlongArc

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Transforms a path to a coordinate system in which the 'axis' arc is vertical or horizontal.

Applications: Usually used to revert an ImageAlongArc transformation.

Syntax

```
void avl::PathAlongArc
(
 const avl::Path& inPath,
 const avl::Arc2D& inAxis,
 avl::Axis::Type inAxisType,
 float inAxisCoordinate,
 bool inInverse,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAxis	const Arc2D&		Input axis arc
→	inAxisType	Axis::Type	Y	Type of axis the input axis arc is parallel to
→	inAxisCoordinate	float	0.0f	Coordinate of the axis arc
→	inInverse	bool	True	Switches to the inverse operation
←	outPath	Path&		Transformed path

In-place Processing

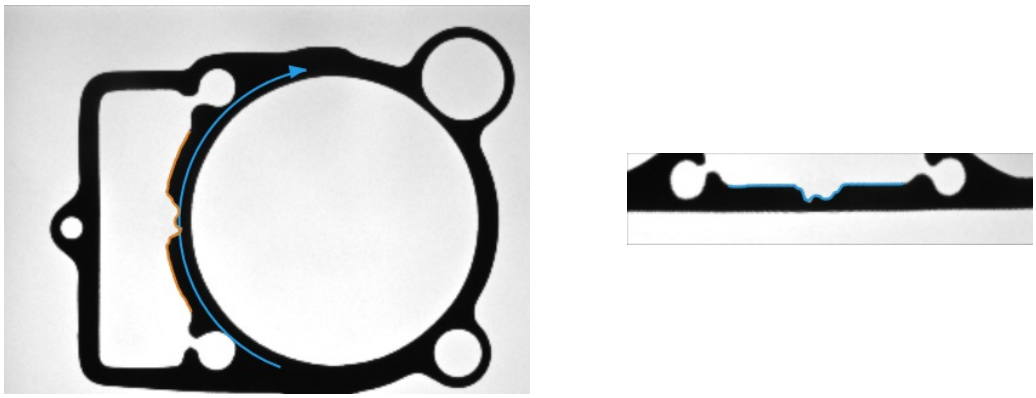
This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

Description

This filter transforms each point in **inPath** the same way how **PointAlongArc** does.

Examples



ImageAlongArc *performed on the sample image with* ***inAxisType*** *= X and* ***inScanWidth*** *= 50. Blue path on output image was reprojected on original image (as orange path) using* ***PathAlongArc*** *with* ***inAxisType*** *= X,* ***inAxisCoordinate*** *= 25,* ***inInverse*** *= true.* ***ImageAlongArc*** *and* ***PathAlongArc*** *used the same arc for transformations.*

Remarks

No new points are being added to input path during transformation, and this may lead to some "distortions" of path. This is especially visible on long, straight portions of input path, which are described with only 2 points: the beginning one and the ending one. After transformation, such part of path is still a line, but it may not be corresponding to the transformed image. Easy way to overcome this problem is to increase number of points creating an transformed path.

See Also

- ImageAlongArc - Creates an image from pixels traversed along an arc.
- PointAlongArc - Transforms a point to a coordinate system in which the 'axis' arc is vertical or horizontal.
- PathAlongPath - Transforms a path to a coordinate system in which the 'axis' path is vertical or horizontal.

PathAlongPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms a path to a coordinate system in which the 'axis' path is vertical or horizontal.

Applications: Usually used to revert an ImageAlongPath transformation.

Syntax

```
void avl::PathAlongPath
(
 const avl::Path& inPath,
 const avl::Path& inAxis,
 avl::Axis::Type inAxisType,
 float inAxisCoordinate,
 bool inInverse,
 avl::Path& outPath
)
```

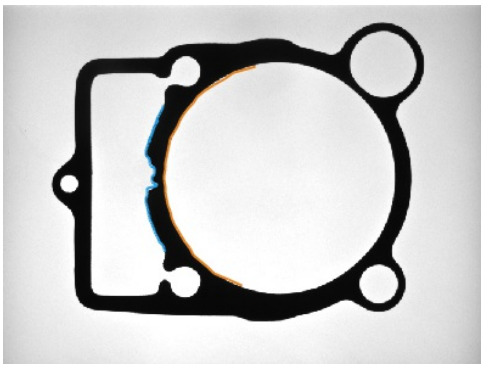
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAxis	const Path&		Input axis path
→	inAxisType	Axis::Type	Y	Type of axis the input axis path is parallel to
→	inAxisCoordinate	float	0.0f	Coordinate of the axis path
→	inInverse	bool	True	Switches to the inverse operation
←	outPath	Path&		Transformed path

Description

This filter transforms each point in **inPath** the same way how **PointAlongPath** does.

Examples



ImageAlongPath *performed on the sample image with* ***inAxisType*** *= X and* ***inScanWidth*** *= 50. Blue path on output image was reprojected on original image using* ***PathAlongPath*** *with* ***inAxisType*** *= X,* ***inAxisCoordinate*** *= 25,* ***inInverse*** *= true.* ***ImageAlongPath*** *and* ***PathAlongPath*** *used the same path (the orange one) for transformations.*

Remarks

No new points are being added to input path during transformation, and this may lead to some "distortions" of path. This is especially visible on long, straight portions of input path, which are described with only 2 points: the beginning one and the ending one. After transformation, such part of path is still a line, but it may not be corresponding to the transformed image. Easy way to overcome this problem is to increase number of points creating an transformed path.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathAlongPath.

See Also

- ImageAlongPath – Creates an image from pixels traversed along a path.
- PointAlongPath – Transforms a point to a coordinate system in which the 'axis' path is vertical or horizontal.
- PathAlongArc – Transforms a path to a coordinate system in which the 'axis' arc is vertical or horizontal.

PathProjectionProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the distance from the line to the path.

Syntax

```
void avl::PathProjectionProfile
(
 const avl::Path& inPath,
 const avl::Line2D& inLine,
 avl::Profile& outProjectionProfile,
 atl::Array<avl::Segment2D>& diagProjectionSegments
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inLine	const Line2D&		Input line to project to
←	outProjectionProfile	Profile&		Output path projection
🔍	diagProjectionSegments	Array<Segment2D>&		Segments corresponding to every profile value

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

RescalePath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates each point of a path proportionally to its distance to a reference point.

Syntax

```
void avl::RescalePath
(
 const avl::Path& inPath,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inReferencePoint	Optional<const Point2D&>	NIL	The point to which all distances change linearly (the mass center by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPath	Path&		Output path

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

RescalePathArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates each point of each path proportionally to its distance to a reference point.

Syntax

```
void avl::RescalePathArray
(
 const atl::Array<avl::Path>& inPaths,
 atl::Optional<const avl::Point2D&> inReferencePoint,
 float inScale,
 bool inInverse,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inReferencePoint	Optional<const Point2D&>	NIL	The point to which all distances change linearly (the mass center by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPaths	Array<Path>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPaths** and **outPaths**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Reference point cannot be computed in RescalePathArray.

ReversePath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reverses the order of points in a path.

Syntax

```
void avl::ReversePath
(
 avl::Path& ioPath
)
```

Parameters

	Name	Type	Default	Description
↔	ioPath	Path&		

RotatePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates a path clockwise around a center point.

Syntax

```
void avl::RotatePath
(
 const avl::Path& inPath,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 avl::Path& outPath
)
```

Parameters

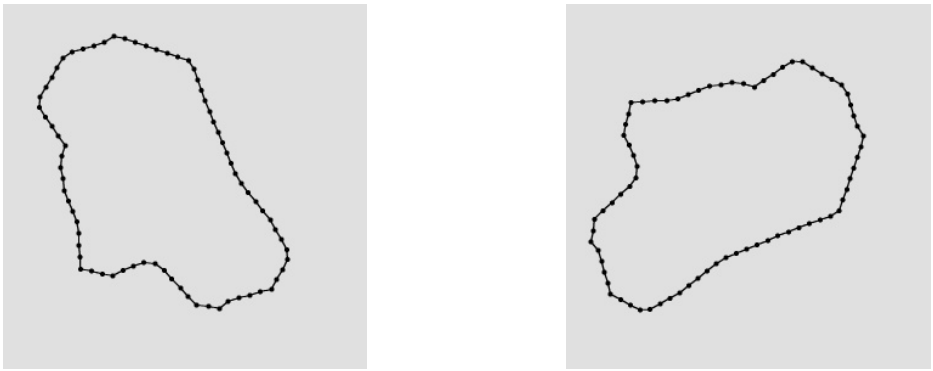
	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the mass center by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outPath	Path&		Output path

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

Examples



RotatePath *run on the sample paths with* ***inAngle*** *= 90,* ***inCenter*** *= Nil.*

See Also

- TranslatePath - Translates a path by a vector.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

RotatePathArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates an array of paths clockwise around a center point.

Syntax

```
void avl::RotatePathArray
(
 const atl::Array<avl::Path>& inPaths,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 bool inInverse,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inCenter	Optional<const Point2D&>	NIL	Center of rotation (the mass center by default)
→	inAngle	float		Clockwise rotation angle
→	inInverse	bool		Switches to the inverse operation
←	outPaths	Array<Path>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPaths** and **outPaths**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Center of rotation cannot be computed in RotatePathArray.

ShiftPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Moves every vertex of path along bisector of the angle between incident segments.

Syntax

```
void avl::ShiftPath
(
 const avl::Path& inPath,
 float inDistance,
 avl::ShiftDirection::Type inDirection,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inDistance	float		
→	inDirection	ShiftDirection::Type		
←	outPath	Path&		Output path

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

TranslatePath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a path by a vector.

Syntax

```
void avl::TranslatePath
(
 const avl::Path& inPath,
 const avl::Vector2D& inDelta,
 bool inInverse,
 avl::Path& outPath
)
```

Parameters

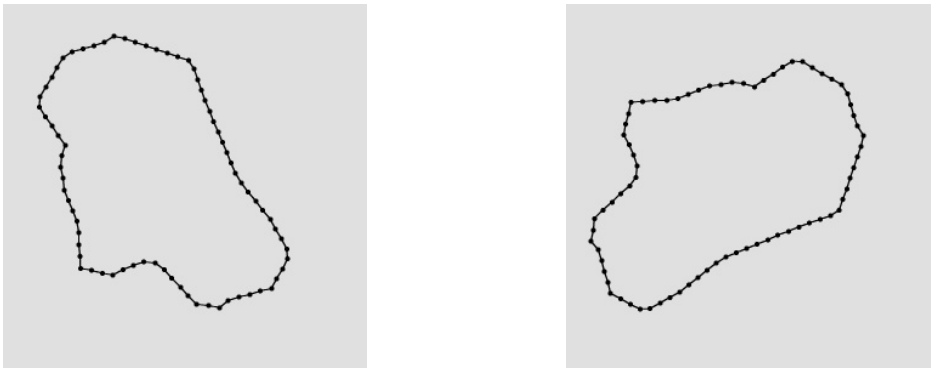
	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPath	Path&		Output path

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

Examples



TranslatePath *run on the sample paths with* ***inDelta*** *= Vector2D(50,0).*

See Also

- RotatePath - Rotates a path clockwise around a center point.
- AlignPath - Moves a path from a local coordinate system to the absolute one.

TranslatePathArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates an array of paths by a vector.

Syntax

```
void avl::TranslatePathArray
(
 const atl::Array<avl::Path>& inPaths,
 const avl::Vector2D& inDelta,
 bool inInverse,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
→	inDelta	const Vector2D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPaths	Array<Path>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPaths** and **outPaths**

Read more about In-place Computation.

Also in AVL Lite

TransposePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Flips and rotates a path so that x-coordinates are exchanged with y-coordinates.

Syntax

```
void avl::TransposePath
(
 const avl::Path& inPath,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outPath	Path&		Output path

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPath** and **outPath**

Read more about In-place Computation.

AlignPoint3DArrayToPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates an array of 3D points with a rotation that transforms the input plane to be parallel to XY plane.

Syntax

```
void avl::AlignPoint3DArrayToPlane
(
 const atl::Array<avl::Point3D>& inPoints,
 const avl::Plane3D& inPlane,
 atl::Array<avl::Point3D>& outPoints,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL,
 atl::Optional<avl::Matrix&> outInvertedTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
→	inPlane	const Plane3D&		The plane that determines rotation transform
←	outPoints	Array<Point3D>&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to align the input points
←	outInvertedTransform	Optional<Matrix&>	NIL	Matrix of the transform rotating the output points to the input ones

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**, **outInvertedTransform**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in AlignPoint3DArrayToPlane.

Box2DToBox3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D box onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Box2DToBox3D_AxesPlane
(
 const avl::Box& inBox2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Box3D& outBox3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inBox2D	const Box&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outBox3D	Box3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

Box3DToBox2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D box onto a plane defined by coordinate axes.

Syntax

```
void avl::Box3DToBox2D_AxesPlane
(
 const avl::Box3D& inBox3D,
 avl::PlaneType::Type inPlaneType,
 avl::Box& outBox2D,
 atl::Optional<avl::Rectangle2D&> outRectangle2D = atl::NIL,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
→	inPlaneType	PlaneType::Type		
←	outBox2D	Box&		
←	outRectangle2D	Optional<Rectangle2D&>	NIL	
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRectangle2D**, **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

Circle2DToCircle3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D circle onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Circle2DToCircle3D_AxesPlane
(
 const avl::Circle2D& inCircle2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Circle3D& outCircle3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inCircle2D	const Circle2D&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outCircle3D	Circle3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Circle3DToCircle2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D circle onto a plane defined by coordinate axes.

Syntax

```
void avl::Circle3DToCircle2D_AxesPlane
(
 const avl::Circle3D& inCircle3D,
 avl::PlaneType::Type inPlaneType,
 avl::Circle2D& outCircle2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inPlaneType	PlaneType::Type		
←	outCircle2D	Circle2D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Line2DToLine3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D line onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Line2DToLine3D_AxesPlane
(
 const avl::Line2D& inLine2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Line3D& outLine3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inLine2D	const Line2D&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outLine3D	Line3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

Line3DToLine2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D line onto a plane defined by coordinate axes.

Syntax

```
void avl::Line3DToLine2D_AxesPlane
(
 const avl::Line3D& inLine3D,
 avl::PlaneType::Type inPlaneType,
 avl::Line2D& outLine2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inPlaneType	PlaneType::Type		
←	outLine2D	Line2D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

MirrorPoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Mirrors a point according to the input plane.

Syntax

```
void avl::MirrorPoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Plane3D& inPlane,
 avl::Point3D& outPoint3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inPlane	const Plane3D&		The plane being a mirror
←	outPoint3D	Point3D&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to mirror the input point

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in MirrorPoint3D.

MirrorPoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Mirrors each point from the array according to the input plane.

Syntax

```
void avl::MirrorPoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Plane3D& inPlane,
 atl::Array<avl::Point3D>& outPoints3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inPlane	const Plane3D&		The plane being a mirror
←	outPoints3D	Array<Point3D>&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to mirror the input points

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in MirrorPoint3DArray.

Point2DToPoint3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D point onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Point2DToPoint3D_AxesPlane
(
 const avl::Point2D& inPoint2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Point3D& outPoint3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint2D	const Point2D&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outPoint3D	Point3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Point3DToPoint2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D point onto a plane defined by coordinate axes.

Syntax

```
void avl::Point3DToPoint2D_AxesPlane
(
 const avl::Point3D& inPoint3D,
 avl::PlaneType::Type inPlaneType,
 avl::Point2D& outPoint2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inPlaneType	PlaneType::Type		
←	outPoint2D	Point2D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Points2DToPoints3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects an array of 2D points onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Points2DToPoints3D_AxesPlane
(
 const atl::Array<avl::Point2D>& inPoints2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 atl::Array<avl::Point3D>& outPoints3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints2D	const Array<Point2D>&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outPoints3D	Array<Point3D>&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Points3DToPoints2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects an array of 3D points onto a plane defined by coordinate axes.

Syntax

```
void avl::Points3DToPoints2D_AxesPlane
(
 const atl::Array<avl::Point3D>& inPoints3D,
 avl::PlaneType::Type inPlaneType,
 atl::Array<avl::Point2D>& outPoints2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inPlaneType	PlaneType::Type		
←	outPoints2D	Array<Point2D>&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

ProjectLineOntoPlane3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a line 3D onto a plane.

Syntax

```
void avl::ProjectLineOntoPlane3D
(
 const avl::Line3D& inLine3D,
 const avl::Plane3D& inPlane,
 avl::Line3D& outLineOnPlane
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inPlane	const Plane3D&		
←	outLineOnPlane	Line3D&		Line in 3D projected on a plane orthogonally

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot project line perpendicular to plane in ProjectLineOntoPlane3D.
DomainError	Indefinite line on input in ProjectLineOntoPlane3D.
DomainError	Indefinite plane on input in ProjectLineOntoPlane3D.

ProjectPoint2DOntoPlane3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a point on a plane Z=0 onto a given plane, translating it parallel to Z axis.

Syntax

```
void avl::ProjectPoint2DOntoPlane3D
(
 const avl::Point2D& inPoint2D,
 const avl::Plane3D& inPlane,
 avl::Point3D& outPointOnPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPoint2D	const Point2D&		
→	inPlane	const Plane3D&		
←	outPointOnPlane	Point3D&		Point projected on a plane parallel to Z axis

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in ProjectPoint2DOntoPlane3D.
DomainError	Point cannot be projected in ProjectPoint2DOntoPlane3D.

ProjectPointOnLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a point 3D onto a line in 3D.

Syntax

```
void avl::ProjectPointOnLine3D
(
 const avl::Point3D& inPoint3D,
 const avl::Line3D& inLine3D,
 avl::Point3D& outPointOnLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inLine3D	const Line3D&		
←	outPointOnLine3D	Point3D&		Point projected on a line orthogonally

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in ProjectPointOnLine3D.

ProjectPointOntoPlane3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a point 3D onto a plane.

Syntax

```
void avl::ProjectPointOntoPlane3D
(
 const avl::Point3D& inPoint3D,
 const avl::Plane3D& inPlane,
 avl::Point3D& outPointOnPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inPlane	const Plane3D&		
←	outPointOnPlane	Point3D&		Point projected on a plane orthogonally

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in ProjectPointOntoPlane3D.

ProjectPointOrthogonal

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Converts a point through a simple orthogonal projection, parallel to the Z axis.

Syntax

```
void avl::ProjectPointOrthogonal
(
 const avl::Point3D& inPoint3D,
 const avl::Point2D& inCenter,
 avl::Point2D& outPoint2D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inCenter	const Point2D&		Center of projection, i.e. the target for projected points (0, 0, z)
←	outPoint2D	Point2D&		

ProjectPointPerspective

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Converts a point through a perspective projection, parallel to the Z axis.

Syntax

```
void avl::ProjectPointPerspective
(
 const avl::Point3D& inPoint3D,
 const avl::Point2D& inCenter,
 const avl::Point3D& inFocalPoint,
 float inFocalLength,
 avl::Point2D& outPoint2D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inCenter	const Point2D&		Center of projection, i.e. the target for projected points (x_focal, y_focal, z)
→	inFocalPoint	const Point3D&		The camera center, i.e. the point we measure (x, y, z) against
→	inFocalLength	float		The multiplier for the x and y coordinates, which is divided by z. If negative, projects in opposite direction.
←	outPoint2D	Point2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Projected point coplanar with the focal point, but not equal to it in ProjectPointPerspective.

RescaleBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the distances of box in 3D to a reference point.

Syntax

```
void avl::RescaleBox3D
(
 const avl::Box3D& inBox3D,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
→	inReferencePoint	const Point3D&		Point to which the distances will be changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outBox3D	Box3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox3D** and **outBox3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a box in RescaleBox3D.

RescaleCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes radius of a circle in 3D and translates its center in relation to a reference point.

Syntax

```
void avl::RescaleCircle3D
(
 const avl::Circle3D& inCircle3D,
 atl::Optional<const avl::Point3D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inReferencePoint	Optional<const Point3D&>	NIL	The point to which the distance of the circle center is changed (circle center by default)
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outCircle3D	Circle3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle3D** and **outCircle3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in RescaleCircle3D.
DomainError	Scale cannot be zero in an inverse scaling of a circle in RescaleCircle3D.

RescaleLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the input line in 3D distance to a reference point.

Syntax

```
void avl::RescaleLine3D
(
 const avl::Line3D& inLine3D,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		Input line in 3D
→	inReferencePoint	const Point3D&		The point to which the distance of line in 3D is changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outLine3D	Line3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine3D** and **outLine3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in RescaleLine3D.
DomainError	Scale cannot be zero in an inverse rescaling of a line in RescaleLine3D.

RescalePlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the input plane distance to a reference point.

Syntax

```
void avl::RescalePlane
(
 const avl::Plane3D& inPlane,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
→	inReferencePoint	const Point3D&		The point to which the distance of plane is changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPlane	Plane3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPlane** and **outPlane**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in RescalePlane.
DomainError	Scale cannot be zero in an inverse rescaling of a plane in RescalePlane.

RescalePoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the distance of a point to a reference point.

Syntax

```
void avl::RescalePoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inReferencePoint	const Point3D&		Point to which the distance will be changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint3D** and **outPoint3D**, **inReferencePoint** and **outPoint3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a point.

RescalePoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the distances of array points to a reference point.

Syntax

```
void avl::RescalePoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 atl::Array<avl::Point3D>& outPoints3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inReferencePoint	const Point3D&		Point to which the distances will be changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outPoints3D	Array<Point3D>&		

Hardware Acceleration

This operation is optimized for SSE2 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a point.

RescaleSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Lengthens or shortens a segment in 3D relatively.

Syntax

```
void avl::RescaleSegment3D
(
 const avl::Segment3D& inSegment3D,
 atl::Optional<const avl::Point3D&> inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		Input segment in 3D
→	inReferencePoint	Optional<const Point3D&>	NIL	The point to which all distances change linearly (the mass center by default)
→	inScale	float	1.0f	Scaling factor (negative values invert the segment)
→	inInverse	bool		Switches to the inverse operation
←	outSegment3D	Segment3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment3D** and **outSegment3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a segment in RescaleSegment3D.

RescaleVector3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Lengthens or shortens a 3D vector relatively preserving its direction.

Syntax

```
void avl::RescaleVector3D
(
 const avl::Vector3D& inVector3D,
 float inScale,
 bool inInverse,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outVector3D	Vector3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inVector3D** and **outVector3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse scaling of vector in RescaleVector3D.

ResizeBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the dimensions of a box in 3D.

Syntax

```
void avl::ResizeBox3D
(
 const avl::Box3D& inBox3D,
 const avl::Anchor3D& inAnchor,
 atl::Optional<float> inNewXLength,
 atl::Optional<float> inNewYLength,
 atl::Optional<float> inNewZLength,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox3D	const Box3D&			Input box in 3D
→	inAnchor	const Anchor3D&			Point of the box in 3D which position will not change
→	inNewXLength	Optional<float>	0.0 – ∞	NIL	Target length of the box in x-coordinate
→	inNewYLength	Optional<float>	0.0 – ∞	NIL	Target length of the box in y-coordinate
→	inNewZLength	Optional<float>	0.0 – ∞	NIL	Target length of the box in z-coordinate
←	outBox3D	Box3D&			Resized box

ResizeBox3D_Delta

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the dimensions of a box in 3D by adding some values.

Syntax

```
void avl::ResizeBox3D_Delta
(
 const avl::Box3D& inBox3D,
 const avl::Anchor3D& inAnchor,
 float inXLengthDelta,
 float inYLengthDelta,
 float inZLengthDelta,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		Input box
→	inAnchor	const Anchor3D&		Point of the box in 3D which position will not change
→	inXLengthDelta	float	0.0f	Value added to length of the box in X axis
→	inYLengthDelta	float	0.0f	Value added to length of the box in X axis
→	inZLengthDelta	float	0.0f	Value added to length of the box in X axis
←	outBox3D	Box3D&		Resized box

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative box dimensions in ResizeBox3D_Delta.

ResizeBox3D_Relative

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Resizes a box in 3D to relatively defined dimensions.

Syntax

```
void avl::ResizeBox3D_Relative
(
 const avl::Box3D& inBox3D,
 const avl::Anchor3D& inAnchor,
 float inXScale,
 float inYScale,
 float inZScale,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inBox3D	const Box3D&			Input box in 3D
➡	inAnchor	const Anchor3D&			Point of the box in 3D which position will not change
➡	inXScale	float	0.0 – ∞	1.0f	Scale factor in X axis
➡	inYScale	float	0.0 – ∞	1.0f	Scale factor in Y axis
➡	inZScale	float	0.0 – ∞	1.0f	Scale factor in Z axis
⬅	outBox3D	Box3D&			Resized box

ResizeCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes radius of a circle in 3D.

Syntax

```
void avl::ResizeCircle3D
(
 const avl::Circle3D& inCircle3D,
 float inNewSize,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inCircle3D	const Circle3D&			
➡	inNewSize	float	0.0 – ∞	1.0f	New value for radius
⬅	outCircle3D	Circle3D&			

ResizeCircle3D_Delta

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes radius of a circle in 3D by adding a value.

Syntax

```
void avl::ResizeCircle3D_Delta
(
 const avl::Circle3D& inCircle3D,
 float inDelta,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inDelta	float	0.0f	Value added to circle radius
←	outCircle3D	Circle3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative circle radius in ResizeCircle3D_Delta.

ResizeSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Lengthens or shortens a segment in 3D to a new length preserving its orientation and center point.

Syntax

```
void avl::ResizeSegment3D
(
 const avl::Segment3D& inSegment3D,
 float inNewLength,
 float inAnchor,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment3D	const Segment3D&			
→	inNewLength	float	0.0 – ∞	1.0f	
→	inAnchor	float	– ∞ – ∞	0.5f	Anchor point, 0 means the beginning, 1 means the end of the segment
←	outSegment3D	Segment3D&			

ResizeSegment3D_Delta

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes length of a segment in 3D by adding a value preserving its orientation and center point.

Syntax

```
void avl::ResizeSegment3D_Delta
(
 const avl::Segment3D& inSegment3D,
 float inDelta,
 float inAnchor,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment3D	const Segment3D&			
→	inDelta	float		0.0f	Value added to segment length
→	inAnchor	float	$-\infty$ – ∞	0.5f	Anchor point, 0 means the beginning, 1 means the end of the segment
←	outSegment3D	Segment3D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative segment length in ResizeSegment3D_Delta.

ResizeVector3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Lengthens or shortens a 3D vector preserving its direction.

Syntax

```
void avl::ResizeVector3D
(
 const avl::Vector3D& inVector3D,
 float inNewLength,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVector3D	const Vector3D&			
→	inNewLength	float	0.0 – ∞	1.0f	
←	outVector3D	Vector3D&			

ResizeVector3D_Delta

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Extends length of a 3D vector by adding a value preserving its direction.

Syntax

```
void avl::ResizeVector3D_Delta
(
 const avl::Vector3D& inVector3D,
 float inDelta,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
➡	inVector3D	const Vector3D&		
➡	inDelta	float	0.0f	Value added to vector length
⬅	outVector3D	Vector3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative vector length in ResizeVector3D_Delta.

ReverseSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Swaps the two endpoints of a segment in 3D.

Syntax

```
void avl::ReverseSegment3D
(
 const avl::Segment3D& inSegment3D,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
➡	inSegment3D	const Segment3D&		
⬅	outSegment3D	Segment3D&		

RotateCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a circle in 3D around an axis in 3D.

Syntax

```
void avl::RotateCircle3D
(
 const avl::Circle3D& inCircle3D,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outCircle3D	Circle3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle3D** and **outCircle3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in RotateCircle3D.
DomainError	Indefinite line on input in RotateCircle3D.

RotateCircle3D_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a circle in 3D around a segment (the axis) in 3D.

Syntax

```
void avl::RotateCircle3D_AroundSegment
(
 const avl::Circle3D& inCircle3D,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outCircle3D	Circle3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle3D** and **outCircle3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty segment on input in RotateCircle3D_AroundSegment.
DomainError	Indefinite circle on input in RotateCircle3D_AroundSegment.

RotateLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a line in 3D around an axis in 3D.

Syntax

```
void avl::RotateLine3D
(
 const avl::Line3D& inLine3D,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outLine3D	Line3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine3D** and **outLine3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in RotateLine3D.

RotateLine3D_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a line in 3D around a segment (the axis) in 3D.

Syntax

```
void avl::RotateLine3D_AroundSegment
(
 const avl::Line3D& inLine3D,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outLine3D	Line3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine3D** and **outLine3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty segment on input in RotateLine3D_AroundSegment.
DomainError	Indefinite line on input in RotateLine3D_AroundSegment.

RotatePlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a plane in 3D around an axis in 3D.

Syntax

```
void avl::RotatePlane
(
 const avl::Plane3D& inPlane,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPlane	Plane3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPlane** and **outPlane**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in RotatePlane.
DomainError	Indefinite plane on input in RotatePlane.

RotatePlane_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a plane in 3D around a segment (the axis) in 3D.

Syntax

```
void avl::RotatePlane_AroundSegment
(
 const avl::Plane3D& inPlane,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPlane	Plane3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPlane** and **outPlane**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty segment on input in RotatePlane_AroundSegment.
DomainError	Indefinite plane on input in RotatePlane_AroundSegment.

RotatePoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a 3D point around an axis in 3D.

Syntax

```
void avl::RotatePoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Point3D& outPoint3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		
←	outTransform	Optional<Matrix&>	NIL	

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint3D** and **outPoint3D**

Read more about In-place Computation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

RotatePoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates an array of 3D points around an axis in 3D.

Syntax

```
void avl::RotatePoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 atl::Array<avl::Point3D>& outPoints3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPoints3D	Array<Point3D>&		
←	outTransform	Optional<Matrix&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

RotatePoint3DArray_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates an array of 3D points around a segment (the axis).

Syntax

```
void avl::RotatePoint3DArray_AroundSegment
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 atl::Array<avl::Point3D>& outPoints3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPoints3D	Array<Point3D>&		
←	outTransform	Optional<Matrix&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

RotatePoint3D_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a 3D point around a segment (the axis).

Syntax

```
void avl::RotatePoint3D_AroundSegment
(
 const avl::Point3D& inPoint3D,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Point3D& outPoint3D,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		
←	outTransform	Optional<Matrix&>	NIL	

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint3D** and **outPoint3D**

Read more about In-place Computation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

RotateSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a segment in 3D around an axis in 3D.

Syntax

```
void avl::RotateSegment3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outSegment3D	Segment3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment3D** and **outSegment3D**

Read more about In-place Computation.

RotateSegment3D_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a segment in 3D around a segment (the axis) in 3D.

Syntax

```
void avl::RotateSegment3D_AroundSegment
(
 const avl::Segment3D& inSegment3D,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outSegment3D	Segment3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment3D** and **outSegment3D**

Read more about In-place Computation.

RotateVector3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a 3D vector around another 3D vector (the axis).

Syntax

```
void avl::RotateVector3D
(
 const avl::Vector3D& inVector3D,
 const avl::Vector3D& inAxisVector,
 float inAngle,
 bool inInverse,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
→	inAxisVector	const Vector3D&		Vector to rotate around
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outVector3D	Vector3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inVector3D** and **outVector3D**, **inAxisVector** and **outVector3D**

Read more about In-place Computation.

Segment2DToSegment3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D segment onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Segment2DToSegment3D_AxesPlane
(
 const avl::Segment2D& inSegment2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Segment3D& outSegment3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSegment2D	const Segment2D&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outSegment3D	Segment3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Segment3DToSegment2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D segment onto a plane defined by coordinate axes.

Syntax

```
void avl::Segment3DToSegment2D_AxesPlane
(
 const avl::Segment3D& inSegment3D,
 avl::PlaneType::Type inPlaneType,
 avl::Segment2D& outSegment2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inPlaneType	PlaneType::Type		
←	outSegment2D	Segment2D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Segments2DToSegments3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects an array of 2D segments onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Segments2DToSegments3D_AxesPlane
(
 const atl::Array<avl::Segment2D>& inSegments2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 atl::Array<avl::Segment3D>& outSegments3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSegments2D	const Array<Segment2D>&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outSegments3D	Array<Segment3D>&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Segments3DToSegments2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects an array of 3D segments onto a plane defined by coordinate axes.

Syntax

```
void avl::Segments3DToSegments2D_AxesPlane
(
 const atl::Array<avl::Segment3D>& inSegments3D,
 avl::PlaneType::Type inPlaneType,
 atl::Array<avl::Segment2D>& outSegments2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSegments3D	const Array<Segment3D>&		
→	inPlaneType	PlaneType::Type		
←	outSegments2D	Array<Segment2D>&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

SplitPointsByPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Separates the points being on one side of the input plane from the others.

Syntax

```
void avl::SplitPointsByPlane
(
 const atl::Array<avl::Point3D>& inPoints,
 const avl::Plane3D& inPlane,
 atl::Array<avl::Point3D>& outPoints1,
 atl::Array<avl::Point3D>& outPoints2
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		Input points
→	inPlane	const Plane3D&		Plane used for splitting
←	outPoints1	Array<Point3D>&		Points with positive signed distance to the input plane
←	outPoints2	Array<Point3D>&		Points with negative signed distance to the input plane

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SplitPointsByPlane.

TransformCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a 3D circle.

Syntax

```
void avl::TransformCircle3D
(
 const avl::Circle3D& inCircle3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outCircle3D	Circle3D&		

TransformLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a 3D line.

Syntax

```
void avl::TransformLine3D
(
 const avl::Line3D& inLine3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outLine3D	Line3D&		

TransformPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a plane.

Syntax

```
void avl::TransformPlane
(
 const avl::Plane3D& inPlane,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outPlane	Plane3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Singular matrix not allowed in TransformPlane.
DomainError	Transformation matrix size must be 3x3 or 4x4 in TransformPlane.

TransformPoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a 3D point.

Syntax

```
void avl::TransformPoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Transformation matrix size must be 3x3 or 4x4 in 3D point transform.

TransformPoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to an array of 3D points.

Syntax

```
void avl::TransformPoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 atl::Array<avl::Point3D>& outPoints3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outPoints3D	Array<Point3D>&		

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Transformation matrix size must be 3x3 or 4x4 in 3D point transform.

TransformSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a 3D segment.

Syntax

```
void avl::TransformSegment3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outSegment3D	Segment3D&		

TransformVector3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a 3D vector.

Syntax

```
void avl::TransformVector3D
(
 const avl::Vector3D& inVector3D,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outVector3D	Vector3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Singular matrix not allowed for inverse transform in TransformVector3D.
DomainError	Transformation matrix size must be 3x3 or 4x4 in TransformVector3D.

TranslateBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Shifts a box in 3D by a vector.

Syntax

```
void avl::TranslateBox3D
(
 const avl::Box3D& inBox3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		Input box in 3D
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outBox3D	Box3D&		Shifted box

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox3D** and **outBox3D**

Read more about In-place Computation.

TranslateCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Shifts a circle in 3D by a vector.

Syntax

```
void avl::TranslateCircle3D
(
 const avl::Circle3D& inCircle3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Circle3D& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		Input circle
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outCircle3D	Circle3D&		Shifted circle

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inCircle3D** and **outCircle3D**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in TranslateCircle3D.

TranslateLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Shifts a line in 3D by a vector.

Syntax

```
void avl::TranslateLine3D
(
 const avl::Line3D& inLine3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		Input line in 3D
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outLine3D	Line3D&		Shifted line

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLine3D** and **outLine3D**

Read more about In-place Computation.

TranslatePlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Shifts a plane in 3D by a vector.

Syntax

```
void avl::TranslatePlane
(
 const avl::Plane3D& inPlane,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		Input plane
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPlane	Plane3D&		Shifted plane

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPlane** and **outPlane**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in TranslatePlane.

TranslatePoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Translates a point by a vector.

Syntax

```
void avl::TranslatePoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoint3D** and **outPoint3D**

Read more about In-place Computation.

TranslatePoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Translates an array of points by a vector.

Syntax

```
void avl::TranslatePoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 atl::Array<avl::Point3D>& outPoints3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outPoints3D	Array<Point3D>&		

Hardware Acceleration

This operation is optimized for SSE2 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

TranslatePoint3D_Toward

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Translates a point in 3D towards another point in 3D by a specified distance.

Syntax

```
void avl::TranslatePoint3D_Toward
(
 const avl::Point3D& inPoint3D,
 const avl::Point3D& inTargetPoint,
 float inDistance,
 bool inInverse,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inTargetPoint	const Point3D&		Defines the direction of the translation
→	inDistance	float		The distance between inPoint3D and outPoint3D
→	inInverse	bool		Switches to the inverse operation
←	outPoint3D	Point3D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inTargetPoint** and **outPoint3D**, **inPoint3D** and **outPoint3D**

Read more about In-place Computation.

TranslateSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Shifts a segment in 3D by a vector.

Syntax

```
void avl::TranslateSegment3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		Input segment in 3D
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outSegment3D	Segment3D&		Shifted segment

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inSegment3D** and **outSegment3D**

Read more about In-place Computation.

TrimLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Creates a segment contained in a box in 3D from a line in 3D.

Syntax

```
void avl::TrimLine3D
(
 const avl::Line3D& inLine3D,
 const avl::Box3D& inBox3D,
 atl::Conditional<avl::Segment3D>& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inBox3D	const Box3D&		
←	outSegment3D	Conditional<Segment3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in TrimLine3D.

TrimPoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes points not contained in a box in 3D from an array.

Syntax

```
void avl::TrimPoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints3D,
 const avl::Box3D& inBox3D,
 atl::Array<avl::Point3D>& outPoints3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints3D	const Array<Point3D>&		
→	inBox3D	const Box3D&		
←	outPoints3D	Array<Point3D>&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inPoints3D** and **outPoints3D**

Read more about In-place Computation.

TrimSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Creates a segment contained in a box in 3D from another segment in 3D.

Syntax

```
void avl::TrimSegment3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Box3D& inBox3D,
 atl::Conditional<avl::Segment3D>& outSegment3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inBox3D	const Box3D&		
←	outSegment3D	Conditional<Segment3D>&		

Vector2DToVector3D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 2D vector onto a plane defined by 3D coordinate axes.

Syntax

```
void avl::Vector2DToVector3D_AxesPlane
(
 const avl::Vector2D& inVector2D,
 avl::PlaneType::Type inPlaneType,
 float inCoordinateValue,
 avl::Vector3D& outVector3D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inVector2D	const Vector2D&		
→	inPlaneType	PlaneType::Type		
→	inCoordinateValue	float		Coordinate of the chosen axes plane
←	outVector3D	Vector3D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

Vector3DToVector2D_AxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects a 3D vector onto a plane defined by coordinate axes.

Syntax

```
void avl::Vector3DToVector2D_AxesPlane
(
 const avl::Vector3D& inVector3D,
 avl::PlaneType::Type inPlaneType,
 avl::Vector2D& outVector2D,
 atl::Optional<avl::Plane3D&> outProjectionPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
→	inPlaneType	PlaneType::Type		
←	outVector2D	Vector2D&		
←	outProjectionPlane	Optional<Plane3D&>	NIL	Plane the input is projected onto

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect plane type.

AlignPoint3DGridToPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a grid of 3D points with a rotation that transforms the input plane to be parallel to XY plane.

Syntax

```
void avl::AlignPoint3DGridToPlane
(
 const avl::Point3DGrid& inGrid,
 const avl::Plane3D& inPlane,
 avl::Point3DGrid& outGrid,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL,
 atl::Optional<avl::Matrix&> outInvertedTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inPlane	const Plane3D&		The plane that determines rotation transform
←	outGrid	Point3DGrid&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to align the input grid
←	outInvertedTransform	Optional<Matrix&>	NIL	Matrix of the transform rotating the output grid to the input one

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**, **outInvertedTransform**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in AlignPoint3DGridToPlane.

CropPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes from the grid points that are not contained in a given rectangular box.

Syntax

```
void avl::CropPoint3DGrid
(
 const avl::Point3DGrid& inPoint3DGrid,
 const avl::ValueLimits& inXLimits,
 const avl::ValueLimits& inYLimits,
 const avl::ValueLimits& inZLimits,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
→	inXLimits	const ValueLimits&		
→	inYLimits	const ValueLimits&		
→	inZLimits	const ValueLimits&		
←	outPoint3DGrid	Point3DGrid&		

CropPoint3DGridByNeighborsProximity

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes from the grid points that are too distant from their neighbor points.

Syntax

```
void avl::CropPoint3DGridByNeighborsProximity
(
 const avl::Point3DGrid& inPoint3DGrid,
 const int inNeighborRadius,
 const float inMaxDistance,
 avl::Metric3D::Type inMetric,
 const float inMinNeighborRatio,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid	const Point3DGrid&			
→	inNeighborRadius	const int	1 – ∞	1	Radius of neighbors to search for real neighbors
→	inMaxDistance	const float	0.0 – ∞	2.0f	Maximal distance from another point to consider them real neighbors
→	inMetric	Metric3D::Type		Z	Metric used for measuring distance between points
→	inMinNeighborRatio	const float	0.0 – 1.0	1.0f	Fraction of valid neighbors in a given radius that have to be real neighbors
←	outPoint3DGrid	Point3DGrid&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect metric in CropPoint3DGridByNeighborsProximity.

CropPoint3DGridByPlaneProximity

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes from the grid points that are too distant from a given plane.

Syntax

```
void avl::CropPoint3DGridByPlaneProximity
(
 const avl::Point3DGrid& inPoint3DGrid,
 const avl::Plane3D& inPlane,
 const float inMaxDistance,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
→	inPlane	const Plane3D&		
→	inMaxDistance	const float		Maximal distance from a given plane
←	outPoint3DGrid	Point3DGrid&		

CropPoint3DGridToRegion

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes points that are not represented in a given region of the input grid.

Syntax

```
void avl::CropPoint3DGridToRegion
(
 const avl::Point3DGrid& inPoint3DGrid,
 const avl::Region& inRegion,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
→	inRegion	const Region&		Input region
←	outPoint3DGrid	Point3DGrid&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Input region exceeds Point3DGrid dimensions in CropPoint3DGridToRegion.

JoinPoint3DGrids

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Combines two point grids into one.

Syntax

```
void avl::JoinPoint3DGrids
(
 const avl::Point3DGrid& inPoint3DGrid1,
 const avl::Point3DGrid& inPoint3DGrid2,
 atl::Optional<int> inDeltaX,
 atl::Optional<int> inDeltaY,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid1	const Point3DGrid&			
→	inPoint3DGrid2	const Point3DGrid&			
→	inDeltaX	Optional<int>	0 – ∞	NIL	First index offset for second grid; if set to Nil, first grid's width is chosen
→	inDeltaY	Optional<int>	0 – ∞	0	Second index offset for second grid; if set to Nil, first grid's height is chosen
←	outPoint3DGrid	Point3DGrid&			

Description

The operation adds points from the second input grid to the first one, increasing the grid's dimensions if necessary. The **inDeltaX** and **inDeltaY** parameters determine the offsets added to indices of the second grid. The second grid's points will never overwrite points from the first grid, so if both grids have same dimensions and both **inDeltaX** and **inDeltaY** equal 0, no point from the second grid will be added. If **inDeltaX** is set to Nil, the width of the first input grid is chosen. Similarly, if **inDeltaY** is set to Nil, the height of the first input grid is chosen as the offset.

If the intention is to keep all points from both input grids, one of the offsets should be set to Nil.

MirrorPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Mirrors each grid point according to the input plane.

Syntax

```
void avl::MirrorPoint3DGrid
(
 const avl::Point3DGrid& inGrid,
 const avl::Plane3D& inPlane,
 avl::Point3DGrid& outGrid,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inPlane	const Plane3D&		The plane being a mirror
←	outGrid	Point3DGrid&		
←	outTransform	Optional<Matrix&>	NIL	Matrix of the transform used to mirror the input grid

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in MirrorPoint3DGrid.

RescalePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Changes the distances of grid points to a reference point.

Syntax

```
void avl::RescalePoint3DGrid
(
 const avl::Point3DGrid& inGrid,
 const avl::Point3D& inReferencePoint,
 float inScale,
 bool inInverse,
 avl::Point3DGrid& outGrid
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inReferencePoint	const Point3D&		Point to which the distances will be changed
→	inScale	float	1.0f	Scaling factor
→	inInverse	bool		Switches to the inverse operation
←	outGrid	Point3DGrid&		

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

Errors

List of possible exceptions:

Error type	Description
DomainError	Scale cannot be zero in an inverse rescaling of a point.

RotatePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a grid of 3D points around an axis in 3D.

Syntax

```
void avl::RotatePoint3DGrid
(
 const avl::Point3DGrid& inGrid,
 const avl::Line3D& inAxis,
 float inAngle,
 bool inInverse,
 avl::Point3DGrid& outGrid,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inAxis	const Line3D&		The rotation axis
→	inAngle	float		Clockwise angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outGrid	Point3DGrid&		
←	outTransform	Optional<Matrix&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

RotatePoint3DGrid_AroundSegment

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Rotates a grid of 3D points around an segment3D (the axis) in 3D.

Syntax

```
void avl::RotatePoint3DGrid_AroundSegment
(
 const avl::Point3DGrid& inGrid,
 const avl::Segment3D& inAxisSegment,
 float inAngle,
 bool inInverse,
 avl::Point3DGrid& outGrid,
 atl::Optional<avl::Matrix&> outTransform = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inAxisSegment	const Segment3D&		The rotation axis
→	inAngle	float		Angle of rotation
→	inInverse	bool		Switches to the inverse operation
←	outGrid	Point3DGrid&		
←	outTransform	Optional<Matrix&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTransform**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

SplitPoint3DGridByPlane

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Separates the points being on one side of the input plane from the others.

Syntax

```
void avl::SplitPoint3DGridByPlane
(
 const avl::Point3DGrid& inPoint3DGrid,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Plane3D& inPlane,
 avl::Point3DGrid& outPoint3DGrid1,
 avl::Point3DGrid& outPoint3DGrid2
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inPlane	const Plane3D&		Plane used for splitting
←	outPoint3DGrid1	Point3DGrid&		Grid of points with positive signed distance to the input plane
←	outPoint3DGrid2	Point3DGrid&		Grid of points with negative signed distance to the input plane

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SplitPoint3DGridByPlane.

TransformPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Applies a general transformation expressed by a matrix to a grid of 3D points.

Syntax

```
void avl::TransformPoint3DGrid
(
 const avl::Point3DGrid& inGrid,
 const avl::Matrix& inTransform,
 bool inInverse,
 avl::Point3DGrid& outGrid
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inTransform	const Matrix&		Transformation 3x3 or 4x4 matrix
→	inInverse	bool		Switches to the inverse operation
←	outGrid	Point3DGrid&		

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Transformation matrix size must be 3x3 or 4x4 in 3D point transform.

TranslatePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Translates a grid of points by a vector.

Syntax

```
void avl::TranslatePoint3DGrid
(
 const avl::Point3DGrid& inGrid,
 const avl::Vector3D& inDelta,
 bool inInverse,
 avl::Point3DGrid& outGrid
)
```

Parameters

	Name	Type	Default	Description
→	inGrid	const Point3DGrid&		
→	inDelta	const Vector3D&		Translation vector
→	inInverse	bool		Switches to the inverse operation
←	outGrid	Point3DGrid&		

Hardware Acceleration

This operation is optimized for SSE41 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

28. Region Spatial Transforms

Table of content:

- AlignRegion
- CropRegion
- CropRegionToQuadrangle
- CropRegionToRectangle
- DownsampleRegion
- EnlargeRegionNTimes
- MirrorRegion
- ReflectRegion
- ResizeRegion
- ResizeRegion_Relative
- RotateRegion
- ShearRegion
- ShrinkRegionNTimes
- TranslateRegion
- TransposeRegion
- TrimRegionToPolygon
- TrimRegionToRectangle
- UncropRegion

AlignRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Aligns a region to a coordinate system.

Applications: Most typically used, when there is a region extracted after performing CropImageToRectangle. This filter makes it possible to align the region with the original image.

Syntax

```
void avl::AlignRegion
(
 const avl::Region& inRegion,
 const avl::CoordinateSystem2D& inAlignment,
 bool inInverse,
 atl::Optional<int> inFrameWidth,
 atl::Optional<int> inFrameHeight,
 avl::Region& outAlignedRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inAlignment	const CoordinateSystem2D&			Coordinate system to align to
→	inInverse	bool			Switches to the inverse transform
→	inFrameWidth	Optional<int>	0 – 65535	NIL	Output region's frame width
→	inFrameHeight	Optional<int>	0 – 65535	NIL	Output region's frame height
←	outAlignedRegion	Region&			

In-place Processing

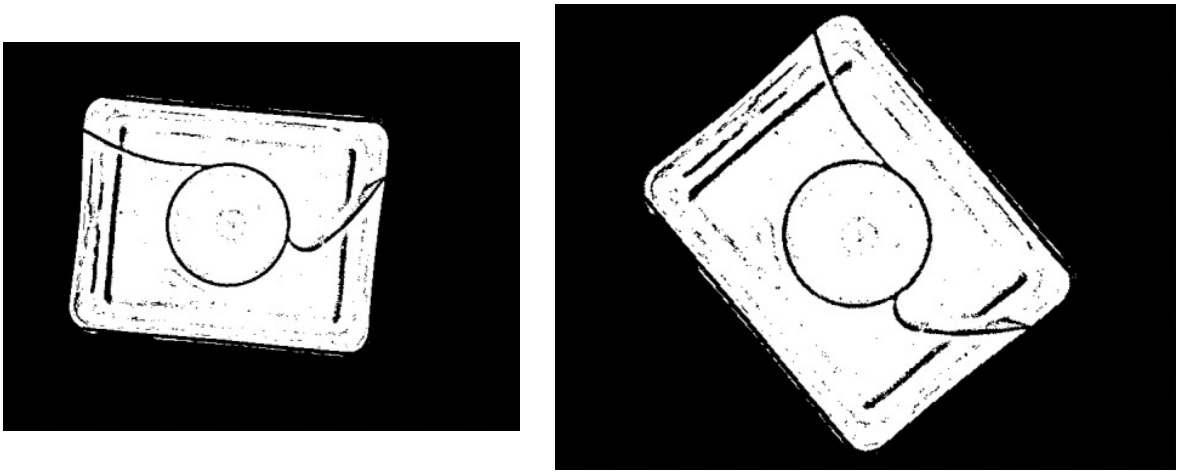
This function supports in-place data processing – you can pass the same reference to **inRegion** and **outAlignedRegion**

Read more about In-place Computation.

Description

AlignRegion applies **inAlignment** transform to an input region.

Examples



__AlignRegion__ performed on the sample region, __inAlignment.Origin__ = (280, −120), __inAlignment.Angle__ = 45, __inAlignment.Scale__ = 1.0 and __inInverse__ = False. The __inAlignment.Origin__ is drawn on the first image in blue.

Remarks

Region is a pixel-precise object, so geometrical transform may cause its deformation. Consider using a closed Path instead, which can be converted to a region in the last step.

See Also

- MirrorRegion – Mirrors a region across vertical or horizontal axis.
- TransposeRegion – Flips and rotates a region so that x-coordinates are exchanged with y-coordinates.
- RotateRegion – Rotates a region around a specified point.

CropRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a region from a rectangular fragment of another one.

Applications: Can be used to obtain a part of a bigger region, but also to enforce specific region frame.

Syntax

```
void avl::CropRegion
(
 const avl::Region& inRegion,
 const avl::Box& inSelection,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inSelection	const Box&		Box defining the range of cropping
←	outRegion	Region&		Output region

Examples

***CropRegion** performed on the sample region with **inSelection** = Box(0,0,200,200).*

See Also

- SetRegionFrame – Changes the width and the height of a region's frame (but does not rescale the content).
- UncropRegion – Inverse of CropRegion.

CropRegionToQuadrangle

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a region from a quadrangular fragment of another one. The quadrangle must be convex.

Syntax

```
void avl::CropRegionToQuadrangle
(
 const avl::Region& inRegion,
 const avl::Path& inQuadrangle,
 atl::Optional<const avl::Size&> inOutputSize,
 atl::Optional<const avl::CoordinateSystem2D&> inQuadrangleAlignment,
 avl::Region& outRegion,
 atl::Optional<avl::Path&> outAlignedShape = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inQuadrangle	const Path&		A convex quadrangle defining a region to be cropped (points must be clockwise)
→	inOutputSize	Optional<const Size&>	NIL	Width and height of the output region
→	inQuadrangleAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the quadrangle to the position of the inspected object
←	outRegion	Region&		Output region
←	outAlignedShape	Optional<Path&>	NIL	The input quadrangle after transformation (in the region coordinates)

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inRegion** and **outRegion**

Read more about In-place Computation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedShape**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Path given as an argument to CropRegionToQuadrangle is not closed.
DomainError	Path given as an argument to CropRegionToQuadrangle should have exactly 4 points.

CropRegionToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a region from a rectangular fragment of another one.

Applications: Can be used to obtain a part of a bigger region, but also to enforce specific region frame.

Syntax

```
void avl::CropRegionToRectangle
(
 const avl::Region& inRegion,
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 avl::Region& outRegion,
 atl::Optional<avl::Rectangle2D&> outAlignedRectangle = atl::NIL,
 atl::Optional<avl::CoordinateSystem2D&> outOutputAlignment = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inRectangle	const Rectangle2D&		Rectangle defining a rotated subregion
→	inRectangleAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the rectangle to the position of the inspected object
←	outRegion	Region&		Output region
←	outAlignedRectangle	Optional<Rectangle2D&>	NIL	Input rectangle after transformation (in the region coordinates)
←	outOutputAlignment	Optional<CoordinateSystem2D&>	NIL	Alignment of the output region

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRegion** and **outRegion**

Read more about In-place Computation.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRectangle**, **outOutputAlignment**.

Read more about Optional Outputs.

DownsampleRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shrinks a region by the factor of two along each axis.

Syntax

```
void avl::DownsampleRegion
(
 const avl::Region& inRegion,
 avl::DownsampleRegionMode::Type inDownsampleRegionMode,
 const int inScaleStep,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inDownsampleRegionMode	DownsampleRegionMode::Type			
→	inScaleStep	const int	0 – 12	1	Defines how many times the region size is divided by 2
←	outRegion	Region&			Output region

See Also

- ShrinkRegionNTimes – Shrinks a region by a natural factor along each axis.
- ResizeRegion – Enlarges or shrinks a region to new dimensions.
- ResizeRegion_Relative – Resizes region relatively along each axis.
- EnlargeRegionNTimes – Enlarges a region by a natural factor.
- DownsampleImage – Shrinks an image by the factor of two along each axis.

EnlargeRegionNTimes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Enlarges a region by a natural factor.

Syntax

```
void avl::EnlargeRegionNTimes
(
 const avl::Region& inRegion,
 int inN,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inN	int	1 – ∞	2	The scaling coefficient
←	outRegion	Region&			Output region

Examples

EnlargeRegionNTimes *performed on the sample region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in EnlargeRegionNTimes.
DomainError	Output region too big in EnlargeRegionNTimes.

MirrorRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Mirrors a region across vertical or horizontal axis.

Syntax

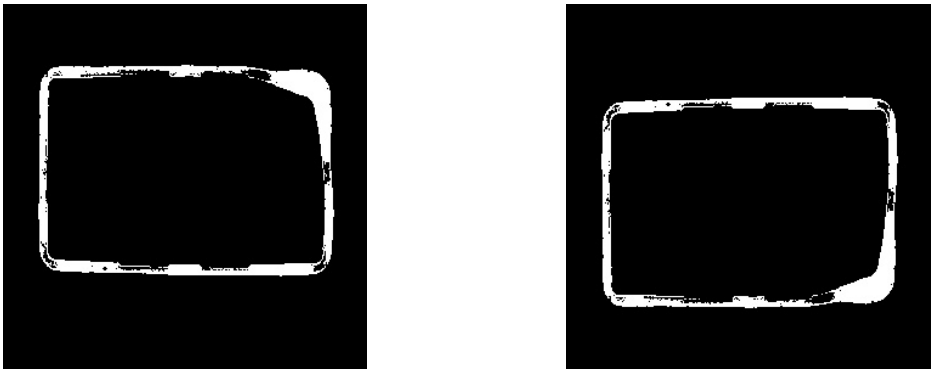
```
void avl::MirrorRegion
(
 const avl::Region& inRegion,
 const avl::MirrorDirection::Type inMirrorDirection,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inMirrorDirection	const MirrorDirection::Type	Horizontal	Reverse the order of region columns (horizontal direction) or rows (vertical direction).
←	outRegion	Region&		Output region

Examples

***MirrorRegion** with **inMirrorDirection** = Horizontal.*



***MirrorRegion** with **inMirrorDirection** = Vertical.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in MirrorRegion.

See Also

- TransposeRegion – Flips and rotates a region so that x-coordinates are exchanged with y-coordinates.

ReflectRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Reflects a region through the given location.

Syntax

```
void avl::ReflectRegion
(
 const avl::Region& inRegion,
 const avl::Location& inReflectionCenter,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inReflectionCenter	const Location&		
←	outRegion	Region&		Output region

Examples

ReflectRegion *performed on the sample region.*

See Also

- MirrorRegion – Mirrors a region across vertical or horizontal axis.
- TransposeRegion – Flips and rotates a region so that x-coordinates are exchanged with y-coordinates.

ResizeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Enlarges or shrinks a region to new dimensions.

Syntax

```
void avl::ResizeRegion
(
 const avl::Region& inRegion,
 atl::Optional<int> inNewWidth,
 atl::Optional<int> inNewHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inNewWidth	Optional<int>	1 – 65535	NIL	
→	inNewHeight	Optional<int>	1 – 65535	NIL	
←	outRegion	Region&			Output region

Examples

ResizeRegion *performed on the sample region with* ***inNewWidth*** *= 200,* ***inNewHeight*** *= 100.*

See Also

- ResizeRegion_Relative – Resizes region relatively along each axis.
- DownsampleRegion – Shrinks a region by the factor of two along each axis.
- ShrinkRegionNTimes – Shrinks a region by a natural factor along each axis.
- EnlargeRegionNTimes – Enlarges a region by a natural factor.
- ResizeImage – Enlarges or shrinks an image to new dimensions.

ResizeRegion_Relative

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Resizes region relatively along each axis.

Syntax

```
void avl::ResizeRegion_Relative
(
 const avl::Region& inRegion,
 float inHorizontalScale,
 float inVerticalScale,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inHorizontalScale	float	0.0 – ∞	1.0f	
→	inVerticalScale	float	0.0 – ∞	1.0f	
←	outRegion	Region&			Output region

Examples

ResizeRegion_Relative *performed on the sample region with* ***inHorizontalScale*** *and* ***inVerticalScale*** *both set to 0,5.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Output region too big in ResizeRegion_Relative.

See Also

- ResizeRegion – Enlarges or shrinks a region to new dimensions.
- DownsampleRegion – Shrinks a region by the factor of two along each axis.
- ShrinkRegionNTimes – Shrinks a region by a natural factor along each axis.
- EnlargeRegionNTimes – Enlarges a region by a natural factor.
- ResizeImage – Enlarges or shrinks an image to new dimensions.

RotateRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Rotates a region around a specified point.

Syntax

```
void avl::RotateRegion
(
 const avl::Region& inRegion,
 atl::Optional<const avl::Point2D&> inCenter,
 float inAngle,
 const bool inInverse,
 avl::RotationSizeMode::Type inSizeMode,
 atl::Optional<int> inFrameWidth,
 atl::Optional<int> inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::CoordinateSystem2D&> outOutputAlignment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inCenter	Optional<const Point2D&>		NIL	Center of rotation
→	inAngle	float			Clockwise rotation angle
→	inInverse	const bool			Switches to counter-clockwise rotation
→	inSizeMode	RotationSizeMode::Type		Preserve	Determines whether to extent the region size to fit the rotated region.
→	inFrameWidth	Optional<int>	0 – 65535	NIL	Output region frame width, ignored when inSizeMode is set to RotationSizeMode::Fit.
→	inFrameHeight	Optional<int>	0 – 65535	NIL	Output region frame height, ignored when inSizeMode is set to RotationSizeMode::Fit.
←	outRegion	Region&			Output region
←	outOutputAlignment	Optional<CoordinateSystem2D&>		NIL	Alignment of the output region

Optional Outputs

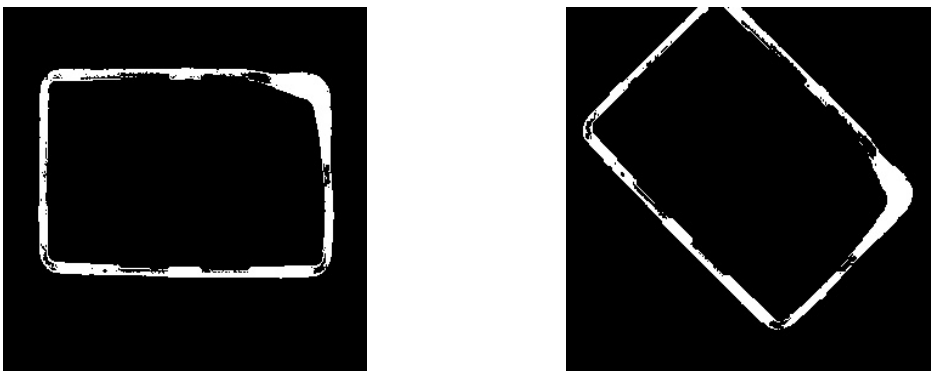
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputAlignment**.

Read more about Optional Outputs.

Description

The operation rotates a region by the **inAngle** degrees around **inCenter** point. If the **inCenter** is not provided, the rotation is conducted around the mass center of the region.

Examples



RotateRegion *performed on the sample region with* ***inAngle*** *set to 45.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input when rotation center is Nil in RotateRegion.

See Also

- TranslateRegion – Translates a region by a given number of pixels along each axis.

ShearRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes a leant region.

Syntax

```
void avl::ShearRegion
(
 const avl::Region& inRegion,
 float inShear,
 avl::Axis::Type inAxis,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inShear	float	$-\infty$ $-\infty$		The relative shift of each consecutive row or column
→	inAxis	Axis::Type			Switches between shifting rows or columns
←	outRegion	Region&			Output region

Description

The filter **ShearRegion** applies basic affine transform to each regions's pixel.

Shear affine transform when **X axis** is selected:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & inShear \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Shear affine transform when **Y axis** is selected:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ inShear & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

See Also

- ShearImage – Computes a leant image (shifts the rows).

ShrinkRegionNTimes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shrinks a region by a natural factor along each axis.

Syntax

```
void avl::ShrinkRegionNTimes
(
 const avl::Region& inRegion,
 int inNX,
 const atl::Optional<int>& inNY,
 float inThreshold,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inNX	int	1 – ∞	2	
→	inNY	const Optional<int>&	1 – ∞	NIL	
→	inThreshold	float	0.0 – 1.0	0.5f	How much of the input pixels must be present to produce output pixel. When 0 – any pixel, when 1 – all pixels.
←	outRegion	Region&			Output region

See Also

- DownsampleRegion – Shrinks a region by the factor of two along each axis.
- ResizeRegion – Enlarges or shrinks a region to new dimensions.
- ResizeRegion_Relative – Resizes region relatively along each axis.
- EnlargeRegionNTimes – Enlarges a region by a natural factor.
- ShrinkImageNTimes – Shrinks an image by a natural factor along each axis.
- ShrinkProfileNTimes – Reduces the length of a profile N-times by averaging each N consecutive elements.

TranslateRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates a region by a given number of pixels along each axis.

Syntax

```
void avl::TranslateRegion
(
 const avl::Region& inRegion,
 int inDeltaX,
 int inDeltaY,
 bool inInverse,
 atl::Optional<int> inFrameWidth,
 atl::Optional<int> inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inDeltaX	int			Horizontal shift
→	inDeltaY	int			Vertical shift
→	inInverse	bool			Negates the delta values
→	inFrameWidth	Optional<int>	0 – 65535	NIL	Output region frame width
→	inFrameHeight	Optional<int>	0 – 65535	NIL	Output region frame height
←	outRegion	Region&			Output region

Examples

TranslateRegion *performed on the sample region with* ***inDeltaX*** *and* ***inDeltaY*** *both set to 50.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in TranslateRegion.

See Also

- RotateRegion – Rotates a region around a specified point.

TransposeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Flips and rotates a region so that x-coordinates are exchanged with y-coordinates.

Syntax

```
void avl::TransposeRegion
(
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Examples

TransposeRegion *performed on the sample region.*

See Also

- MirrorRegion – Mirrors a region across vertical or horizontal axis.

TrimRegionToPolygon

Header: AVL.h
Namespace: avl
Module: FoundationPro

Removes region elements lying beyond the specified polygon.

Syntax

```
void avl::TrimRegionToPolygon
(
 const avl::Region& inRegion,
 const avl::Path& inPolygon,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inPolygon	const Path&		
←	outRegion	Region&		Output region

Errors

List of possible exceptions:

Error type	Description
DomainError	Path is not closed in TrimRegionToPolygon.

TrimRegionToRectangle

Header: AVL.h
Namespace: avl
Module: FoundationPro

Limits a region to a rectangular area.

Syntax

```
void avl::TrimRegionToRectangle
(
 const avl::Region& inRegion,
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 avl::Region& outRegion,
 atl::Optional<avl::Rectangle2D&> outAlignedRectangle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inRectangle	const Rectangle2D&		Trimming rectangle
→	inRectangleAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the rectangle to the position of the inspected object
←	outRegion	Region&		Output region
←	outAlignedRectangle	Optional<Rectangle2D&>	NIL	Input rectangle after transformation (in the region coordinates)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRectangle**.

Read more about Optional Outputs.

UncropRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Inverse of CropRegion.

Syntax

```
void avl::UncropRegion
(
 const avl::Region& inRegion,
 const avl::Box& inSelection,
 int inWidth,
 int inHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inSelection	const Box&			Box defining the range of the original cropping
→	inWidth	int	0 – 65535		Width of the uncropped region
→	inHeight	int	0 – 65535		Height of the uncropped region
←	outRegion	Region&			Output region

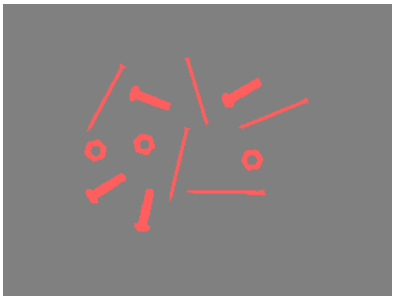
Description

The operation translates a region to original coordinates. The value of **inSelection** describes region coordinates before the cropping.

Dimensions of **outRegion** depends on **inWidth** and **inHeight**.

Examples

Images below show a typical usage of the filter **CropRegion**.



An input region.

A region after CropRegion.

Result of applying **UncropRegion** on the cropped region.

Remarks

This operation is an inversion of filter CropRegion.

See Also

- CropRegion – Creates a region from a rectangular fragment of another one.

AlignRegionToSurfaceCoordinatesFormat

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns region covering the same area for the surface with another coordinates format.

Applications: Transformation of regions defined on the image associated with the surface to image associated with another surface.

Syntax

```
void avl::AlignRegionToSurfaceCoordinatesFormat
(
 const avl::Region& inRegion,
 const avl::SurfaceCoordinatesFormat& inInputSurfaceCoordinatesFormat,
 const avl::SurfaceCoordinatesFormat& inOutputSurfaceCoordinatesFormat,
 atl::Optional<int> inFrameWidth,
 atl::Optional<int> inFrameHeight,
 avl::Region& outAlignedRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inInputSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image the input region were defined on
→	inOutputSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image the output region is defined on
→	inFrameWidth	Optional<int>	NIL	Output region's frame width
→	inFrameHeight	Optional<int>	NIL	Output region's frame height
←	outAlignedRegion	Region&		

AlignRegionToSurfaceFormat

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns region covering the same area for the surface with another format.

Applications: Transformation of regions defined on the image associated with the surface to image associated with another surface.

Syntax

```
void avl::AlignRegionToSurfaceFormat
(
 const avl::Region& inRegion,
 const avl::SurfaceCoordinatesFormat& inInputSurfaceCoordinatesFormat,
 const avl::SurfaceFormat& inOutputSurfaceFormat,
 avl::Region& outAlignedRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inInputSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image the input region were defined on
→	inOutputSurfaceFormat	const SurfaceFormat&		Format of the surface associated with the image the output region is defined on
←	outAlignedRegion	Region&		

ArrangePoint3DArray

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a surface structure from Point3D array taking into account X and Y coordinates.

Syntax

```
void avl::ArrangePoint3DArray
(
 const atl::Array<avl::Point3D>& inPoints,
 const avl::ValueLimits_f64& inXLimits,
 const double inXScale,
 const avl::ValueLimits_f64& inYLimits,
 const double inYScale,
 const avl::ValueLimits_f64& inZLimits,
 const double inZOffset,
 const double inZScale,
 avl::PlainType::Type inPointType,
 avl::SurfaceMultipointHeight::Type inMultipointHeight,
 avl::Surface& outSurface,
 atl::Optional<double&> outMinX = atl::NIL,
 atl::Optional<double&> outMinY = atl::NIL,
 avl::Region& diagSurfaceValidPointsRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			
→	inXLimits	const ValueLimits_f64&			
→	inXScale	const double	0.000001D – ∞	1.0D	
→	inYLimits	const ValueLimits_f64&			
→	inYScale	const double	0.000001D – ∞	1.0D	
→	inZLimits	const ValueLimits_f64&			
→	inZOffset	const double			
→	inZScale	const double	0.000001D – ∞	1.0D	
→	inPointType	PlainType::Type		Int16	Type of single point Z coordinate
→	inMultipointHeight	SurfaceMultipointHeight::Type		Mean	Determines the Z coordinate of a surface point created from more than one point
←	outSurface	Surface&			
←	outMinX	Optional<double&>		NIL	
←	outMinY	Optional<double&>		NIL	
🔍	diagSurfaceValidPointsRegion	Region&			Region of locations where the surface points are valid

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinX**, **outMinY**.

Read more about Optional Outputs.

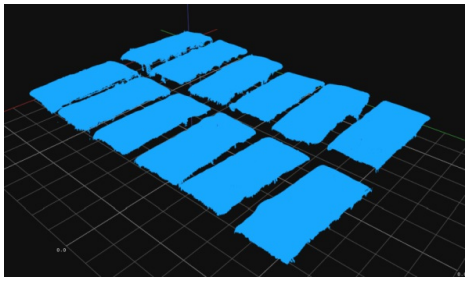
Description

The operation creates a surface object basing on the input points in 3D. The X and Y coordinates of the output surface object points are very regular, so the whole output object has neatly organized structure. Internally, the XY plane is divided into rectangular tiles with dimensions equal to **inXScale** and **inYScale**. Each tile will represent one output surface point. The point is computed as an average of all input points that are located in the corresponding tile. If none of the input points is present in a tile, the output point for such a tile is indefinite and set to the point in infinity.

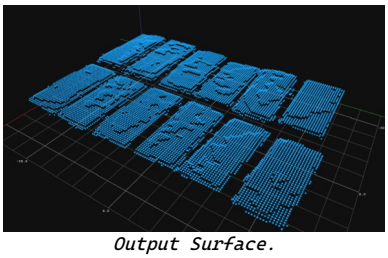
Hints

- The filter can be used to reduce the size of the input data. The higher the **inXScale** and **inYScale** values are, the smaller output surface size is.

Examples



Input Point3DArray.



Output Surface.

ArrangePoint3DArray performed on a sample surface.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array in ArrangePoint3DArray.

See Also

- ArrangePoint3DGrid – Creates a surface structure from Point3DGrid taking into account X and Y coordinates.

ArrangePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a surface structure from Point3DGrid taking into account X and Y coordinates.

Syntax

```
void avl::ArrangePoint3DGrid
(
 const avl::Point3DGrid& inPoint3DGrid,
 const avl::ValueLimits_f64& inXLimits,
 const double inXScale,
 const avl::ValueLimits_f64& inYLimits,
 const double inYScale,
 const avl::ValueLimits_f64& inZLimits,
 const double inZOffset,
 const double inZScale,
 avl::PlainType::Type inPointType,
 avl::SurfaceMultipointHeight::Type inMultipointHeight,
 avl::Surface& outSurface,
 atl::Optional<double&> outMinX = atl::NIL,
 atl::Optional<double&> outMinY = atl::NIL,
 avl::Region& diagSurfaceValidPointsRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid	const Point3DGrid&			
→	inXLimits	const ValueLimits_f64&			
→	inXScale	const double	0.000001D – ∞	1.0D	
→	inYLimits	const ValueLimits_f64&			
→	inYScale	const double	0.000001D – ∞	1.0D	
→	inZLimits	const ValueLimits_f64&			
→	inZOffset	const double			
→	inZScale	const double	0.000001D – ∞	1.0D	
→	inPointType	PlainType::Type		Int16	Type of single point Z coordinate
→	inMultipointHeight	SurfaceMultipointHeight::Type		Mean	Determines the Z coordinate of a surface point created from more than one point
←	outSurface	Surface&			
←	outMinX	Optional<double&>		NIL	
←	outMinY	Optional<double&>		NIL	
🔍	diagSurfaceValidPointsRegion	Region&			Region of locations where the surface points are valid

ConvertCoordinateSystem2DTo3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Converts a coordinate system connected with the surface image to a coordinate system connected with the surface.

Syntax

```
void avl::ConvertCoordinateSystem2DTo3D
(
 const avl::CoordinateSystem2D& inCoordinateSystem,
 const avl::SurfaceFormat& inSurfaceFormat,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inCoordinateSystem	const CoordinateSystem2D&		Coordinate system connected with the surface image
→	inSurfaceFormat	const SurfaceFormat&		Format of the surface
←	outCoordinateSystem	CoordinateSystem2D&		Coordinate system connected with the surface

ConvertSurfaceType

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Changes the point Z coordinate type.

Syntax

```
void avl::ConvertSurfaceType
(
 const avl::Surface& inSurface,
 avl::PlainType::Type inNewPointType,
 atl::Optional<double> inNewZOffset,
 atl::Optional<double> inNewZScale,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inNewPointType	PlainType::Type		Point Z coordinate type of the output surface
→	inNewZOffset	Optional<double>	NIL	Offset along Z axis in output surface
→	inNewZScale	Optional<double>	NIL	Scale along Z axis in output surface
←	outSurface	Surface&		Surface with changed internal surface type

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

CreateFlatSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a uniform surface.

Syntax

```
void avl::CreateFlatSurface
(
 const int inWidth,
 const int inHeight,
 const avl::PlainType::Type& inPointType,
 const double inXOffset,
 const double inXScale,
 const double inYOffset,
 const double inYScale,
 const double inZOffset,
 const double inZScale,
 atl::Optional<double> inZ,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inWidth	const int	1 – 65535	320	Width of the created surface
→	inHeight	const int	1 – 65535	240	Height of the created surface
→	inPointType	const PlainType::Type&		Int16	Type of single point Z coordinate
→	inXOffset	const double		0.0D	
→	inXScale	const double	0.001D – ∞	1.0D	
→	inYOffset	const double		0.0D	
→	inYScale	const double	0.001D – ∞	1.0D	
→	inZOffset	const double		0.0D	
→	inZScale	const double	0.001D – ∞	1.0D	
→	inZ	Optional<double>		0.0D	Z coordinate of all points of the created surface
←	outSurface	Surface&			

CreateSurfaceFromImage

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a Surface structure from coordinates encoded in pixels of an image.

Applications: Creating a Surface structure out of an image obtained from a 3D camera or other external sources that encodes 3D surface as pixel components of 2D image.

Syntax

```
void avl::CreateSurfaceFromImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::PointCloudCoordinateTransform& inXCoordinateTransform,
 const avl::PointCloudCoordinateTransform& inYCoordinateTransform,
 const avl::PointCloudCoordinateTransform& inZCoordinateTransform,
 const avl::OutputSurfaceFormat& inCreatedSurfaceFormat,
 avl::Surface& outSurface,
 avl::Region& diagSurfaceValidPointsRegion,
 avl::Point3DGrid& diagPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	const Image&		Source image with per pixel encoded XYZ coordinates
➡	inRoi	Optional<const Region&>	NIL	Region determining valid points in resulting point grid
➡	inXCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 0 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the X coordinate
➡	inYCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 1 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the Y coordinate
➡	inZCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 2 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the Z coordinate
➡	inCreatedSurfaceFormat	const OutputSurfaceFormat&	OutputSurfaceFormat (XScale: 1.000000D YScale: 1.000000D ZScale: 1.000000D ZOffset: 0.000000D PointType: UInt16 MultipointHeight: Mean)	Parameters for arranging points into Surface
⬅	outSurface	Surface&		
🔍	diagSurfaceValidPointsRegion	Region&		Region of locations where the surface points are valid
🔍	diagPoint3DGrid	Point3DGrid&		Points decoded before arranging them into Surface

Description

The operation creates a point cloud object based on the input point image. It can be thought of as a combination of two operations: CreatePoint3DGridFromImage and ArrangePoint3DArray.

See Also

- ArrangePoint3DArray – Creates a surface structure from Point3D array taking into account X and Y coordinates.
- CreatePoint3DGridFromImage – Creates a Point3DGrid structure from coordinates encoded in pixels of image.

GetSurfaceElement_Interpolated

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns an interpolated single point of a surface given its surface grid coordinates.

Syntax

```
void avl::GetSurfaceElement_Interpolated
(
 const avl::Surface& inSurface,
 const avl::Point2D& inPoint,
 int inInterpolationRadius,
 avl::Point3D& outPoint
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inPoint	const Point2D&			Surface grid coordinates of the input point
→	inInterpolationRadius	int	0 – 65535	0	Radius of vicinity being taken into account to interpolate not existing point
←	outPoint	Point3D&			Output point

GetSurfacePath

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns a path consisting of interpolated single points of a surface given their surface grid coordinates.

Syntax

```
void avl::GetSurfacePath
(
 const avl::Surface& inSurface,
 const avl::Path& inPath,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inPath	const Path&		Surface grid coordinates of the input path points
←	outPath	Path&		Output path in surface coordinates

ImageBoxToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image box.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageBoxToSurfaceCoordinates
(
 const avl::Box& inImageBox,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Box& outSurfaceBox,
 atl::Optional<avl::Box3D&> outSurfaceBox3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageBox	const Box&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceBox	Box&		
←	outSurfaceBox3D	Optional<Box3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceBox3D**.

Read more about Optional Outputs.

ImageCircleToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image circle.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageCircleToSurfaceCoordinates
(
 const avl::Circle2D& inImageCircle,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Circle2D& outSurfaceCircle,
 atl::Optional<avl::Circle3D&> outSurfaceCircle3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageCircle	const Circle2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceCircle	Circle2D&		
←	outSurfaceCircle3D	Optional<Circle3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceCircle3D**.

Read more about Optional Outputs.

ImageCoordinateSystemToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image coordinate system.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageCoordinateSystemToSurfaceCoordinates
(
 const avl::CoordinateSystem2D& inImageCoordinateSystem,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::CoordinateSystem2D& outSurfaceCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inImageCoordinateSystem	const CoordinateSystem2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceCoordinateSystem	CoordinateSystem2D&		

ImageLineToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image line.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageLineToSurfaceCoordinates
(
 const avl::Line2D& inImageLine,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Line2D& outSurfaceLine,
 atl::Optional<avl::Line3D&> outSurfaceLine3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageLine	const Line2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceLine	Line2D&		
←	outSurfaceLine3D	Optional<Line3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceLine3D**.

Read more about Optional Outputs.

ImagePathsToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image paths.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImagePathsToSurfaceCoordinates
(
 const atl::Array<avl::Path>& inImagePaths,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Path>& outSurfacePaths
)
```

Parameters

	Name	Type	Default	Description
→	inImagePaths	const Array<Path>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfacePaths	Array<Path>&		

ImagePathToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image path.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImagePathToSurfaceCoordinates
(
 const avl::Path& inImagePath,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Path& outSurfacePath
)
```

Parameters

	Name	Type	Default	Description
→	inImagePath	const Path&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfacePath	Path&		

ImagePointsToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image points.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImagePointsToSurfaceCoordinates
(
 const atl::Array<avl::Point2D>& inImagePoints,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Point2D>& outSurfacePoints
)
```

Parameters

	Name	Type	Default	Description
→	inImagePoints	const Array<Point2D>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfacePoints	Array<Point2D>&		

ImagePointToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image point.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImagePointToSurfaceCoordinates
(
 const avl::Point2D& inImagePoint,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Point2D& outSurfacePoint,
 atl::Optional<avl::Point3D&> outSurfacePoint3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImagePoint	const Point2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfacePoint	Point2D&		
←	outSurfacePoint3D	Optional<Point3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfacePoint3D**.

Read more about Optional Outputs.

ImageSegmentsToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image segments.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageSegmentsToSurfaceCoordinates
(
 const atl::Array<avl::Segment2D>& inImageSegments,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Segment2D>& outSurfaceSegments
)
```

Parameters

	Name	Type	Default	Description
→	inImageSegments	const Array<Segment2D>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceSegments	Array<Segment2D>&		

ImageSegmentToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image segment.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageSegmentToSurfaceCoordinates
(
 const avl::Segment2D& inImageSegment,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Segment2D& outSurfaceSegment,
 atl::Optional<avl::Segment3D&> outSurfaceSegment3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageSegment	const Segment2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceSegment	Segment2D&		
←	outSurfaceSegment3D	Optional<Segment3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceSegment3D**.

Read more about Optional Outputs.

ImageVectorToSurfaceCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface coordinates of image vector.

Applications: Transformation of results found on the image associated with the surface to the surface coordinates.

Syntax

```
void avl::ImageVectorToSurfaceCoordinates
(
 const avl::Vector2D& inImageVector,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Vector2D& outSurfaceVector,
 atl::Optional<avl::Vector3D&> outSurfaceVector3D = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageVector	const Vector2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outSurfaceVector	Vector2D&		
←	outSurfaceVector3D	Optional<Vector3D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceVector3D**.

Read more about Optional Outputs.

ProjectPathOntoSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns a path consisting of interpolated single points of a surface given their coordinates in surface coordinate system.

Syntax

```
void avl::ProjectPathOntoSurface
(
 const avl::Surface& inSurface,
 const avl::Path& inPath,
 avl::Path& outSurfaceGridPath
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inPath	const Path&		Coordinates of the input path points in surface coordinate system
←	outSurfaceGridPath	Path&		Output path in surface grid coordinate system

ProjectPointOntoSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns an interpolated single point of a surface given its coordinates in surface coordinate system.

Syntax

```
void avl::ProjectPointOntoSurface
(
 const avl::Surface& inSurface,
 const avl::Point2D& inPoint,
 int inInterpolationRadius,
 atl::Optional<avl::Point3D&> outSurfaceRealPoint = atl::NIL,
 atl::Optional<avl::Point2D&> outSurfaceGridPoint = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inPoint	const Point2D&			Coordinates of the input point in surface coordinate system
→	inInterpolationRadius	int	0 – 65535	0	Radius of vicinity being taken into account to interpolate not existing point
←	outSurfaceRealPoint	Optional<Point3D&>		NIL	Output point in surface coordinate system
←	outSurfaceGridPoint	Optional<Point2D&>		NIL	Output point in surface grid coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceRealPoint**, **outSurfaceGridPoint**.

Read more about Optional Outputs.

ProjectSurfaceOntoAxesPlane

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Projects a surface onto one of three axes planes.

Syntax

```
void avl::ProjectSurfaceOntoAxesPlane
(
 const avl::Surface& inSurface,
 avl::PlaneType::Type inAxesPlaneType,
 atl::Optional<double> inOutputXScale,
 const avl::ValueLimits_f64& inOutputXLimits,
 atl::Optional<double> inOutputYScale,
 const avl::ValueLimits_f64& inOutputYLimits,
 const double inOutputZOffset,
 atl::Optional<double> inOutputZScale,
 const avl::ValueLimits_f64& inOutputZLimits,
 avl::PlainType::Type inPointType,
 avl::SurfaceMultipointHeight::Type inMultipointHeight,
 avl::Surface& outSurface,
 atl::Optional<double&> outMinOutputX = atl::NIL,
 atl::Optional<double&> outMinOutputY = atl::NIL,
 avl::Region& diagSurfaceValidPointsRegion
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			
➡	inAxesPlaneType	PlaneType::Type		XZ	
➡	inOutputXScale	Optional<double>	0.000001D – ∞	1.0D	
➡	inOutputXLimits	const ValueLimits_f64&			
➡	inOutputYScale	Optional<double>	0.000001D – ∞	1.0D	
➡	inOutputYLimits	const ValueLimits_f64&			
➡	inOutputZOffset	const double			
➡	inOutputZScale	Optional<double>	0.000001D – ∞	1.0D	
➡	inOutputZLimits	const ValueLimits_f64&			
➡	inPointType	PlainType::Type		Int16	Type of single point Z coordinate
➡	inMultipointHeight	SurfaceMultipointHeight::Type		Mean	Determines the Z coordinate of a surface point created from more than one point
⬅	outSurface	Surface&			
⬅	outMinOutputX	Optional<double&>		NIL	
⬅	outMinOutputY	Optional<double&>		NIL	
🔍	diagSurfaceValidPointsRegion	Region&			Region of locations where the surface points are valid

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinOutputX**, **outMinOutputY**.

Read more about Optional Outputs.

ResamplePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a surface structure from Point3DGrid taking into account X and Y coordinates and trying to preserve continuity of the surface.

Syntax

```
void avl::ResamplePoint3DGrid
(
 const avl::Point3DGrid& inPoint3DGrid,
 const avl::ValueLimits_f64& inXLimits,
 const avl::ValueLimits_f64& inYLimits,
 const double inZOffset,
 const double inZScale,
 avl::PlainType::Type inPointType,
 avl::SurfaceMultipointHeight::Type inMultipointHeight,
 avl::Surface& outSurface,
 atl::Optional<double&> outMinX = atl::NIL,
 atl::Optional<double&> outMinY = atl::NIL,
 avl::Region& diagSurfaceValidPointsRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid	const Point3DGrid&			
→	inXLimits	const ValueLimits_f64&			
→	inYLimits	const ValueLimits_f64&			
→	inZOffset	const double			
→	inZScale	const double	0.000001D – ∞	1.0D	
→	inPointType	PlainType::Type		Int16	Type of single point Z coordinate
→	inMultipointHeight	SurfaceMultipointHeight::Type		Mean	Determines the Z coordinate of a surface point created from more than one point
←	outSurface	Surface&			
←	outMinX	Optional<double&>		NIL	
←	outMinY	Optional<double&>		NIL	
🔍	diagSurfaceValidPointsRegion	Region&			Region of locations where the surface points are valid

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinX**, **outMinY**.

Read more about Optional Outputs.

Remarks

- This filter is kept only as a legacy feature and its use in new applications is discouraged as ArrangePoint3DGrid offers the same functionalities with higher flexibility when it comes to scale setting (which in turn is fixed at 2.5 for both the X and Y axis in the case of ResamplePoint3DGrid).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array in ResamplePoint3DGrid.
DomainError	Incorrect coordinate limits in ResamplePoint3DGrid.
DomainError	Surface dimensions too big in ResamplePoint3DGrid.

SkipEmptySurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

If the input Surface has at least one point defined, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty surfaces, e.g. just before the FitPlaneToSurface filter is to be invoked.

Syntax

```
void avl::SkipEmptySurface
(
 const avl::Surface& inSurface,
 atl::Conditional<avl::Surface>& outNotEmptySurface,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
←	outNotEmptySurface	Conditional<Surface>&		A copy of the input surface, if it is not empty, or Nil otherwise
←	outIsNotEmpty	bool&		Indication if the input surface is not empty

SkipEmptySurfaceRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

If the input surface contains at least one valid point in a given region, then the region is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by regions with no valid point, e.g. just before the SurfaceMassCenter filter is to be invoked.

Syntax

```
void avl::SkipEmptySurfaceRegion
(
 const avl::Surface& inSurface,
 const avl::Region& inRegion,
 atl::Conditional<avl::Region>& outNotEmptySurfaceRegion,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		
→	inRegion	const Region&		Input region
←	outNotEmptySurfaceRegion	Conditional<Region>&		
←	outIsNotEmpty	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Input region frame exceeds the input surface frame in SkipEmptySurfaceRegion.

SurfaceBoxToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface box.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceBoxToImageCoordinates
(
 const avl::Box3D& inSurfaceBox,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Box& outImageBox,
 atl::Optional<avl::Rectangle2D&> outImageRectangle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceBox	const Box3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageBox	Box&		
←	outImageRectangle	Optional<Rectangle2D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outImageRectangle**.

Read more about Optional Outputs.

SurfaceBoxToRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface region covered by surface box.

Applications: Transformation of objects defined in the surface coordinate system to the associated surface region.

Syntax

```
void avl::SurfaceBoxToRegion
(
 const avl::Box3D& inSurfaceBox,
 const avl::SurfaceFormat& inSurfaceFormat,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceBox	const Box3D&		
→	inSurfaceFormat	const SurfaceFormat&		Surface format for which the output region will be defined
←	outRegion	Region&		Output region

SurfaceCircleToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface circle.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceCircleToImageCoordinates
(
 const avl::Circle3D& inSurfaceCircle,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Circle2D& outImageCircle
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceCircle	const Circle3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageCircle	Circle2D&		

SurfaceCircleToRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface region covered by surface circle.

Applications: Transformation of objects defined in the surface coordinate system to the associated surface region.

Syntax

```
void avl::SurfaceCircleToRegion
(
 const avl::Circle3D& inSurfaceCircle,
 const avl::SurfaceFormat& inSurfaceFormat,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceCircle	const Circle3D&		
→	inSurfaceFormat	const SurfaceFormat&		Surface format for which the output region will be defined
←	outRegion	Region&		Output region

SurfaceCoordinateSystemToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface coordinate system.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceCoordinateSystemToImageCoordinates
(
 const avl::CoordinateSystem2D& inSurfaceCoordinateSystem,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::CoordinateSystem2D& outImageCoordinateSystem
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceCoordinateSystem	const CoordinateSystem2D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageCoordinateSystem	CoordinateSystem2D&		

SurfaceLineToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface line.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceLineToImageCoordinates
(
 const avl::Line3D& inSurfaceLine,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Line2D& outImageLine
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceLine	const Line3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageLine	Line2D&		

SurfacePathsToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface paths.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfacePathsToImageCoordinates
(
 const atl::Array<avl::Path>& inSurfacePaths,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Path>& outImagePaths
)
```

Parameters

	Name	Type	Default	Description
→	inSurfacePaths	const Array<Path>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImagePaths	Array<Path>&		

SurfacePathToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface path.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfacePathToImageCoordinates
(
 const avl::Path& inSurfacePath,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Path& outImagePath
)
```

Parameters

	Name	Type	Default	Description
→	inSurfacePath	const Path&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImagePath	Path&		

SurfacePathToRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface region covered by surface path.

Applications: Transformation of objects defined in the surface coordinate system to the associated surface region.

Syntax

```
void avl::SurfacePathToRegion
(
 const avl::Path& inSurfacePath,
 const avl::SurfaceFormat& inSurfaceFormat,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inSurfacePath	const Path&		
→	inSurfaceFormat	const SurfaceFormat&		Surface format for which the output region will be defined
←	outRegion	Region&		Output region

SurfacePointsToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface points.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfacePointsToImageCoordinates
(
 const atl::Array<avl::Point3D>& inSurfacePoints,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Point2D>& outImagePoints
)
```

Parameters

	Name	Type	Default	Description
→	inSurfacePoints	const Array<Point3D>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImagePoints	Array<Point2D>&		

SurfacePointToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface point.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfacePointToImageCoordinates
(
 const avl::Point3D& inSurfacePoint,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Point2D& outImagePoint
)
```

Parameters

	Name	Type	Default	Description
→	inSurfacePoint	const Point3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImagePoint	Point2D&		

SurfaceSegmentsToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface segments.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceSegmentsToImageCoordinates
(
 const atl::Array<avl::Segment3D>& inSurfaceSegments,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 atl::Array<avl::Segment2D>& outImageSegments
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceSegments	const Array<Segment3D>&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageSegments	Array<Segment2D>&		

SurfaceSegmentToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface segment.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceSegmentToImageCoordinates
(
 const avl::Segment3D& inSurfaceSegment,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Segment2D& outImageSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceSegment	const Segment3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageSegment	Segment2D&		

SurfaceVectorToImageCoordinates

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the associated image coordinates of surface vector.

Applications: Transformation of objects defined in the surface coordinate system to the associated image coordinate system.

Syntax

```
void avl::SurfaceVectorToImageCoordinates
(
 const avl::Vector3D& inSurfaceVector,
 const avl::SurfaceCoordinatesFormat& inSurfaceCoordinatesFormat,
 avl::Vector2D& outImageVector
)
```

Parameters

	Name	Type	Default	Description
→	inSurfaceVector	const Vector3D&		
→	inSurfaceCoordinatesFormat	const SurfaceCoordinatesFormat&		Offsets and scales on X and Y axes of the surface associated with the image objects were found on
←	outImageVector	Vector2D&		

TestSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns a sample 3D surface.

Syntax

```
void avl::TestSurface
(
 TestSurfaceState& ioState,
 const avl::PlainType::Type& inPointType,
 const float inDensity,
 const float inScaleX,
 const float inScaleY,
 const float inScaleZ,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	TestSurfaceState&			Object used to maintain state of the function.
→	inPointType	const PlainType::Type&		Int16	Type of single point Z coordinate
→	inDensity	const float	1.0 – 20.0	4.0f	Density of points along each axis over a unit of 10
→	inScaleX	const float	0.001 – ∞	1.0f	Scaling of output object on X axis
→	inScaleY	const float	0.001 – ∞	1.0f	Scaling of output object on Y axis
→	inScaleZ	const float	0.001 – ∞	1.0f	Scaling of output object on Z axis
←	outSurface	Surface&			Output object

30. Shape Region Basics

Table of content:

- AlignShapeRegion
- CreateShapeRegionRegion
- PathToShapeRegion
- ShapeRegionToRegion

AlignShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Aligns a shape region to a coordinate system.

Syntax

```
void avl::AlignShapeRegion
(
 const avl::ShapeRegion& inShapeRegion,
 const avl::CoordinateSystem2D& inShapeRegionAlignment,
 bool inInverse,
 atl::Optional<int> inFrameWidth,
 atl::Optional<int> inFrameHeight,
 avl::ShapeRegion& outAlignedShapeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inShapeRegion	const ShapeRegion&			
→	inShapeRegionAlignment	const CoordinateSystem2D&			Coordinate system to align to
→	inInverse	bool			Switches to the inverse transform
→	inFrameWidth	Optional<int>	0 – 65535	NIL	Width of the created region's frame
→	inFrameHeight	Optional<int>	0 – 65535	NIL	Height of the created region's frame
←	outAlignedShapeRegion	ShapeRegion&			

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inShapeRegion** and **outAlignedShapeRegion**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid ShapeRegion in AlignShapeRegion.

CreateShapeRegionRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a region corresponding to the given shape region.

Syntax

```
void avl::CreateShapeRegionRegion
(
 const avl::ShapeRegion& inShapeRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inShapeRegionAlignment,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::ShapeRegion&> outAlignedShapeRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inShapeRegion	const ShapeRegion&			
→	inShapeRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the shape region to the position of the inspected object
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedShapeRegion	Optional<ShapeRegion&>		NIL	Transformed input shape region

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedShapeRegion**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid ShapeRegion in CreateShapeRegionRegion.

PathToShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a closed path to a shape region.

Syntax

```
void avl::PathToShapeRegion
(
 const avl::Path& inPath,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outShapeRegion	ShapeRegion&		

ShapeRegionToRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a shape region to a region with an automatically computed frame.

Syntax

```
void avl::ShapeRegionToRegion
(
 const avl::ShapeRegion& inShapeRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inShapeRegion	const ShapeRegion&		
←	outRegion	Region&		Output region

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid ShapeRegion in ShapeRegionToRegion.

31. Geometry 3D Fitting

Table of content:

- FitSegmentToPoints3D
- FitSegmentToPoints3D_LTE
- FitSegmentToPoints3D_RANSAC

AnalyzePoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Analyzes the steps in X and Y directions of a point 3D grid.

Syntax

```
void avl::AnalyzePoint3DGrid
(
 const avl::Point3DGrid& inPointGrid,
 avl::Point3DGridType::Type inPointGridType,
 const avl::ValueLimits& inXLimits,
 const avl::ValueLimits& inYLimits,
 const avl::ValueLimits& inZLimits,
 const float inEpsilonX,
 const float inEpsilonY,
 const float inCoverage,
 double& outScaleX,
 double& outOffsetX,
 double& outScaleY,
 double& outOffsetY
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointGrid	const Point3DGrid&			
→	inPointGridType	Point3DGridType::Type			
→	inXLimits	const ValueLimits&			Limits for the X coordinate
→	inYLimits	const ValueLimits&			Limits for the Y coordinate
→	inZLimits	const ValueLimits&			Limits for the Z coordinate
→	inEpsilonX	const float	0.0 – ∞	0.0f	Maximum possible error in the X direction
→	inEpsilonY	const float	0.0 – ∞		Maximum possible error in the Y direction
→	inCoverage	const float	0.0 – 1.0	0.3f	Percentage of points that should be taken into account
←	outScaleX	double&			
←	outOffsetX	double&			
←	outScaleY	double&			
←	outOffsetY	double&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported inPointGridType in AnalyzePoint3DGrid.

FitCircle3DToHole

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Fits a circle to a hole in a plane.

Syntax

```
void avl::FitCircle3DToHole
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 avl::MEstimator::Type inPlaneOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 avl::CircleFittingMethod::Type inCircleFittingMethod,
 atl::Optional<avl::MEstimator::Type> inCircleOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle3D,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inPointGrid	const Point3DGrid&			
➡	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
➡	inPlaneOutlierSuppression	MEstimator::Type			
➡	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers

⬅	outSquaredDistanceSum	Optional<float&>		NIL	Sum of squared distances of the input points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**, **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

FitCircleToPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a circle using selected outliers suppression method.

Syntax

```
void avl::FitCircleToPoints3D
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Optional<const avl::Plane3D&> inPlane,
 atl::Conditional<avl::Circle3D>& outCircle,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
→	inFittingMethod	CircleFittingMethod::Type		
→	inOutlierSuppression	Optional<MEstimator::Type>	NIL	
→	inPlane	Optional<const Plane3D&>	NIL	
←	outCircle	Conditional<Circle3D>&		Fitted circle or nothing if method failed to converge,
←	outInliers	Optional<Array<Point3D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array on input in FitCircleToPoints3D.

FitLineToPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a line using the Least Squares method.

Syntax

```
void avl::FitLineToPoints3D
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::Line3D& outLine,
 atl::Optional<float&> outError = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
←	outLine	Line3D&		
←	outError	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outError**.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array in FitLineToPoints3D.

FitLineToPoints3D_LTE

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a line using Least Trimmed Error algorithm.

Syntax

```
void avl::FitLineToPoints3D_LTE
(
 const atl::Array<avl::Point3D>& inPoints,
 int inSeedSubsetSize,
 atl::Optional<int> inEvalSubsetSize,
 avl::Line3D& outLine,
 atl::Optional<atl::Array<avl::Point3D>&> outLTInliers = atl::NIL,
 atl::Optional<float&> outLTError = atl::NIL,
 int& diagIterationCount = atl::Dummy<int>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			
→	inSeedSubsetSize	int	2 – 10	3	Number of points in one combination for getting a sample line
→	inEvalSubsetSize	Optional<int>	3 – ∞	NIL	Number of closest points used for evaluation of a sample line, or Auto if seed points are to be used
←	outLine	Line3D&			Fitted line
←	outLTInliers	Optional<Array<Point3D>&>		NIL	Inlying points of the best LTE line
←	outLTError	Optional<float&>		NIL	The Least Trimmed Error
🔍	diagIterationCount	int&			Number of combinations considered

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLTInliers**, **outLTError**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inPoints array in FitLineToPoints3D_LTE.

FitLineToPoints3D_M

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a line using selected M-estimator for outlier suppression.

Applications: Finding a locally optimal line in 3D. Good enough when the number of outliers is small.

Syntax

```
void avl::FitLineToPoints3D_M
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Line3D&> inInitialLine,
 avl::Line3D& outLine,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			
→	inOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialLine	Optional<const Line3D&>		NIL	Initial approximation (if available)
←	outLine	Line3D&			
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the computed line

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array on input in FitLineToPoints3D_M.

FitLineToPoints3D_RANSAC

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a line using a RANSAC algorithm.

Syntax

```
void avl::FitLineToPoints3D_RANSAC
(
 const atl::Array<avl::Point3D>& inPoints,
 atl::Optional<int> inMaxOutlierCount,
 const float inMaxInlierDistance,
 atl::Optional<int> inIterationCount,
 atl::Conditional<avl::Line3D>& outLine
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			
→	inMaxOutlierCount	Optional<int>	0 – ∞	NIL	Determines how many outlier points can be present to end the search
→	inMaxInlierDistance	const float	0.0 – ∞	3.0f	Distance from the output line for a point to be considered an inlier
→	inIterationCount	Optional<int>	1 – ∞	42	Number of iterations; Auto means that all point pairs will be used
←	outLine	Conditional<Line3D>&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inPoints array in FitLineToPoints3D_RANSAC.

FitPlaneToPoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points with a plane using the Least Squares method.

Syntax

```
void avl::FitPlaneToPoints
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
←	outPlane	Plane3D&		Fitted plane
←	outDistances	Optional<Array<float>&>	NIL	Distances of the input points to a resulting plane
←	outSignedDistanceSum	Optional<float&>	NIL	Sum of signed distances of the input points to a resulting plane
←	outDistanceSum	Optional<float&>	NIL	Sum of distances of the input points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>	NIL	Squared distances of the input points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>	NIL	Sum of squared distances of the input points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

FitPlaneToPoints_M

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points with a plane using selected M-estimator for outlier suppression.

Applications: Finding a locally optimal plane. Good enough when the number of outliers is small.

Syntax

```
void avl::FitPlaneToPoints_M
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			
→	inOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialPlane	Optional<const Plane3D&>		NIL	Initial approximation (if available)
←	outPlane	Plane3D&

FitSegmentToPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points in 3D with a segment using selected outliers suppression method.

Syntax

```
void avl::FitSegmentToPoints3D
(
 const atl::Array<avl::Point3D>& inPoints,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Segment3D>& outSegment,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
→	inOutlierSuppression	Optional<MEstimator::Type>	Tukey	
←	outSegment	Conditional<Segment3D>&		Fitted segment or nothing if method failed to converge
←	outInliers	Optional<Array<Point3D>&>	NIL	Points matching the computed segment

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**.

32. Geometry 2D Angle Metrics

Table of content:

- AngleBetweenDirections
- AngleBetweenLines
- AngleBetweenSegments
- AngleBetweenThreePoints
- AngleBetweenVectors
- NormalizeAngle

AngleBetweenDirections

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the rotation angle from first to second direction.

Syntax

```
void avl::AngleBetweenDirections
(
 float inDirection1,
 float inDirection2,
 atl::Optional<avl::RotationDirection::Type> inRotationDirection,
 avl::AngleRange::Type inAngleRange,
 atl::Optional<float&> outAbsoluteAngle = atl::NIL,
 atl::Optional<float&> outDirectedAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inDirection1	float		Start direction
→	inDirection2	float		Target direction
→	inRotationDirection	Optional<RotationDirection::Type>	NIL	Clockwise, counter-clockwise or automatic (by smaller angle)
→	inAngleRange	AngleRange::Type	_0_180	Switches between ranges <0; 90), <0; 180) and <0; 360)
←	outAbsoluteAngle	Optional<float&>	NIL	Angle value used for measurements <0; 360>
←	outDirectedAngle	Optional<float&>	NIL	Angle value used for clockwise transformations <-360; 360>

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAbsoluteAngle**, **outDirectedAngle**.

Read more about Optional Outputs.

Description

Direction is a number in the range of <0, 180) or <0, 360). This is controlled with the **inAngleRange** input. The angle is computed from first to second direction clockwise or counter-clockwise. If the rotation direction is not specified, chosen is the one that produces smaller absolute angle.

- AngleBetweenLines – Measures the smaller and the larger angle between two lines.

AngleBetweenLines

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the smaller and the larger angle between two lines.

Syntax

```
void avl::AngleBetweenLines
(
 const avl::Line2D& inLine1,
 const avl::Line2D& inLine2,
 atl::Optional<float&> outSmallerAngle = atl::NIL,
 atl::Optional<float&> outLargerAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inLine1	const Line2D&		
→	inLine2	const Line2D&		
←	outSmallerAngle	Optional<float&>	NIL	
←	outLargerAngle	Optional<float&>	NIL	

Optional Outputs

- AngleBetweenSegments – Measures the angle between two segments with one of four possible metrics.

AngleBetweenSegments

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the angle between two segments with one of four possible metrics.

Syntax

```
void avl::AngleBetweenSegments
(
 const avl::Segment2D& inSegment1,
 const avl::Segment2D& inSegment2,
 avl::AngleMetric::Type inAngleMetric,
 bool inAutodetectOrientation,
 atl::Optional<float&> outAbsoluteAngle = atl::NIL,
 atl::Optional<float&> outDirectedAngle = atl::NIL,
 atl::Optional<avl::Arc2D&> outArc = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSegment1	const Segment2D&		First segment
→	inSegment2	const Segment2D&		Second segment
→	inAngleMetric	AngleMetric::Type		Chooses one of four possible ways of measuring the angle
→	inAutodetectOrientation	bool	True	Autodetects orientation of the segments assuming that these are two consecutive sides of a polygon
←	outAbsoluteAngle	Optional<float&>	NIL	Angle value used for measurements <0; 360>
←	outDirectedAngle	Optional<float&>	NIL	Angle value used for clockwise transformations <-360; 360>
←	outArc	Optional<Arc2D&>	NIL	Angle visualization object

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAbsoluteAngle**, **outDirectedAngle**, **outArc**.

Read more about Optional Outputs.

Description

Angle between segments can be interpreted in two different ways:

1. Segments as vectors - the angle is measured from the first to the second vector clockwise or counter-clockwise.
2. Segments as consecutive sides of a polygon - the angle is measured from the first to the second side clockwise or counter-clockwise.

The method that is appropriate in a particular case can be chosen with the **inAngleMetric** input. Possible values are:

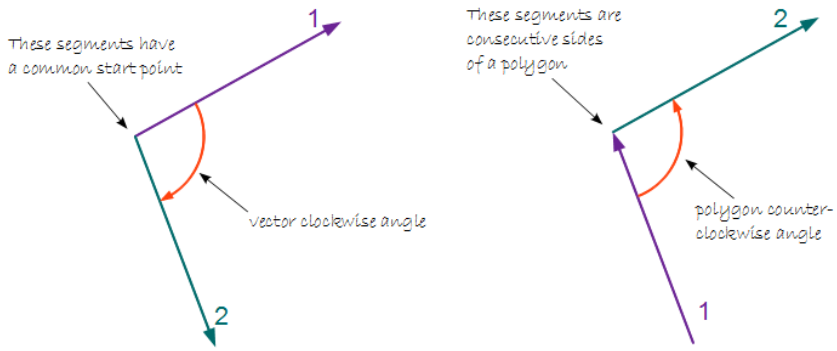
- VectorClockwiseAngle
- VectorCounterClockwiseAngle
- PolygonClockwiseAngle
- PolygonCounterClockwiseAngle

Segment Orientation

We do not usually care about orientation of a segment. However, when measuring angles, this information is important. In the most typical application, which is measuring an angle between two consecutive sides of a polygon, orientation of the segments is used together with **inAngleMetric** to determine the corner point and the side of the polygon (inside or outside). This information can also be obtained automatically by considering the intersection point between lines containing the segments. The **inAutodetectOrientation** parameter is there for that purpose. However, keep in mind that this method may produce unexpected results when the segments are parallel or nearly parallel.

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an empty segment is given on input.

Examples



Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported angle metric in AngleBetweenSegments.

See Also

- AngleBetweenThreePoints – Measures the angle defined by three consecutive points.
- AngleBetweenVectors – Measures the angle between two vectors.

AngleBetweenThreePoints

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the angle defined by three consecutive points.

Syntax

```
void avl::AngleBetweenThreePoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 const avl::Point2D& inPoint3,
 avl::RotationDirection::Type inRotationDirection,
 atl::Optional<float&> outAbsoluteAngle = atl::NIL,
 atl::Optional<float&> outDirectedAngle = atl::NIL,
 atl::Optional<avl::Arc2D&> outArc = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		A point on one arm of an angle
→	inPoint2	const Point2D&		The middle point
→	inPoint3	const Point2D&		A point on another arm of the angle
→	inRotationDirection	RotationDirection::Type		Chooses one of two ways of measuring the angle
←	outAbsoluteAngle	Optional<float&>	NIL	Angle value used for measurements <0; 360>
←	outDirectedAngle	Optional<float&>	NIL	Angle value used for clockwise transformations <-360; 360>
←	outArc	Optional<Arc2D&>	NIL	Angle visualization object

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAbsoluteAngle**, **outDirectedAngle**, **outArc**.

Read more about Optional Outputs.

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when some two of the input points are almost equal.

AngleBetweenVectors

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the angle between two vectors.

Syntax

```
void avl::AngleBetweenVectors
(
 const avl::Vector2D& inVector1,
 const avl::Vector2D& inVector2,
 atl::Optional<avl::RotationDirection::Type> inRotationDirection,
 atl::Optional<float&> outAbsoluteAngle = atl::NIL,
 atl::Optional<float&> outDirectedAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inVector1	const Vector2D&		Start vector
→	inVector2	const Vector2D&		Target vector
→	inRotationDirection	Optional<RotationDirection::Type>	NIL	Clockwise, counter-clockwise or automatic (by smaller angle)
←	outAbsoluteAngle	Optional<float&>	NIL	Angle value used for measurements <0; 360>
←	outDirectedAngle	Optional<float&>	NIL	Angle value used for clockwise transformations <-360; 360>

Optional Outputs

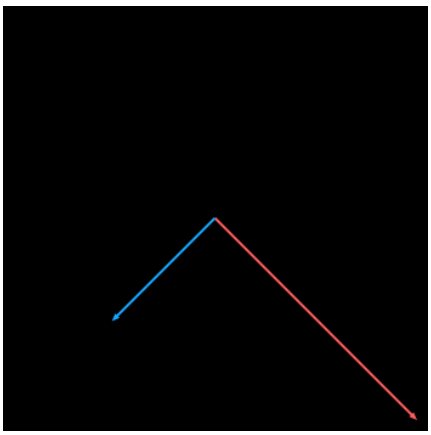
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAbsoluteAngle**, **outDirectedAngle**.

Read more about Optional Outputs.

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when a zero vector is given on input.

Examples



AngleBetweenVectors *performed on two vectors:* ***inVector1*** *DeltaX = 10, DeltaY = 10,* ***inVector2*** *DeltaX = -5, DeltaY = 5,* ***inRotationDirection*** *= CounterClockwise.*
outAbsoluteAngle *returns* ***270****, and* ***outDirectedAngle*** *returns* ***-270****.*

NormalizeAngle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Normalizes an angle to the range <x, x+90) or <x, x+180) or <x, x+360).

Syntax

```
void avl::NormalizeAngle
(
 float inAngle,
 avl::AngleRange::Type inAngleRange,
 float inBaseAngle,
 float& outNormalizedAngle
)
```

Parameters

	Name	Type	Default	Description
→	inAngle	float		
→	inAngleRange	AngleRange::Type	_0_180	Length of the normalization range: 90, 180 or 360
→	inBaseAngle	float	0.0f	The beginning of the normalization range
←	outNormalizedAngle	float&		

33. Geometry 3D Angle Metrics

Table of content:

- AngleBetweenLines3D
- AngleBetweenPlanes
- AngleBetweenSegments3D
- AngleBetweenThreePoints3D
- AngleBetweenVectors3D

AngleBetweenLines3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the smaller and the larger angle between two lines in 3D.

Syntax

```
void avl::AngleBetweenLines3D
(
 const avl::Line3D& inLine1,
 const avl::Line3D& inLine2,
 atl::Optional<float&> outSmallerAngle = atl::NIL,
 atl::Optional<float&> outLargerAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inLine1	const Line3D&		
→	inLine2	const Line3D&		
←	outSmallerAngle	Optional<float&>	NIL	
←	outLargerAngle	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSmallerAngle**, **outLargerAngle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in AngleBetweenLines3D.

AngleBetweenPlanes

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the smaller and the larger angle between two planes in 3D.

Syntax

```
void avl::AngleBetweenPlanes
(
 const avl::Plane3D& inPlane1,
 const avl::Plane3D& inPlane2,
 atl::Optional<float&> outSmallerAngle = atl::NIL,
 atl::Optional<float&> outLargerAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPlane1	const Plane3D&		
→	inPlane2	const Plane3D&		
←	outSmallerAngle	Optional<float&>	NIL	
←	outLargerAngle	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSmallerAngle**, **outLargerAngle**.

Read more about Optional Outputs.

Description

The operation returns the single measure of the angle between two planes in 3D, which is equal to the angle between their normal vectors.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in AngleBetweenPlanes.

AngleBetweenSegments3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the angle between two segments in 3D.

Syntax

```
void avl::AngleBetweenSegments3D
(
 const avl::Segment3D& inSegment1,
 const avl::Segment3D& inSegment2,
 float& outAngle
)
```

Parameters

	Name	Type	Default	Description
→	inSegment1	const Segment3D&		First segment
→	inSegment2	const Segment3D&		Second segment
←	outAngle	float&		Angle value used for measurements <0; 180>

AngleBetweenThreePoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the angle defined by three consecutive points in 3D.

Syntax

```
void avl::AngleBetweenThreePoints3D
(
 const avl::Point3D& inPoint1,
 const avl::Point3D& inPoint2,
 const avl::Point3D& inPoint3,
 float& outAngle
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point3D&		A point on one arm of an angle
→	inPoint2	const Point3D&		The middle point
→	inPoint3	const Point3D&		A point on another arm of the angle
←	outAngle	float&		Angle value used for measurements <0; 180>

AngleBetweenVectors3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the angle between two vectors in 3D.

Syntax

```
void avl::AngleBetweenVectors3D
(
 const avl::Vector3D& inVector1,
 const avl::Vector3D& inVector2,
 float& outAngle
)
```

Parameters

	Name	Type	Default	Description
→	inVector1	const Vector3D&		Start vector
→	inVector2	const Vector3D&		Target vector
←	outAngle	float&		Angle value used for measurements <0; 180>

AnnotateGridPoints

Header: AVL.h
Namespace: avl
Module: Calibration

Select a subset of the given points that forms a grid and assign 2D indices to them.

Applications: Recognition of a custom regular grid for the purpose of camera calibration.

Syntax

```
void avl::AnnotateGridPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<float> inMinDistance,
 atl::Optional<float> inMaxDistance,
 const float inAngleTolerance,
 atl::Array<avl::AnnotatedPoint2D>& outImageGrid,
 atl::Array<avl::Segment2D>& diagValidSubgraph
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Points to calculate a grid
→	inMinDistance	Optional<float>	0.0 – ∞	NIL	Minimum distance between two rows or two columns in pixels
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximum distance between two rows or two columns in pixels
→	inAngleTolerance	const float	0.0 – 90.0	10.0f	Maximum deviation from right angles in the grid
←	outImageGrid	Array<AnnotatedPoint2D>&			Detected grid
🔍	diagValidSubgraph	Array<Segment2D>&			Graph forming a valid grid

AnnotateGridPoints_DeprecatedDeprecated

Header: AVL.h
Namespace: avl
Module: Calibration

Select a subset of the given points that forms a grid and assign world plane coordinates to them.

Applications: Recognition of a custom regular grid, other than the standard chessboard, for the purpose of camera calibration.

Syntax

```
void avl::AnnotateGridPoints_DeprecatedDeprecated
(
 const atl::Array<avl::Point2D>& inPoints,
 const float inScale,
 atl::Optional<float> inMinDistance,
 const float inMaxDistance,

 const atl::Optional<float> inBaseAspectRatio,
 const atl::Optional<float> inBaseShear,
 const atl::Optional<float> inBaseOrientation,
 atl::Array<avl::AnnotatedPoint2D>& outPointGrid,
 atl::Array<avl::Segment2D>& diagValidSubgraph,
 float& diagMaxLength
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inPoints	const Array<Point2D>&			
➡	inMaxAttempts	const Optional<int>	1 – ∞	NIL	Maximum number of attempts at finding the grid
➡	inMaxOutlierCount	const Optional<int>	0 – ∞	NIL	Determines how many outlier points can be present to end the search
➡	inMinLength	const float	0.0 – ∞	0.0f	Minimum length of a grid segment
➡	inMaxLength	const Optional<float>	0.0 – ∞	10.0f	Maximum length of a grid segment, if set to Auto it will be approximated
➡	inMaxLengthRatio	const float	1.0 – 2.0	1.3f	Maximum ratio of two consecutive segments in the grid
➡	inAngleRange	const float	0.0 – 45.0	16.0f	Maximum variation of angles between neighbouring grid segments in degrees
➡	inBaseAspectRatioRange	const float	0.0 – 1.0	0.3f	Maximum variation of the base aspect ratio (ignores if base aspect ratio is not given)
➡	inBaseAspectRatio	const Optional<float>	0.3 – 1.0	1.0f	A reference aspect ratio of the grid
➡	inBaseShear	const Optional<float>	0.0 – 60.0	00.0f	A reference shear angle between grid directions
➡	inBaseOrientation	const Optional<float>	0.0 – 360.0	NIL	A reference orientation of one of the grids directions
⬅	outPointGrid	Array<AnnotatedPoint2D>&			Detected grid
🔍	diagValidSubgraph	Array<Segment2D>&			Graph forming a valid grid
🔍	diagMaxLength	float&			Max length computed by the filter (applicable if inMaxLength is set to Auto)

Description

This filter analyzes a 2D point array and finds a grid within it. The grid can have missing points as well as noise (points that are not vertices of the gird). The filter provides various input that allow the user to specify the shape of the grid that they want to be found.

It is expected that the point array given does not have a lot of missing and/or noise points.

The filter uses a RANSAC based algorithm to find grid within the input array and returns the grid that includes the most points from the input array among all grids that were found. If more than one grid include the maximum number of points, the returned one is the one with the smallest angle deviations.

The algorithm starts by finding a grid base, which consists of three points: one that will be considered as the origin of the grid, one that is one unit away from the origin on the grids X axis and one that is one unit away on the grids Y axis. The constraints for these grid bases can be specified by the user with the use of Base parameters:

- **inBaseAspectRatio** defines the length ratio between the two segments that the grid base consists of (one along the X axis and the other along the Y axis). The ratio is calculated by divining the length of the shorter segment by the length of the longer one. If this parameter is set to Auto, the algorithm will check bases with rations in the range 0.3 – 1.0
- **inBaseAspectRatioRange** defines how much the given base aspect ratio can differ from the calculated one.
- **inBaseShear** defines the shear of the grid in degrees. The calculated shear can differ from the one given in this parameter by **inAngleRange** degrees. If this parameter is not given, bases with shears up to 60 degrees will be considered but grids with shears closer to zero will be preferred.
- **inBaseOrientation** defines the orientation of the grids X axis. If this parameters is not given then the positive X direction of the grid will be defined as the direction that gives the biggest positive change in real X coordinated.

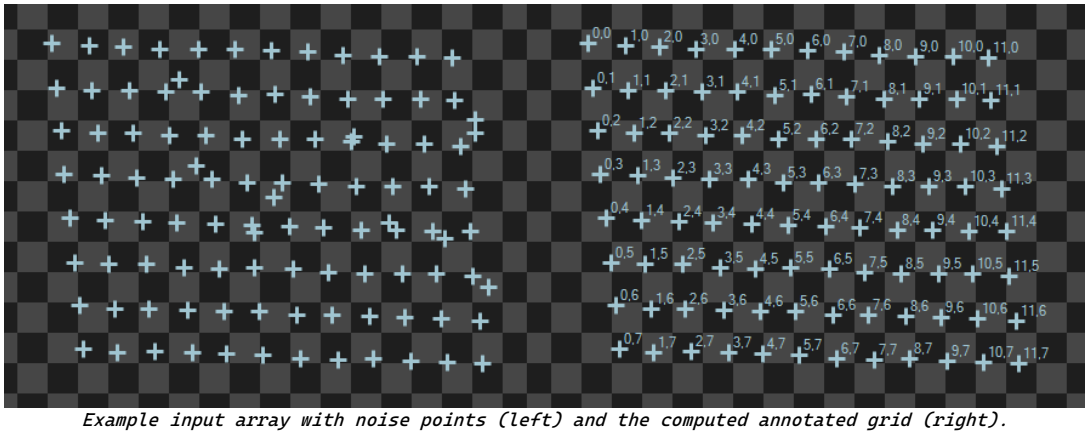
The grid is build from the base with respect to constraint parameters:

- **inMinLength** and **inMaxLength** define the range of possible segment length in the grid (a segment is a single step in either the X or Y direction).
- **inMaxLengthRatio** the maximum length ratio between to neighbouring segments of the grid that are along the same axis (for example: two neighbouring segments along the X axis). The minimum length ratio is calculated as 1 / **inMaxLengthRatio**.
- **inAngleRange** defines how much the angles of neighbouring grid segments can differ.

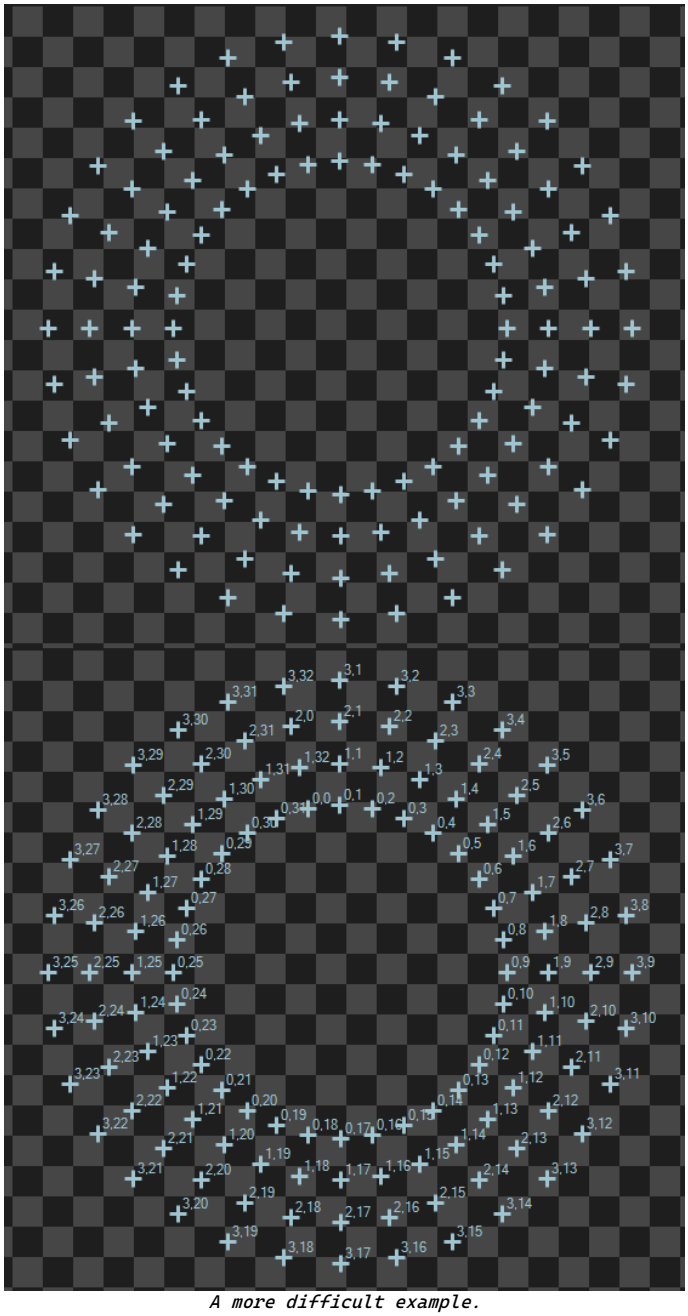
Hints

- The computation time of the filter can be decreased by lowering **inMaxAttempts**.
- The computation time of the filter can be greatly optimized with the **inMinLength** and **inMaxLength** parameters. As they allow the algorithm to filter out a lot of grids early on.
- **inBaseOrientation** can be used to increase the stability of detected grids. This is especially useful for grids the are rotated by 45 degrees, as the X and Y directions of the grid are harder to determine just by looking at positive X changes in the grid.

Examples



Example input array with noise points (left) and the computed annotated grid (right).



A more difficult example.

CalibrateCamera_LineScan

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the line scan camera intrinsic parameters from calibration grid.

Applications: Computes camera parameters which need to be calculated only once for each camera, and are a prerequisite for other calibration filters.

Syntax

```
void avl::CalibrateCamera_LineScan
(
 const atl::Array<avl::AnnotatedPoint2D>& inImageGrid,
 float inGridSpacing,
 int inImageWidth,
 avl::LensDistortionModelType::Type inDistortionType,
 float inImagePointsStandardDeviation,
 atl::Optional<float> inFocalLength,
 avl::LineScanCameraModel& outCameraModel,
 float& outApproxScaleRatio,
 atl::Optional<float&> outRmsError = atl::NIL,
 atl::Optional<float&> outMaxReprojectionError = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outReprojectionErrorSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageGrid	const Array<AnnotatedPoint2D>&			Annotated calibration grid
→	inGridSpacing	float	0.000001 – ∞		Real-world distance between adjacent grid points.
→	inImageWidth	int	1 – ∞		Image width, used for initial estimation of principal point.
→	inDistortionType	LensDistortionModelType::Type		Polynomial	Lens distortion model
→	inImagePointsStandardDeviation	float	0.0 – ∞	0.1f	Assumed uncertainty of inImagePoints. Used for robust optimization.
→	inFocalLength	Optional<float>		NIL	Specify a fixed focal length, in pixels. In order to calculate the inFocalLength from camera parameters one needs to divide the lens focal length [mm] by sensor pitch [mm/pix].
←	outCameraModel	LineScanCameraModel&			
←	outApproxScaleRatio	float&			Approximate scale ratio between Y and X. Useful for camera/encoder trigger rate configuration. When greater than 1, the image is stretched in Y dimension, when less than 1 it is compressed.
←	outRmsError	Optional<float&>		NIL	Final reprojection RMS error, in pixels.
←	outMaxReprojectionError	Optional<float&>		NIL	Maximum reprojection error among all points.
←	outReprojectionErrorSegments	Optional<Array<Segment2D>&>		NIL	Array of segments connecting input image points to grid reprojections.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRmsError**, **outMaxReprojectionError**, **outReprojectionErrorSegments**.

Read more about Optional Outputs.

Description

The filter estimates intrinsic parameters of whole line scan camera system, which consist of a camera and a moving conveyor belt. Such approach, in contrast with area scan camera calibration, is necessary as the moving element of line scan camera system is tightly bound within the image acquisition geometry. This allows for handling distortions caused by:

- intrinsic lens distortions
- image shear caused by deviation from right angle between conveyor belt motion and the camera line
- nonuniform image scaling caused by deviation from ideal encoder trigger period
- 1D perspective effects caused by deviation from right angle between camera optical axis and the imaged plane

Calibration uses a planar calibration grid to perform robust minimization of RMS reprojection error – the square root of averaged squared distances between grid points as observed on the image and their associated grid coordinates projected onto image plane using estimated parameters.

The calibration routine cannot estimate focal length by itself, however it can be set to a fixed value via **inFocalLength**. The **inFocalLength** is measured in pixels, it can be calculated from the sensor and lens parameters:

$$f_{pix} = \frac{f_{lens}}{pp \cdot d}$$

where f_pix – focal length measured in pixels, f_lens – focal length of lens measured in millimeters, pp – sensor pixel pitch measured in millimeters per pixel, d – camera binning or/and image downscaling factor

The **inFocalLength** can also be obtained from angle of view:

$$f_{pix} = \frac{w}{2 \cdot tan(\frac{\alpha}{2})}$$

where f_pix – focal length measured in pixels, w – image width, alpha – angle of view

Only the divisional and polynomial lens distortion models are supported for line scan cameras. The divisional supports most use cases and has predictable behaviour even when calibration data is sparse. Polynomial model may be more accurate but it needs a larger dataset of high quality calibration points across the whole image.

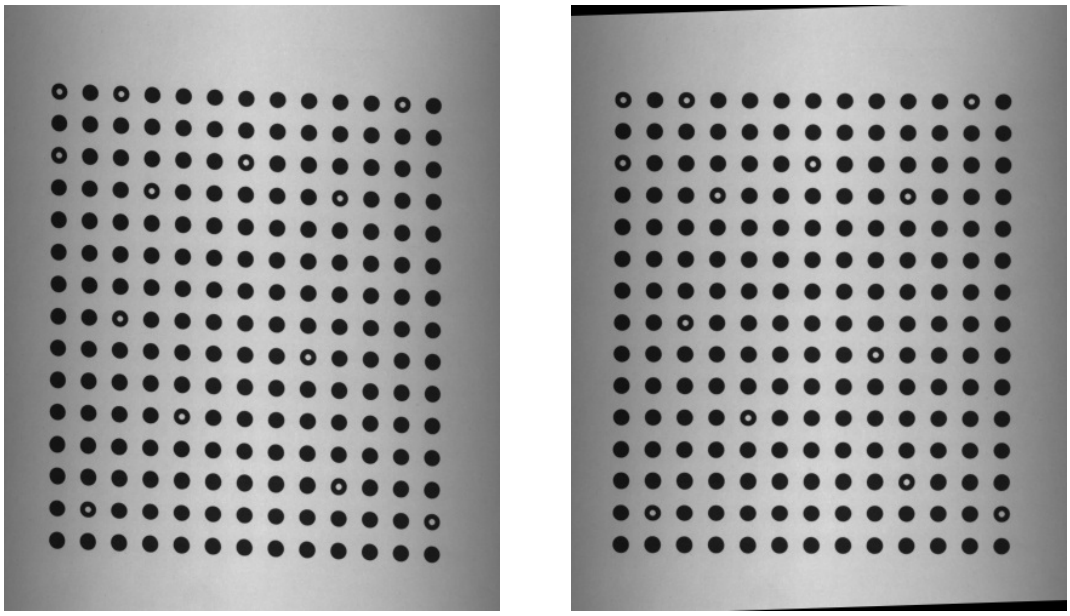
The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsError** is the final RMS reprojection error. The main contributor to that value is the random noise in **inImageGrid** points positions. Model mismatch will also result in increased **outRmsError**.
- The **outMaxReprojectionError** is the maximum reprojection error, can be used to judge if there are outliers in the calibration data.
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of gross errors. The XY scatter plot of residual vectors (obtained by using SegmentVector on the **outReprojectionErrorSegments**) is a good insight into the residuals distribution, which in ideal case should follow a 2D gaussian distribution centered around point (0,0).

Hints

- High accuracy camera calibration needs a considerable amount of high quality calibration points, especially when using more complicated models. Calibration image should contain hundreds of calibration points spanning the area of interest. The calibration grids should be as flat and stiff as possible (cardboard is not a proper backing material, thick glass is perfect). Take care of proper conditions when taking the calibration images: minimize motion blur by proper lighting, prevent reflections from the calibration surface (ideally use diffusion lighting).
- When the focal length of the camera is not provided via **inFocalLength**, the calculated model will lack that value. Despite that, some operations will still work properly, such as distortion removal, or basic image to world plane calibration (CalibrateWorldPlane_* filters).

Examples



Left: calibration grid as captured by the line scan camera. Right: rectified image with shear distortion eliminated.

Remarks

Note, that the calibration routine assumes that the camera line spans the image along its width (i.e. consecutive image rows correspond to consecutive camera acquisitions).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty input grid
DomainError	inGridSpacing needs to be positive
DomainError	Thin prism lens distortion is not supported for line scan cameras.

→	inDistortionType	LensDistortionModelType::Type		Polynomial	Lens distortion model
→	inImagePointsStandardDeviation	float	0.0 – ∞	0.1f	Assumed uncertainty of inImagePoints. Used for robust optimization and outCameraModelStdDev estimation.
→	inFocalLength	Optional<float>		NIL	Specify a fixed focal length (do not estimate), in pixels. In order to calculate the inFocalLength from camera parameters one needs to divide the lens focal length [mm] by sensor pitch [mm/pix].
←	outCameraModel	PinholeCameraModel&			
←	outCameraModelStdDev	Optional<PinholeCameraModel&>		NIL	Standard deviations of all model parameters, assuming that inImagePoints positions have a standard deviation equal to inImagePointsStandardDeviation.
←	outRmsError	Optional<float&>		NIL	Final reprojection RMS error, in pixels.
←	outMaxReprojectionErrors	Optional<Array<float>&>		NIL	For each view: the maximum reprojection error among all points.
←	outReprojectionErrorSegments	Optional<Array<Array<Segment2D>>&>		NIL	For each view: array of segments connecting input image points to grid reprojections.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCameraModelStdDev**, **outRmsError**, **outMaxReprojectionErrors**, **outReprojectionErrorSegments**.

Read more about Optional Outputs.

Description

The filter estimates intrinsic camera parameters - focal length, principal point location and distortion coefficients from a set of planar calibration grids by means of robust minimization of RMS reprojection error - the square root of averaged squared distances between grid points as observed on the image and their associated grid coordinates projected onto image plane using estimated parameters (i.e. grid poses and camera parameters).

The focal length can be calculated by the filter if at least one calibration grid is not perpendicular to the optical axis of the camera. Alternatively, the focal length can be set to a fixed value via **inFocalLength**. The **inFocalLength** is measured in pixels, it can be calculated from the sensor and lens parameters:

$$f_{pix} = \frac{f_{lens}}{pp \cdot d}$$

where f_pix - focal length measured in pixels, f_lens - focal length of lens measured in millimeters, pp - sensor pixel pitch measured in millimeters per pixel, d - camera binning or/and image downscaling factor

The **inFocalLength** can also be obtained from angle of view, for horizontal case following equation applies:

$$f_{pix} = \frac{w}{2 \cdot tan(\frac{\alpha}{2})}$$

where f_pix - focal length measured in pixels, w - image width, alpha - horizontal angle of view

A few distortion model types are supported. The simplest - divisional - supports most use cases and has predictable behaviour even when calibration data is sparse. Higher order models can be more accurate, however they need a much larger dataset of high quality calibration points, and are usually needed for

achieving high levels of positional accuracy across the whole image - order of magnitude below 0.1 pix. Of course this is only a rule of thumb, as each lens is different and there are exceptions.

Distortion model types are compatible with OpenCV, and are expressed with equations using normalized image coordinates:

$$x'' = x' \frac{1}{1 + k_4 \cdot r^2}$$
$$y'' = y' \frac{1}{1 + k_4 \cdot r^2}$$

Divisional distortion model

$$x'' = x'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + 2p_1 x' y' + p_2(r^2 + 2x'^2)$$

$$y'' = y'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + p_1(r^2 + 2y'^2) + 2p_2 x' y'$$

Polynomial distortion model

$$x'' = x'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + 2p_1 x' y' + p_2(r^2 + 2x'^2) + s_1 r^2 + s_2 r^4$$

$$y'' = y'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + p_1(r^2 + 2y'^2) + 2p_2 x' y' + s_3 r^2 + s_4 r^4$$

PolynomialWithThinPrism distortion model

where $r^2 = x'^2 + y'^2$, x' and y' are undistorted, x'' and y'' are distorted normalized image coordinates.

Although every application should be evaluated separately the general guidelines for choosing the right distortion type you will find in table below:

		Required calibration data:		Typical application:	Suggested Lens type:
		Quality:	Quantity:		
Distortion model	Divisional	Average	Average	Robot Guidance	Pinhole
	Polynomial	Very high. Calibration plate should be made of stiff material like metal plate or glass.	Very high evenly distributed across entire ROI. Calculation on areas not covered with calibration plate might be highly inaccurate.	Metrology	Pinhole/Telecentric
	Polynomial with thin prism			Metrology in micrometers	Telecentric

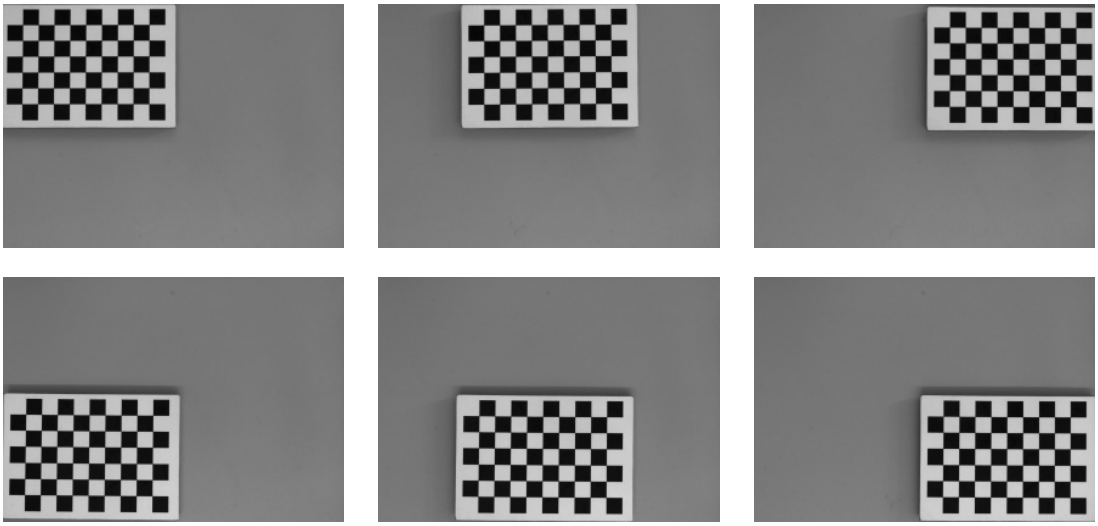
The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsError** is the final RMS reprojection error. The main contributor to that value is the random noise in **inImageGrids** points positions. Model mismatch will also result in increased **outRmsError**.
- The **outMaxReprojectionErrors** is an array of maximum reprojection errors, per view. It can be used to find suspicious calibration grids.
- The **outCameraModelStdDev** contains standard deviations of all parameters of estimated model, assuming that **inImageGrids** points positions have a standard deviation equal to **inImagePointsStandardDeviation**. It can be used to verify the stability of estimated parameters. High values may be a result of data deficiency in a sensitive region (e.g. lack of calibration points at the edges of image when high-order distortion model is used).
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of gross errors. The XY scatter plot of residual vectors (obtained by using SegmentVector on the **outReprojectionErrorSegments**) is a good insight into the residuals distribution, which in ideal case should follow a 2D gaussian distribution centered around point (0,0).

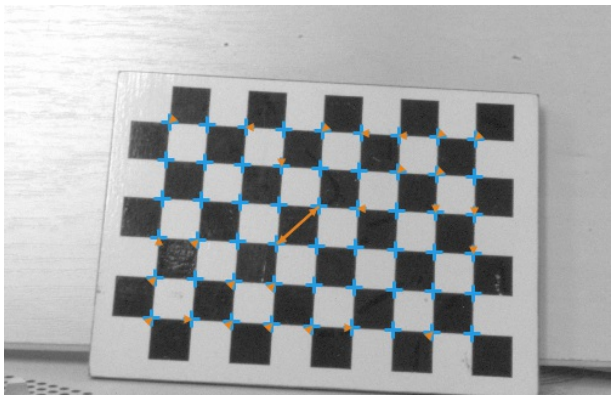
Hints

- High accuracy camera calibration needs a considerable amount of high quality calibration points, especially when using more complicated models. Each calibration image should contain hundreds of calibration points, there should be at least a dozen of calibration images, and all the calibration points should span the area/volume of interest. The calibration grids should be as flat and stiff as possible (cardboard is not a proper backing material, thick glass is perfect). Take care of proper conditions when taking the calibration images: minimize motion blur by proper camera and grid mounts, prevent reflections from the calibration surface (ideally use diffusion lighting).
- There is no need for camera calibration in the production environment, the camera can be calibrated beforehand. As soon as the camera has been assembled with the lens and lens adjustments (zoom/focus/f-stop rings) have been tightly locked, the calibration images can be taken and camera calibration performed. Of course any modifications to the camera-lens setup void the calibration parameters, even apparently minor ones such as removing the lens and putting it back on the camera in seemingly the same position.
- Calibration set containing images of calibration grids that are not perpendicular to the optical axis of the camera allow for automatic focal length estimation. When all calibration grids are perpendicular to the optical axis of the camera and the focal length of the camera is not provided via **inFocalLength**, the calculated model will lack that value. Despite that, some operations will still work properly, such as distortion removal, or basic image to world plane calibration (CalibrateWorldPlane_* filters).
- Note that the pinhole camera calibration doesn't require scale information for its input calibration grids, e.g. when using DetectCalibrationGrid_Chessboard for grid detection, its **inWorldSquareSize** input has no effect on the calibration. Relative scale information between the grid dimensions is still crucial, e.g. when using non-square grid, the aspect ratio of point distances in perpendicular directions must be precisely known.

Examples



A set of grid pictures for basic calibration. Note that high accuracy applications require denser grids and higher amount of pictures.



*Usage of **outReprojectionErrorSegments** for identification of bad association of image points and their grid coordinates in **inImageGrids** - two points are swapped.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty input grid array

Description

The filter estimates intrinsic camera parameters - magnification, principal point location and distortion coefficients from a set of planar calibration grids by means of robust minimization of RMS reprojection error - the square root of averaged squared distances between grid points as observed on the image and their associated grid coordinates projected onto image plane using estimated parameters (i.e. grid poses and camera parameters).

A few distortion model types are supported. The simplest - divisional - supports most use cases and has predictable behaviour even when calibration data is sparse. Higher order models can be more accurate, however they need a much larger dataset of high quality calibration points, and are usually needed for achieving high levels of positional accuracy across the whole image - order of magnitude below 0.1 pix. Of course this is only a rule of thumb, as each lens is different and there are exceptions.

Distortion model types are compatible with OpenCV, and are expressed with equations using normalized image coordinates:

$$x'' = x' \frac{1}{1 + k_4 \cdot r^2}$$
$$y'' = y' \frac{1}{1 + k_4 \cdot r^2}$$

Divisional distortion model

$$x'' = x'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + 2p_1 x' y' + p_2(r^2 + 2x'^2)$$

$$y'' = y'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + p_1(r^2 + 2y'^2) + 2p_2 x' y'$$

Polynomial distortion model

$$x'' = x'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + 2p_1 x' y' + p_2(r^2 + 2x'^2) + s_1 r^2 + s_2 r^4$$

$$y'' = y'(1 + k_1 r^2 + k_2 r^4 + k_3 r^6) + p_1(r^2 + 2y'^2) + 2p_2 x' y' + s_3 r^2 + s_4 r^4$$

PolynomialWithThinPrism distortion model

where $r^2 = x'^2 + y'^2$, x' and y' are undistorted, x'' and y'' are distorted normalized image coordinates.

Although every application should be evaluated separately the general guidelines for choosing the right distortion type you will find in table below:

		Required calibration data:		Typical application:	Suggested Lens type:
		Quality:	Quantity:		
Distortion model	Divisional	Average	Average	Robot Guidance	Pinhole
	Polynomial	Very high. Calibration plate should be made of stiff material like metal plate or glass.	Very high evenly distributed across entire ROI. Calculation on areas not covered with calibration plate might be highly inaccurate.	Metrology	Pinhole/Telecentric
	Polynomial with thin prism			Metrology in micrometers	Telecentric

The filter provides a few methods for judging the feasibility of calculated solution.

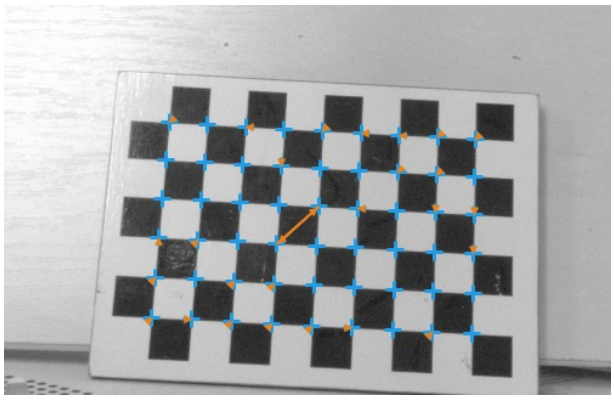
- The **outRmsError** is the final RMS reprojection error. The main contributor to that value is the random noise in **inImageGrids** points positions. Model mismatch will also result in increased **outRmsError**.
- The **outMaxReprojectionErrors** is an array of maximum reprojection errors, per view. It can be used to find suspicious calibration grids.
- The **outCameraModelStdDev** contains standard deviations of all parameters of estimated model, assuming that **inImageGrids** points positions have a standard deviation equal to **inImagePointsStandardDeviation**. It can be used to verify the stability of estimated parameters. High values may be a result of data deficiency in a sensitive region (e.g. lack of calibration points at the edges of image when high-order distortion model is used).
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of gross errors. The XY scatter plot of residual vectors (obtained by using SegmentVector on the **outReprojectionErrorSegments**) is a good insight into the residuals distribution, which in ideal case should follow a 2D gaussian distribution centered around point (0,0).

Hints

High accuracy camera calibration needs a considerable amount of high quality calibration points, especially when using more complicated models. Each calibration image should contain hundreds of calibration points, there should be at least a dozen of calibration images, and all the calibration points should span the area/volume of interest. The calibration grids should be as flat and stiff as possible (cardboard is not a proper backing material, thick glass is perfect). Take care of proper conditions when taking the calibration images: minimize motion blur by proper camera and grid mounts, prevent reflections from the calibration surface (ideally use diffusion lighting).

There is no need for camera calibration in the production environment, the camera can be calibrated beforehand. As soon as the camera has been assembled with the lens and lens adjustments (zoom/focus/f-stop rings) have been tightly locked, the calibration images can be taken and camera calibration performed. Of course any modifications to the camera-lens setup void the calibration parameters, even apparently minor ones such as removing the lens and putting it back on the camera in seemingly the same position.

Examples



*Usage of **outReprojectionErrorSegments** for identification of bad association of image points and their grid coordinates in **inImageGrids** - two points are swapped.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty input array
DomainError	inGridSpacing needs to be positive

See Also

- CalibrateCamera_Pinhole - Finds the camera intrinsic parameters from calibration grids. Uses pinhole camera model (perspective camera).

CalibrateWorldPlane_Default

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image to world plane transformation parameters from world plane calibration grid. World plane origin and axes are unspecified.

Applications: Useful for cases where the position of world plane origin is not important, e.g. distance measurements on a world plane, or image rectification for perspective removal.

Syntax

```
void avl::CalibrateWorldPlane_Default
(
 const atl::Array<avl::AnnotatedPoint2D>& inImageGrid,
 const atl::Optional<const avl::AnyCameraModel&>& inCameraModel,
 float inGridSpacing,
 float inGridThickness,
 avl::RectificationTransform& outTransform,
 atl::Optional<float&> outRmsError = atl::NIL,
 atl::Optional<float&> outMaxReprojectionError = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outReprojectionErrorSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageGrid	const Array<AnnotatedPoint2D>&			Annotated calibration grid
→	inCameraModel	const Optional<const AnyCameraModel&>&		NIL	For undistortion of inImageGrid. If not supplied, the filter will assume that grid came from undistorted image.
→	inGridSpacing	float	0.000001 – ∞	1.0f	Real-world distance between adjacent grid points.
→	inGridThickness	float		0.0f	The world plane will be shifted by given amount in direction perpendicular to the grid to compensate for grid thickness.
←	outTransform	RectificationTransform&			
←	outRmsError	Optional<float&>		NIL	RMS reprojection error, in pixels.
←	outMaxReprojectionError	Optional<float&>		NIL	Maximum reprojection error, in pixels.
←	outReprojectionErrorSegments	Optional<Array<Segment2D>&>		NIL	Array of segments connecting input image points to grid reprojections.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRmsError**, **outMaxReprojectionError**, **outReprojectionErrorSegments**.

Read more about Optional Outputs.

Description

The filter estimates the correspondence between the image plane and a "world plane" – a given planar surface in observed space. The image plane, and thus **inImageGrid** points are assumed to be distorted, and to correct for the distortion the **inCameraModel** (calibration data) needs to be provided. The calculated result – **outTransform** contains all the information for transforming the distorted image plane to the world plane.

The **inCameraModel** is also used to define the type of the planar correspondence. For a standard projective camera (pinhole camera), the planar correspondence is a homography. If the **inCameraModel** is a telecentric camera, the planar correspondence is affine (as there are no perspective parameters in orthographic projection). If no **inCameraModel** is provided, the filter defaults to homography.

The homography requires at least four **inImageGrid** points. The affine relation requires at least three.

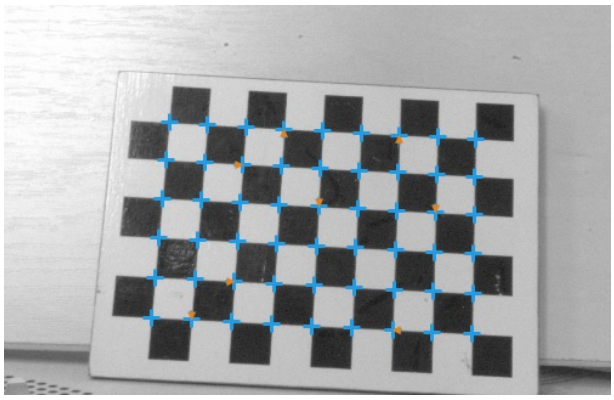
The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsError** and **outMaxReprojectionError**. The main contributor to these values is the random noise in **inImageGrid** points positions. Model mismatch (i.e. trying to calibrate a non-planar object, e.g. wavy surface) will also result in increased reprojection errors. Large difference between **outRmsError** and **outMaxReprojectionError** could be a sign of presence of outliers in input data.
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of per-point reprojection errors.

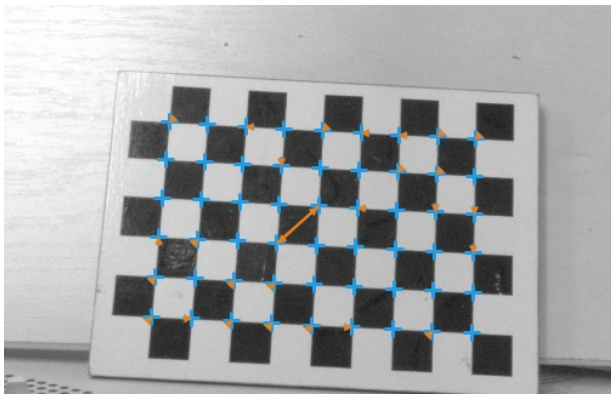
Hints

- Image to world plane coordinate transform can be obtained from as few as 4 point correspondences, however high accuracy calculations need a considerable amount of high quality calibration points. The calibration plane should contain about hundred points, spanning whole area of interest. Take care of proper conditions when taking the calibration images: reduce vibrations that may yield motion blur, prevent reflections from the calibration surface (ideally use diffusion lighting).

Examples



*Good case of image to world plane calibration using high amount of calibration points. Calibration resulted in RMS and maximum reprojection errors less than 1.0, as expected. The **outReprojectionErrorSegments** are not visible at that scale.*



*Example of a gross error. The RMS reprojection error is 17.6, max reprojection error is 91.2, source of these errors is clearly visible thanks to **outReprojectionErrorSegments**: the association of image points and their grid coordinates in **inImageGrid** is wrong.*

Errors

Description

The filter estimates the correspondence between the image plane and a "world plane" - a given planar surface in observed space. It is capable of using a sparse world coordinate information - a calibration grid for which only a few world plane coordinates are known.

The image plane, and thus **inImageGrid** points are assumed to be distorted, and to correct for the distortion the **inCameraModel** (calibration data) needs to be provided. The calculated result - **outTransform** contains all the information for transforming the distorted image plane to the world plane.

The **inCameraModel** is also used to define the type of the planar correspondence. For a standard projective camera (pinhole camera), the planar correspondence is a homography. If the **inCameraModel** is a telecentric camera, the planar correspondence is affine (as there are no perspective parameters in orthographic projection). If no **inCameraModel** is provided, the filter defaults to homography.

To uniquely define the **outTransform**, the algorithm requires at least four **inImageGrid** points (the affine relation requires at least three), and at least two **inLabeledWorldPoints**.

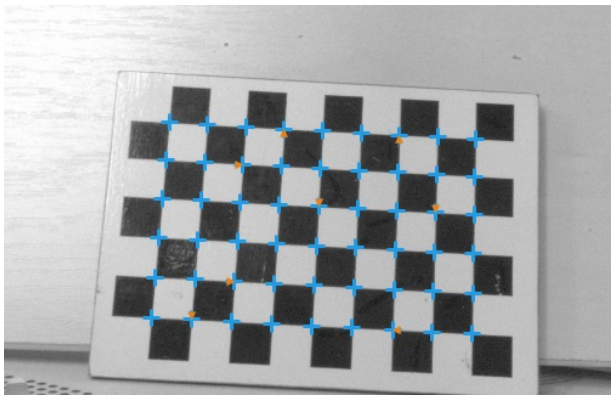
The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsImageError** and **outRmsWorldError** could show if the error is due to the **inImageGrid** or **inLabeledWorldPoints** errors. Model mismatch (i.e. trying to calibrate a non-planar object, e.g. wavy surface) will also result in increased reprojection errors. Large difference between **outRmsImageError** and **outMaxReprojectionError** could be a sign of presence of outliers in **inImageGrid** input data.
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of per-point reprojection errors (excluding the errors due to incorrect world plane labeling).

Hints

- Image to world plane coordinate transform can be obtained from as few as 4 image points (**inImageGrid** points), however high accuracy calculations need a considerable amount of high quality calibration points. The calibration plane should contain about hundred points, spanning whole area of interest. Take care of proper conditions when taking the calibration images: reduce vibrations that may yield motion blur, prevent reflections from the calibration surface (ideally use diffusion lighting).
- It is often assumed that calibration grid is perfect in terms of 2D world coordinates of its points. If such an assumption is made then 2 world coordinates are enough for labeling of grid world point coordinates (**inLabeledWorldPoints**).
- The output reprojection errors are useful tool for assessing the feasibility of computed solution. Note, that the filter outputs two RMS metrics: **outRmsImageError** and **outRmsWorldError**. The **outRmsImageError** characterizes inaccuracies in perspective estimation, it is not influenced by world coordinate labeling. On the other hand, the **outRmsWorldError** characterizes inaccuracies with labeling of grid 2D world coordinate system, excluding perspective estimation. In order for a solution to be feasible, both these errors must be low.

Examples



*Good case of image to world plane calibration using high amount of calibration points. Calibration resulted in RMS and maximum reprojection errors less than 1.0, as expected. The **outReprojectionErrorSegments** are not visible at that scale.*

Read more about Optional Outputs.

Description

The filter estimates the correspondence between the image plane and a "world plane" - a given planar surface in observed space. It is capable of using a multiple grids with sparse world coordinate information - i.e. grids for which only a few world plane coordinates are known.

The image plane, and thus **inImageGrids** points are assumed to be distorted, and to correct for the distortion the **inCameraModel** (calibration data) needs to be provided. The calculated result - **outTransform** contains all the information for transforming the distorted image plane to the world plane.

Currently, only pinhole camera model is supported, so the planar correspondence used is a homography.

For each grid, the algorithm requires at least four **inImageGrids** points. At least two **inLabeledWorldPoints** (in total, among all grids) are required to uniquely determine the **outTransform**.

The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsImageError** and **outRmsWorldError** could show if the error is due to the **inImageGrids** or **inLabeledWorldPoints** errors. Model mismatch (i.e. trying to calibrate a non-planar object, e.g. wavy surface) will also result in increased reprojection errors. Large difference between **outRmsImageError** and **outMaxReprojectionErrors** could be a sign of presence of outliers in **inImageGrids** input data.
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of per-point reprojection errors (excluding the errors due to incorrect world plane labeling).

Hints

- Image to world plane coordinate transform can be obtained from as few as 4 image points (**inImageGrids** points), however high accuracy calculations need a considerable amount of high quality calibration points. The calibration plane should contain about hundred points, spanning whole area of interest. Take care of proper conditions when taking the calibration images: reduce vibrations that may yield motion blur, prevent reflections from the calibration surface (ideally use diffusion lighting).
- The output reprojection errors are useful tool for assessing the feasibility of computed solution. Note, that the filter outputs two RMS metrics: **outRmsImageError** and **outRmsWorldError**. The **outRmsImageError** characterizes inaccuracies in perspective estimation, it is not influenced by world coordinate labeling. On the other hand, the **outRmsWorldError** characterizes inaccuracies with labeling of grid 2D world coordinate system, excluding perspective estimation. In order for a solution to be feasible, both these errors must be low.

Errors

- ImagePointsToWorldPlane - Finds the world coordinates of image Points.
- WorldPlanePointsToImage - Finds the image coordinates of world plane Points.
- CreateRectificationMap_PixelUnits - Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Defines the output geometry in pixels.
- CreateRectificationMap_WorldUnits - Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Defines the output geometry in world units.

CalibrateWorldPlane_OffgridOrigin

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image to world plane transformation matrix, with world origin and axes specified in the image coordinates.

Applications: Rather rarely seen special cases where absolute world plane coordinates cannot be specified in terms of calibration grid, but the location of world plane origin is still required. When in doubt, use the CalibrateWorldPlane_Labeled filter.

Syntax

```
void avl::CalibrateWorldPlane_OffgridOrigin
(
 const atl::Array<avl::AnnotatedPoint2D>& inImageGrid,
 const atl::Optional<const avl::AnyCameraModel&>& inCameraModel,
 float inGridSpacing,
 float inGridThickness,
 const atl::Optional<avl::Point2D>& inWorldPlaneOrigin,
 const atl::Optional<avl::Point2D>& inWorldPlaneXAxis,
 avl::RectificationTransform& outTransform,
 atl::Optional<float&> outRmsError = atl::NIL,
 atl::Optional<float&> outMaxReprojectionError = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outReprojectionErrorSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageGrid	const Array<AnnotatedPoint2D>&			Annotated calibration grid
→	inCameraModel	const Optional<const AnyCameraModel&>&		NIL	For undistortion of inImageGrid. If not supplied, the filter will assume that grid came from undistorted image.
→	inGridSpacing	float	0.000001 – ∞	1.0f	Real-world distance between adjacent grid points.
→	inGridThickness	float		0.0f	The world plane will be shifted by given amount in direction perpendicular to the grid to compensate for grid thickness. Note, that inWorldPlaneOrigin and inWorldPlaneXAxis won't be compensated, so they need to be selected on the target world plane, and not on the grid.
→	inWorldPlaneOrigin	const Optional<Point2D>&		NIL	Sets world plane origin (as the image point). The world plane origin will lie at the specified image point. Note, that this point won't be shifted by inGridThickness parameter.
→	inWorldPlaneXAxis	const Optional<Point2D>&		NIL	Sets world plane x axis direction (as the image point). The world plane x axis will lie at the specified image point. Note, that this point won't be shifted by inGridThickness parameter.
←	outTransform	RectificationTransform&			
←	outRmsError	Optional<float&>		NIL	RMS reprojection error, in pixels.
←	outMaxReprojectionError	Optional<float&>		NIL	Maximum reprojection error, in pixels.
←	outReprojectionErrorSegments	Optional<Array<Segment2D>&>		NIL	Array of segments connecting input image points to grid reprojections.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRmsError**, **outMaxReprojectionError**, **outReprojectionErrorSegments**.

Read more about Optional Outputs.

Description

The filter estimates the correspondence between the image plane and a "world plane" – a given planar surface in observed space. The image plane, and thus **inImageGrid** points are assumed to be distorted, and to correct for the distortion the **inCameraModel** (calibration data) needs to be provided. The calculated result – **outTransform** contains all the information for transforming the distorted image plane to the world plane.

The **inCameraModel** is also used to define the type of the planar correspondence. For a standard projective camera (pinhole camera), the planar correspondence is a homography. If the **inCameraModel** is a telecentric camera, the planar correspondence is affine (as there are no perspective parameters in orthographic projection). If no **inCameraModel** is provided, the filter defaults to homography.

The homography requires at least four **inImageGrid** points. The affine relation requires at least three.

This filter allows for setting the world plane origin and x-axis direction in terms of input image points – see the **inWorldPlaneOrigin** and **inWorldPlaneXAxis**. Note that the origin and the axis direction does not need to lie on a grid point, it can be arbitrarily chosen.

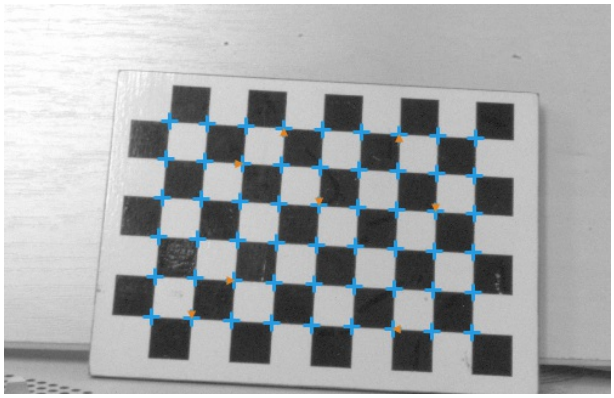
The filter provides a few methods for judging the feasibility of calculated solution.

- The **outRmsError** and **outMaxReprojectionError**. The main contributor to these values is the random noise in **inImageGrid** point positions. Model mismatch (i.e. trying to calibrate a non-planar object, e.g. wavy surface) will also result in increased reprojection errors. Large difference between **outRmsError** and **outMaxReprojectionError** could be a sign of presence of outliers in input data.
- The **outReprojectionErrorSegments** consists of segments connecting input image points to reprojected world points, and thus it can be readily used for visualization of per-point reprojection errors.

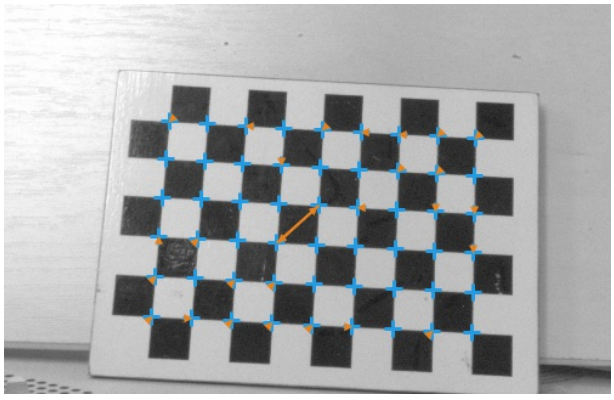
Hints

- Image to world plane coordinate transform can be obtained from as few as 4 point correspondences, however high accuracy calculations need a considerable amount of high quality calibration points. The calibration plane should contain about hundred points, spanning whole area of interest. Take care of proper conditions when taking the calibration images: reduce vibrations that may yield motion blur, prevent reflections from the calibration surface (ideally use diffusion lighting).

Examples



*Good case of image to world plane calibration using high amount of calibration points. Calibration resulted in RMS and maximum reprojection errors less than 1.0, as expected. The **outReprojectionErrorSegments** are not visible at that scale.*



*Example of a gross error. The RMS reprojection error is 17.6, max reprojection error is 91.2, source of these errors is clearly visible thanks to **outReprojectionErrorSegments**: the association of image points and their grid coordinates in **inImageGrid** is wrong.*

Errors

List of possible exceptions:

Error type	Description
DomainError	inGridSpacing needs to be positive

See Also

- CalibrateWorldPlane_Default - Finds the image to world plane transformation parameters from world plane calibration grid. World plane origin and axes are unspecified.
- CalibrateWorldPlane_Labeled - Finds the image to world plane transformation parameters using sparse world coordinate information, i.e. world coordinates are known for only a few points of the grid.
- CalibrateWorldPlane_Multigrid - Finds the image to world plane transformation parameters using multiple grids, using sparse world coordinate information.
- CalibrateWorldPlane_Manual - Finds the image to world plane transformation parameters. Image and their corresponding world points are directly specified (no grid needed).
- CalibrateCamera_Pinhole - Finds the camera intrinsic parameters from calibration grids. Uses pinhole camera model (perspective camera).
- CalibrateCamera_Telecentric - Finds the telecentric camera intrinsic parameters from calibration grids.

- CreateRectificationMap_WorldUnits - Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Defines the output geometry in world units.

ConvertRectificationMap

Header: AVL.h
Namespace: avl
Module: Calibration

Converts a rectification map to a different format.

Syntax

```
void avl::ConvertRectificationMap
(
 const avl::RectificationMap& inRectificationMap,
 atl::Optional<avl::PlainType::Type> inNewPixelType,
 atl::Optional<int> inNewDepth,
 const int inNewPitchAlignment,
 atl::Optional<int> inNewPitch,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRectificationMap	const RectificationMap&			
→	inNewPixelType	Optional<PlainType::Type>		NIL	
→	inNewDepth	Optional<int>	1 - 4	NIL	
→	inNewPitchAlignment	const int	0 - +∞	16	
→	inNewPitch	Optional<int>	1 - +∞	NIL	
←	outRectificationMap	RectificationMap&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect inSpatialMap map in ConvertRectificationMap.

CreateRectificationMap_Advanced

Header: AVL.h
Namespace: avl
Module: Calibration

Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Allows for flexible definition of output geometry.

Applications: Rarely seen special edge cases. Usually it is sufficient to use CreateRectificationMap_PixelUnits or CreateRectificationMap_WorldUnits filters.

Syntax

```
void avl::CreateRectificationMap_Advanced
(
 const avl::ImageFormat& inImageFormat,
 const avl::CreateSpatialMapUnit::Type& inCenterPointType,
 const atl::Optional<avl::Point2D>& inCenterPoint,
 const avl::CreateSpatialMapUnit::Type& inOutputSizeType,
 const atl::Optional<float>& inOutputWidth,
 const atl::Optional<float>& inOutputHeight,
 const atl::Optional<float>& inWorldScale,
 bool inInvertedWorldY,
 avl::InterpolationMethod::Type inInterpolationMethod,
 const avl::RectificationTransform& inTransform,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Input image format.
→	inCenterPointType	const CreateSpatialMapUnit::Type&		Pixels	Specifies units of measurement of inCenterPoint.
→	inCenterPoint	const Optional<Point2D>&		NIL	Specifies a point which will be the center of output image. Depending on inCenterPointType it can be either defined in pixels of input image or in world units. Defaults to the center of input image.
→	inOutputSizeType	const CreateSpatialMapUnit::Type&		Pixels	Specifies units of measurement of inOutputWidth and inOutputHeight.
→	inOutputWidth	const Optional<float>&	0.001 – ∞	NIL	Specifies the size of output image. Depending on inOutputSizeType it can be either defined in pixels or world units. Defaults to the size of input image.
→	inOutputHeight	const Optional<float>&	0.001 – ∞	NIL	Specifies the size of output image. Depending on inOutputSizeType it can be either defined in pixels or world units. Defaults to the size of input image.
→	inWorldScale	const Optional<float>&	0.001 – ∞	NIL	[pix / world unit] Specifies the scale for output image. By default scale is calculated such that there will be no rescaling at the inCenterPoint.
→	inInvertedWorldY	bool		False	Set to true if world coordinate system has right-handed orientation, also known as mathematical or standard. This effectively mirrors the rectified image vertically.
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
→	inTransform	const RectificationTransform&			Transform's camera model is needed for undistortion of image, when not supplied the generated map will assume undistorted image on input. Transform's homography is needed for transforming to given world plane, when not supplied the generated map will only remove distortion of image.
←	outRectificationMap	RectificationMap&			

Description

Creates a RectificationMap, which is used by RectifyImage filter for image *rectification* onto a defined *world plane*. Point locations on rectified images are related to the world plane (defined by **inTransform**) only by translation and scaling.

This filter allows for the most flexible definition of output canvas geometry, however for most cases filters CreateRectificationMap_PixelUnits or CreateRectificationMap_WorldUnits suffice.

The filter may be used to generate a map which only removes a lens distortion in the image – to achieve this behaviour attach a camera model directly to **inTransform** (i.e. do not provide a homography matrix).

The **inTransform** may not contain a camera model – in such case the the generated map will assume undistorted image on input.

The output image dimensions, resolution and cropping are specified by:

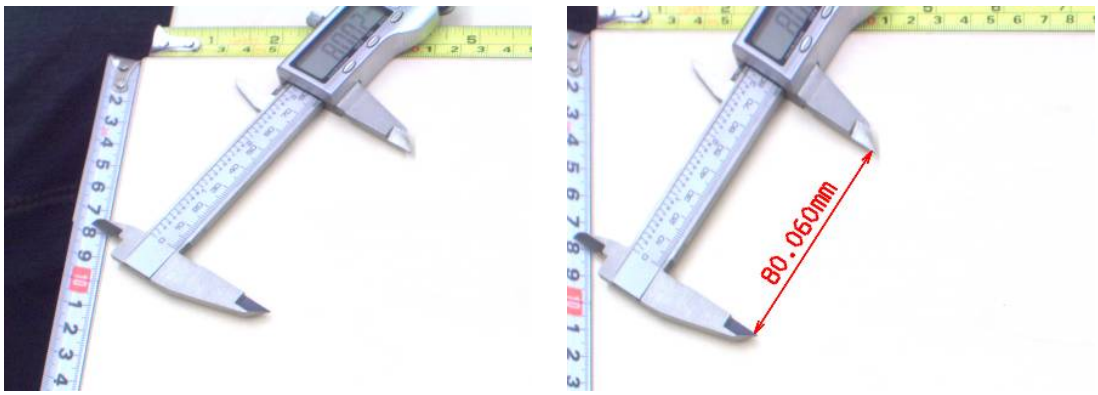
1. **inCenterPoint** – the point which will be the center of output image. Can be selected on the input image or it can be defined in world units – see **inCenterPointType**
2. **inOutputWidth**,**inOutputHeight** – the size of output image, can be defined in output pixels or in world units – see **inOutputSizeType**
3. **inWorldScale** – the scale for output image, defined in pixels per world unit.

For example, if one is interested in area spanning from (0,0) to (10,6) world coordinate, with resolution 100 pixels / world unit, then inputs would be set as follows:

- **inCenterPoint** = (5,3)
- **inCenterPointType** = WorldUnits
- **inOutputWidth** = 10
- **inOutputHeight** = 6
- **inOutputSizeType** = WorldUnits
- **inWorldScale** = 100

Auxiliary data contained inside the RectificationMap describes the relation of rectified image to the world plane.

Examples



Left: original image, as captured by a camera, with mild lens distortion present. Right: rectified image with annotated length measurement.

CreateRectificationMap_Basic

Header: AVL.h
Namespace: avl
Module: Calibration

Computes a spatial map for removing lens and perspective distortion directly from an image containing circles calibration pattern. Internally uses a pinhole camera model with polynomial lens distortion.

Applications: Quick and easy one-step calibration for basic removal of lens and perspective distortions.

Syntax

```
void avl::CreateRectificationMap_Basic
(
 const avl::Image& inImage,
 float inCircleRadius,
 float inCircleDetectionThreshold,
 atl::Array<avl::AnnotatedPoint2D>& outImageGrid,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inCircleRadius	float	1.0 – ∞		Circle radius measured in input image pixels.
→	inCircleDetectionThreshold	float	0.0 – ∞	20.0f	Detection threshold (relative to local image patch).
←	outImageGrid	Array<AnnotatedPoint2D>&			Detected grid, upon which the calibration will be based.
←	outRectificationMap	RectificationMap&			

Errors

List of possible exceptions:

Error type	Description
DomainError	No grid detected in the input image

CreateRectificationMap_PixelUnits

Header: AVL.h
Namespace: avl
Module: Calibration

Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Defines the output geometry in pixels.

Applications: Specification of fixed output geometry allows for constant environment even when recalibration is performed.

Syntax

```
void avl::CreateRectificationMap_PixelUnits
(
 const avl::ImageFormat& inImageFormat,
 const atl::Optional<avl::Point2D>& inCenterPoint,
 const atl::Optional<int>& inOutputWidth,
 const atl::Optional<int>& inOutputHeight,
 const atl::Optional<float>& inWorldScale,
 bool inInvertedWorldY,
 avl::InterpolationMethod::Type inInterpolationMethod,
 const avl::RectificationTransform& inTransform,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Input image format.
→	inCenterPoint	const Optional<Point2D>&		NIL	Specifies a point which will be the center of output image. Defaults to the center of input image.
→	inOutputWidth	const Optional<int>&	1 – ∞	NIL	Specifies the pixel size of output image. Defaults to the size of input image.
→	inOutputHeight	const Optional<int>&	1 – ∞	NIL	Specifies the pixel size of output image. Defaults to the size of input image.
→	inWorldScale	const Optional<float>&	0.001 – ∞	NIL	[pix / world unit] Specifies the scale for output image. By default scale is calculated such that there will be no rescaling at the inCenterPoint.
→	inInvertedWorldY	bool		False	Set to true if world coordinate system has right-handed orientation, also known as mathematical or standard. This effectively mirrors the rectified image vertically.
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
→	inTransform	const RectificationTransform&			Transform's camera model is needed for undistortion of image, when not supplied the generated map will assume undistorted image on input. Transform's homography is needed for transforming to given world plane, when not supplied the generated map will only remove distortion of image.
←	outRectificationMap	RectificationMap&			

Description

Creates a RectificationMap, which is used by RectifyImage filter for image *rectification* onto a defined *world plane*. Point locations on rectified images are related to the world plane (defined by **inTransform**) only by translation and scaling.

The filter may be used to generate a map which only removes a lens distortion in the image – to achieve this behaviour attach a camera model directly to **inTransform** (i.e. do not provide a homography matrix).

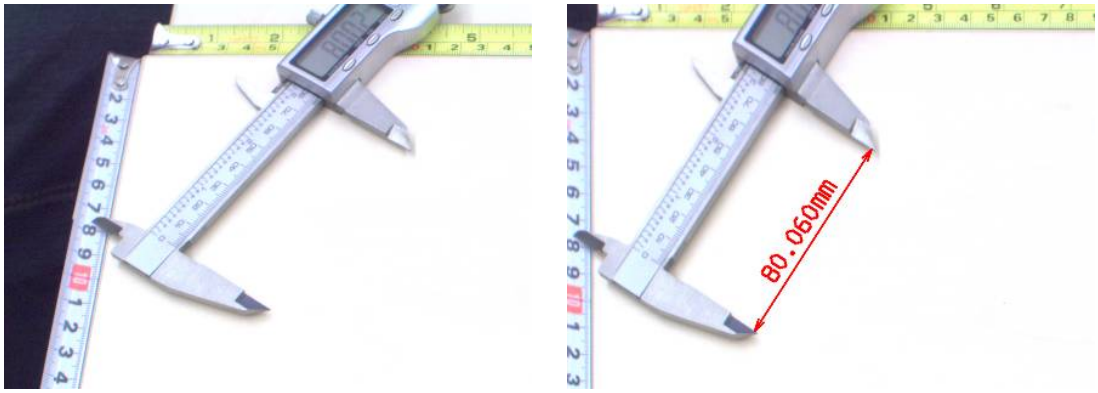
The **inTransform** may not contain a camera model – in such case the the generated map will assume undistorted image on input.

The output image dimensions, resolution and cropping are specified by:

1. **inCenterPoint** – the point on the input image, which will be the center of output image.
2. **inOutputWidth**,**inOutputHeight** – size of output image.
3. **inWorldScale** – the scale for output image, defined in pixels per world unit.

Auxiliary data contained inside the RectificationMap describes the relation of rectified image to the world plane.

Examples



Left: original image, as captured by a camera, with mild lens distortion present. Right: rectified image with annotated length measurement.

CreateRectificationMap_WorldUnits

Header: AVL.h
Namespace: avl
Module: Calibration

Computes a spatial map for transforming distorted images to rectified images defined in world coordinate plane. Defines the output geometry in world units.

Applications: Specification of output geometry in world units is especially useful in image stitching.

Syntax

```
void avl::CreateRectificationMap_WorldUnits
(
 const avl::ImageFormat& inImageFormat,
 float inLeftBound,
 float inRightBound,
 float inTopBound,
 float inBottomBound,
 const atl::Optional<float>& inWorldScale,
 bool inInvertedWorldY,
 avl::InterpolationMethod::Type inInterpolationMethod,
 const avl::RectificationTransform& inTransform,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Input image format.
→	inLeftBound	float			World X coordinate of left side of generated output image.
→	inRightBound	float			World X coordinate of right side of generated output image.
→	inTopBound	float			World Y coordinate of top side of generated output image.
→	inBottomBound	float			World Y coordinate of bottom side of generated output image.
→	inWorldScale	const Optional<float>&	0.001 – ∞	NIL	[pix / world unit] Specifies the scale for output image. By default scale is calculated such that there will be no rescaling at the center of output image.
→	inInvertedWorldY	bool		False	Set to true if world coordinate system has right-handed orientation, also known as mathematical or standard. This effectively mirrors the rectified image vertically.
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
→	inTransform	const RectificationTransform&			Transform's camera model is needed for undistortion of image, when not supplied the generated map will assume undistorted image on input. Transform's homography is needed for transforming to given world plane, when not supplied the generated map will only remove distortion of image.
←	outRectificationMap	RectificationMap&			

Description

Creates a RectificationMap, which is used by RectifyImage filter for image *rectification* onto a defined *world plane*. Point locations on rectified images are related to the world plane (defined by **inTransform**) only by translation and scaling.

The **inTransform** may not contain a camera model – in such case the the generated map will assume undistorted image on input.

The output image dimensions, resolution and cropping are specified by:

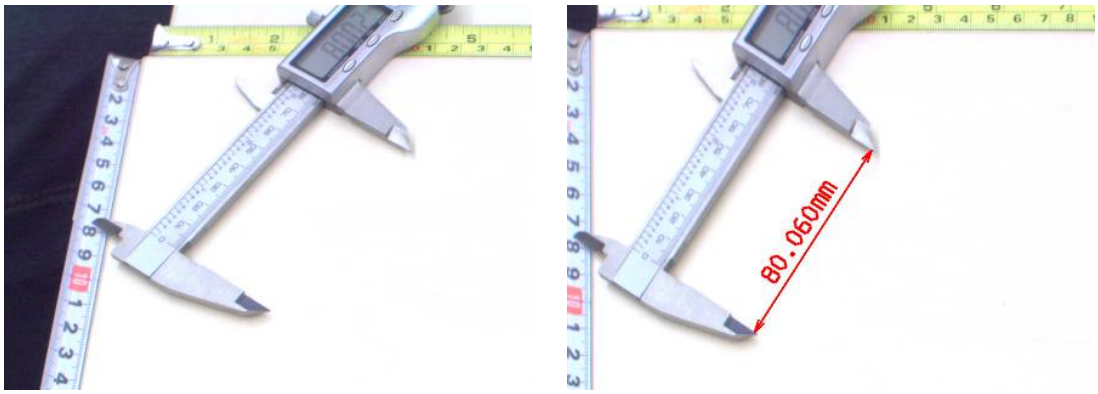
1. **inLeftBound**,**inRightBound**,**inTopBound**,**inBottomBound** – real world coordinate boundaries of the area which output image will cover.
2. **inWorldScale** – the scale for output image, defined in pixels per world unit.

For example, if one is interested in area spanning from (0,0) to (10,6) world coordinate, with resolution 100 pixels / world unit, then inputs would be set as follows:

- **inLeftBound** = 0
- **inRightBound** = 10
- **inTopBound** = 0
- **inBottomBound** = 6
- **inWorldScale** = 100

Auxiliary data contained inside the RectificationMap describes the relation of rectified image to the world plane.

Examples



Left: original image, as captured by a camera, with mild lens distortion present. Right: rectified image with annotated length measurement.

Errors

List of possible exceptions:

Error type	Description
DomainError	inLeftBound should be less than inRightBound
DomainError	inTopBound should be less than inBottomBound

DetectCalibrationGrid_Chessboard

Header: AVL.h
Namespace: avl
Module: Calibration

Detects a chessboard calibration grid on the image, and returns calibration points where 4 chessboard squares meet.

Syntax

```
void avl::DetectCalibrationGrid_Chessboard
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Size& inBoardSize,
 bool inFastApproximate,
 atl::Array<avl::AnnotatedPoint2D>& outImageGrid
)
```

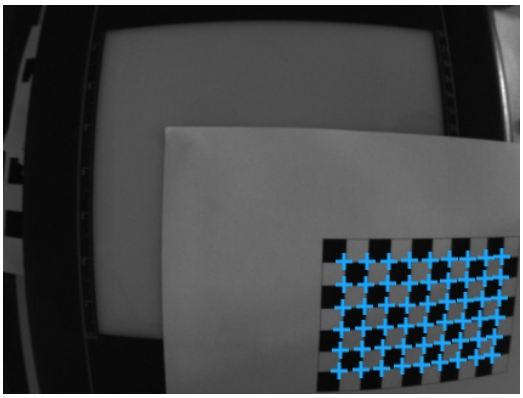
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inBoardSize	const Size&	(Width: 0, Height: 0)	Number of checkerboard squares in X and Y dimensions.
→	inFastApproximate	bool	False	Fast filter execution, but result is approximate.
←	outImageGrid	Array<AnnotatedPoint2D>&		Detected grid

Hints

Make sure that the whole calibration grid is visible in the image. Otherwise, it will not be detected because the detection algorithm requires a few pixels wide quiet zone around the chessboard. Pay attention to the number of columns and rows, as providing misleading data may make the algorithm work incorrectly or not work at all.

Examples



*DetectCalibrationGrid_Chessboard executed with **inBoardSize** = {10,7}*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input image is too small
DomainError	Input image must have pixels of UInt8 type
DomainError	Region of interest exceeds an input image.
DomainError	Specified board is too small, minimum size is 4x4

See Also

- DetectCalibrationGrid_Circles – Detects an arbitrary size symmetric circle pattern on the image.

DetectCalibrationGrid_Circles

Header: AVL.h
Namespace: avl
Module: Calibration

Detects an arbitrary size symmetric circle pattern on the image.

Syntax

```
void avl::DetectCalibrationGrid_Circles
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inCircleRadius,
 float inCircleDetectionThreshold,
 avl::Polarity::Type inCirclePolarity,
 atl::Array<avl::AnnotatedPoint2D>& outImageGrid,
 avl::Region& diagCirclesRegion,
 atl::Array<avl::Point2D>& diagCircleCandidates
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inCircleRadius	float	1.0 – ∞		Circle radius measured in input image pixels.
→	inCircleDetectionThreshold	float	0.0 – ∞	20.0f	Detection threshold (relative to local image patch).
→	inCirclePolarity	Polarity::Type		Any	Circle intensity with respect to background.
←	outImageGrid	Array<AnnotatedPoint2D>&			Detected grid
🔍	diagCirclesRegion	Region&			Image after thresholding, this is the circle detector input.
🔍	diagCircleCandidates	Array<Point2D>&			Detected circle centers, before the grid construction step.

Requirements

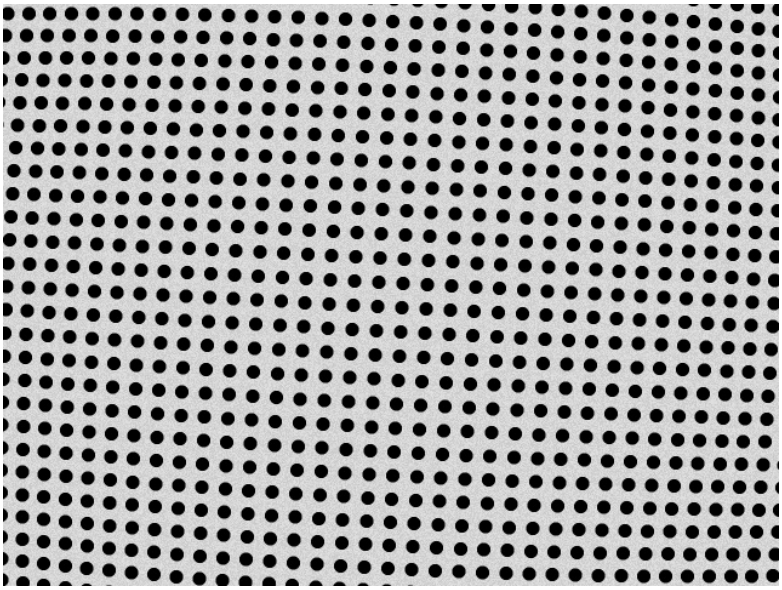
For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

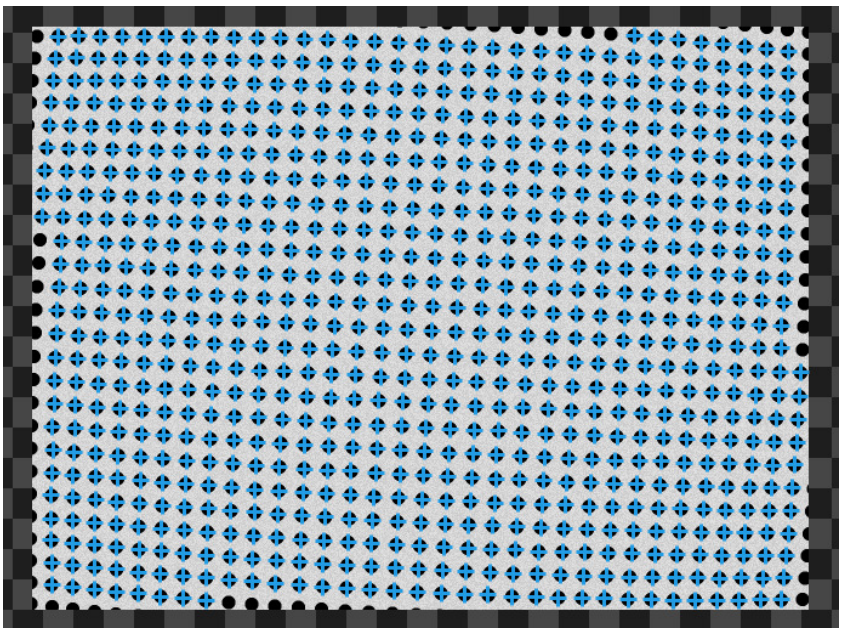
Hints

Circles may have holes. This can utilized, for example, for designating some specific coordinates on the calibration board. Note that the hole diameter must be less than a half of the circle diameter.

Examples



*Input image for DetectCalibrationGrid_Circles executed with **inCircleRadius** = 5*



Detected calibration points

Remarks

The circle pattern must be a rectangular grid, with equal spacing in both dimensions.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format.
DomainError	Region of interest exceeds an input image.
DomainError	Not supported inImage pixel format in DetectCalibrationGrid_Circles. Supported formats: UInt8.

- DetectCalibrationGrid_Chessboard – Detects a chessboard calibration grid on the image, and returns calibration points where 4 chessboard squares meet.

DetectCalibrationGrid_Circles_DeprecatedDeprecated

Header: AVL.h
Namespace: avl
Module: Calibration

Detects an arbitrary size symmetric circle pattern on the image.

Applications: Camera calibration, image to world coordinates transformations.

Syntax

```
void avl::DetectCalibrationGrid_Circles_DeprecatedDeprecated
(
 const avl::Image& inImage,
 float inCircleRadius,
 float inWorldCircleSpacing,
 float inCircleDetectionMinScore,
 atl::Array<avl::Point2D>& outImagePoints,
 atl::Array<avl::Point2D>& outWorldPlanePoints,
 atl::Array<avl::Circle2D>& diagCircleCandidates
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inCircleRadius	float	1.0 – ∞		Circle radius measured in input image pixels.
→	inWorldCircleSpacing	float	0.0 – ∞	1.0f	Real-world distance between adjacent circles centers.
→	inCircleDetectionMinScore	float	0.0 – ∞	20.0f	Minimum matching score for circle detector.
←	outImagePoints	Array<Point2D>&			Image coordinates of detected calibration points.
←	outWorldPlanePoints	Array<Point2D>&			World plane coordinates of detected calibration points.
🔍	diagCircleCandidates	Array<Circle2D>&			Detected circles, before the grid construction step

FilterGridPoints

Header: AVL.h
Namespace: avl
Module: Calibration

Select a subset of the given points that forms a grid.

Syntax

```
void avl::FilterGridPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 const atl::Optional<int> inMaxAttempts,
 const atl::Optional<int> inMaxOutlierCount,
 const float inMinLength,
 const atl::Optional<float> inMaxLength,
 const float inMaxLengthRatio,
 const float inAngleRange,
 const float inBaseAspectRatioRange,
 const atl::Optional<float> inBaseAspectRatio,
 const atl::Optional<float> inBaseShear,
 const atl::Optional<float> inBaseOrientation,
 atl::Array<avl::Point2D>& outPointGrid,
 atl::Array<avl::Segment2D>& diagValidSubgraph,
 float& diagMaxLength
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			
→	inMaxAttempts	const Optional<int>	1 – ∞	NIL	Maximum number of attempts at finding the grid
→	inMaxOutlierCount	const Optional<int>	0 – ∞	NIL	Determines how many outlier points can be present to end the search
→	inMinLength	const float	0.0 – ∞	0.0f	Minimum length of a grid segment
→	inMaxLength	const Optional<float>	0.0 – ∞	10.0f	Maximum length of a grid segment, if set to Auto it will be approximated
→	inMaxLengthRatio	const float	1.0 – 2.0	1.3f	Maximum ratio of two consecutive segments in the grid
→	inAngleRange	const float	0.0 – 45.0	16.0f	Maximum variation of angles between neighbouring grid segments in degrees
→	inBaseAspectRatioRange	const float	0.0 – 1.0	0.3f	Maximum variation of the base aspect ratio (ignores if base aspect ratio is not given)
→	inBaseAspectRatio	const Optional<float>	0.3 – 1.0	1.0f	A reference aspect ratio of the grid
→	inBaseShear	const Optional<float>	0.0 – 60.0	0.0f	A reference shear angle between grid directions that uses inMaxAngleRange as the maximum error range
→	inBaseOrientation	const Optional<float>	0.0 – 360.0	NIL	A reference orientation of one of the grids directions
←	outPointGrid	Array<Point2D>&			Detected grid
🔍	diagValidSubgraph	Array<Segment2D>&			Graph forming a valid grid
🔍	diagMaxLength	float&			Max length computed by the filter (applicable if inMaxLength is set to Auto)

Description

This is a simplified version of AnnotateGridPoints_Ransac. See the documentation of that filter for more detail.

- AnnotateGridPoints_Ransac – Select a subset of the given points that forms a grid and assign 2D indices to them.

GenerateCalibrationPoints

Header: AVL.h
Namespace: avl
Module: Calibration

Generates artificial points for camera calibration. Doesn't support distortion.

Applications: Calibration testing.

Syntax

```
void avl::GenerateCalibrationPoints
(
 int inPointsX,
 int inPointsY,
 float inWorldPointSpacing,
 const avl::Vector3D& inPlaneRotationAxis,
 float inPlaneRotationAngle,
 const avl::Vector3D& inPlaneTranslation,
 avl::CameraModelType::Type inCameraType,
 float inFocalLengthOrMagnificationX,
 atl::Optional<float> inFocalLengthOrMagnificationY,
 atl::Optional<avl::Point2D> inPrincipalPoint,
 const avl::Size& inImageSize,
 atl::Array<avl::AnnotatedPoint2D>& outImageGrid,
 atl::Array<avl::Point2D>& outWorldPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPointsX	int	10	Number of points in X direction on the calibration plane.
→	inPointsY	int	10	Number of points in Y direction on the calibration plane.
→	inWorldPointSpacing	float	1.0f	Distances between consecutive points on the calibration plane.
→	inPlaneRotationAxis	const Vector3D&	(DeltaX: 0.0, DeltaY: 0.0, DeltaZ: 1.0)	Calibration plane rotation axis.
→	inPlaneRotationAngle	float	0.0f	Calibration plane rotation angle.
→	inPlaneTranslation	const Vector3D&	(DeltaX: 0.0, DeltaY: 0.0, DeltaZ: 10.0)	Calibration plane translation (applied after rotation).
→	inCameraType	CameraModelType::Type	PinholeCameraModel	Calibration camera model (pinhole, telecentric or line scan)
→	inFocalLengthOrMagnificationX	float	100.0f	
→	inFocalLengthOrMagnificationY	Optional<float>	NIL	
→	inPrincipalPoint	Optional<Point2D>	NIL	By default is on the center of output image
→	inImageSize	const Size&	(Width: 640, Height: 480)	The size of image that artificial camera captures
←	outImageGrid	Array<AnnotatedPoint2D>&		
←	outWorldPoints	Array<Point2D>&		

ImageEdgesToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Edges.

Syntax

```
void avl::ImageEdgesToWorldPlane
(
 const atl::Array<avl::Edge1D>& inImageEdges,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Edge1D>& outWorldEdges
)
```

Parameters

	Name	Type	Default	Description
→	inImageEdges	const Array<Edge1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldEdges	Array<Edge1D>&		

ImageEdgeToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Edge.

Syntax

```
void avl::ImageEdgeToWorldPlane
(
 const avl::Edge1D& inImageEdge,
 const avl::RectificationTransform& inTransform,
 avl::Edge1D& outWorldEdge
)
```

Parameters

	Name	Type	Default	Description
→	inImageEdge	const Edge1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldEdge	Edge1D&		

ImageGapsToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Gaps.

Syntax

```
void avl::ImageGapsToWorldPlane
(
 const atl::Array<avl::Gap1D>& inImageGaps,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Gap1D>& outWorldGaps
)
```

Parameters

	Name	Type	Default	Description
→	inImageGaps	const Array<Gap1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldGaps	Array<Gap1D>&		

ImageGapToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Gap.

Syntax

```
void avl::ImageGapToWorldPlane
(
 const avl::Gap1D& inImageGap,
 const avl::RectificationTransform& inTransform,
 avl::Gap1D& outWorldGap
)
```

Parameters

	Name	Type	Default	Description
→	inImageGap	const Gap1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldGap	Gap1D&		

ImagePathsToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Paths.

Syntax

```
void avl::ImagePathsToWorldPlane
(
 const atl::Array<avl::Path>& inImagePaths,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Path>& outWorldPaths
)
```

Parameters

	Name	Type	Default	Description
→	inImagePaths	const Array<Path>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldPaths	Array<Path>&		

ImagePathToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Path.

Syntax

```
void avl::ImagePathToWorldPlane
(
 const avl::Path& inImagePath,
 const avl::RectificationTransform& inTransform,
 avl::Path& outWorldPath
)
```

Parameters

	Name	Type	Default	Description
→	inImagePath	const Path&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldPath	Path&		

ImagePointsToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Points.

Syntax

```
void avl::ImagePointsToWorldPlane
(
 const atl::Array<avl::Point2D>& inImagePoints,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Point2D>& outWorldPoints
)
```

Parameters

	Name	Type	Default	Description
→	inImagePoints	const Array<Point2D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldPoints	Array<Point2D>&		

ImagePointToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Point.

Syntax

```
void avl::ImagePointToWorldPlane
(
 const avl::Point2D& inImagePoint,
 const avl::RectificationTransform& inTransform,
 avl::Point2D& outWorldPoint
)
```

Parameters

	Name	Type	Default	Description
→	inImagePoint	const Point2D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldPoint	Point2D&		

ImageRidgesToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Ridges.

Syntax

```
void avl::ImageRidgesToWorldPlane
(
 const atl::Array<avl::Ridge1D>& inImageRidges,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Ridge1D>& outWorldRidges
)
```

Parameters

	Name	Type	Default	Description
→	inImageRidges	const Array<Ridge1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldRidges	Array<Ridge1D>&		

ImageRidgeToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Ridge.

Syntax

```
void avl::ImageRidgeToWorldPlane
(
 const avl::Ridge1D& inImageRidge,
 const avl::RectificationTransform& inTransform,
 avl::Ridge1D& outWorldRidge
)
```

Parameters

	Name	Type	Default	Description
→	inImageRidge	const Ridge1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldRidge	Ridge1D&		

ImageSegmentsToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Segments.

Syntax

```
void avl::ImageSegmentsToWorldPlane
(
 const atl::Array<avl::Segment2D>& inImageSegments,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Segment2D>& outWorldSegments
)
```

Parameters

	Name	Type	Default	Description
→	inImageSegments	const Array<Segment2D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldSegments	Array<Segment2D>&		

ImageSegmentToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Segment.

Syntax

```
void avl::ImageSegmentToWorldPlane
(
 const avl::Segment2D& inImageSegment,
 const avl::RectificationTransform& inTransform,
 avl::Segment2D& outWorldSegment
)
```

Parameters

	Name	Type	Default	Description
→	inImageSegment	const Segment2D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldSegment	Segment2D&		

ImageStripesToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Stripes.

Syntax

```
void avl::ImageStripesToWorldPlane
(
 const atl::Array<avl::Stripe1D>& inImageStripes,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Stripe1D>& outWorldStripes
)
```

Parameters

	Name	Type	Default	Description
→	inImageStripes	const Array<Stripe1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldStripes	Array<Stripe1D>&		

ImageStripeToWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the world coordinates of image Stripe.

Syntax

```
void avl::ImageStripeToWorldPlane
(
 const avl::Stripe1D& inImageStripe,
 const avl::RectificationTransform& inTransform,
 avl::Stripe1D& outWorldStripe
)
```

Parameters

	Name	Type	Default	Description
→	inImageStripe	const Stripe1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for undistortion, when not supplied the filter assumes undistorted input. Transform's homography is needed for transforming coordinates to given world plane, when not supplied the filter only removes distortion of input.
←	outWorldStripe	Stripe1D&		

RectifyImage

Header: AVL.h
Namespace: avl
Module: Calibration

Applies a spatial map to distorted image transforming it to rectified image defined in world coordinates.

Syntax

```
void avl::RectifyImage
(
 const avl::Image& inImage,
 const avl::RectificationMap& inRectificationMap,
 avl::Image& outImage,
 atl::Optional< avl::Matrix& > outRectifiedTransform = atl::NIL,
 atl::Optional< avl::Point2D& > outWorldOrigin = atl::NIL,
 atl::Optional< float& > outWorldScale = atl::NIL,
 atl::Optional< float& > outWorldScaleInv = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRectificationMap	const RectificationMap&		The spatial map with associated data for world coordinates calculation on rectified image. Designed to be set with calibration GUI.
←	outImage	Image&		Remapped image.
←	outRectifiedTransform	Optional< Matrix& >	NIL	For convenient calculation of world coordinates on rectified image. Connects directly to Image...ToWorldPlane and WorldPlane...ToImage filters. The transformation is only translation + scaling.
←	outWorldOrigin	Optional< Point2D& >	NIL	Position of world origin on the rectified image.
←	outWorldScale	Optional< float& >	NIL	[pix / world unit] World scale of the rectified image.
←	outWorldScaleInv	Optional< float& >	NIL	[world unit / pix] Inverse of outWorldScale. Connects directly to inResolution input of filters such as PointToPointDistance.

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRectifiedTransform**, **outWorldOrigin**, **outWorldScale**, **outWorldScaleInv**.

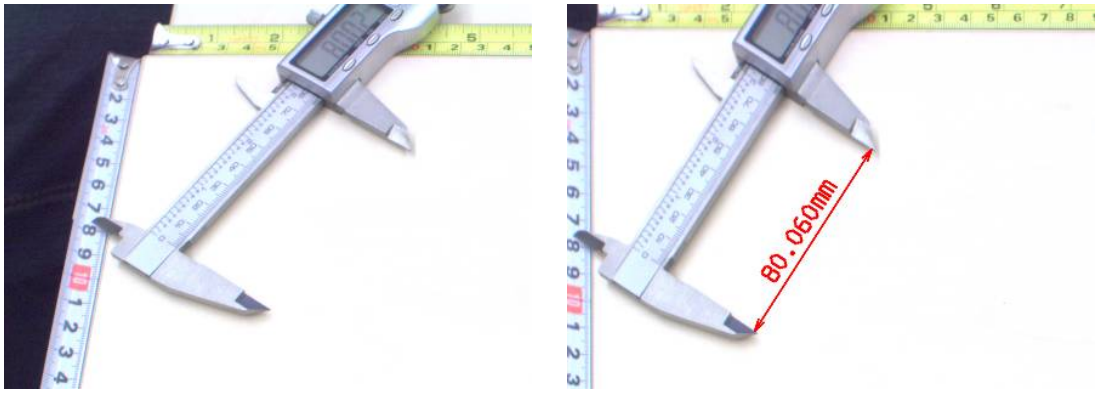
Read more about Optional Outputs.

Description

Uses a RectificationMap computed by CreateRectificationMap* filters (such as CreateRectificationMap_PixelUnits or CreateRectificationMap_WorldUnits) for image *rectification* onto a defined *world plane*. Point locations on rectified images are related to the world plane only by translation and scaling.

Auxiliary outputs **outWorldOrigin** and **outWorldScale** fully describe the relation of rectified image to world plane. For convenience the **outRectifiedTransform** output is provided, which describes the same relation, however it can be directly connected to the ImagePointsToWorldPlane filter family to obtain world coordinates of points detected on the remapped (rectified) image.

Examples



Left: original image, as captured by a camera, with mild lens distortion present. Right: rectified image with annotated length measurement.

See Also

- RemapImage – Applies a precomputed image transform, defined by a spatial map object.

ShiftWorldPlane

Header: AVL.h
Namespace: avl
Module: Calibration

Shifts world plane along its normal vector.

Applications: Correction of already calibrated world plane. Useful for avoiding recalibration when, for example, the product thickness on a conveyor belt changes by a known amount.

Syntax

```
void avl::ShiftWorldPlane
(
 const avl::RectificationTransform& inTransform,
 double inDeltaZ,
 avl::RectificationTransform& outTransform
)
```

Parameters

	Name	Type	Default	Description
→	inTransform	const RectificationTransform&		
→	inDeltaZ	double	0.0D	The world plane will be shifted by given amount in direction perpendicular to the grid. Positive translations move plane away from camera.
←	outTransform	RectificationTransform&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Camera model in inTransform is not defined.
DomainError	Homography matrix in inTransform is not defined.
DomainError	Shifting world plane with non pinhole camera models (e.g. telecentric) is not supported yet.

WorldPlaneEdgesToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Edges.

Syntax

```
void avl::WorldPlaneEdgesToImage
(
 const atl::Array<avl::Edge1D>& inWorldEdges,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Edge1D>& outImageEdges
)
```

Parameters

	Name	Type	Default	Description
→	inWorldEdges	const Array<Edge1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageEdges	Array<Edge1D>&		

WorldPlaneEdgeToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Edge.

Syntax

```
void avl::WorldPlaneEdgeToImage
(
 const avl::Edge1D& inWorldEdge,
 const avl::RectificationTransform& inTransform,
 avl::Edge1D& outImageEdge
)
```

Parameters

	Name	Type	Default	Description
→	inWorldEdge	const Edge1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageEdge	Edge1D&		

WorldPlaneGapsToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Gaps.

Syntax

```
void avl::WorldPlaneGapsToImage
(
 const atl::Array<avl::Gap1D>& inWorldGaps,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Gap1D>& outImageGaps
)
```

Parameters

	Name	Type	Default	Description
→	inWorldGaps	const Array<Gap1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageGaps	Array<Gap1D>&		

WorldPlaneGapToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Gap.

Syntax

```
void avl::WorldPlaneGapToImage
(
 const avl::Gap1D& inWorldGap,
 const avl::RectificationTransform& inTransform,
 avl::Gap1D& outImageGap
)
```

Parameters

	Name	Type	Default	Description
→	inWorldGap	const Gap1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageGap	Gap1D&		

WorldPlanePathsToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Paths.

Syntax

```
void avl::WorldPlanePathsToImage
(
 const atl::Array<avl::Path>& inWorldPaths,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Path>& outImagePaths
)
```

Parameters

	Name	Type	Default	Description
→	inWorldPaths	const Array<Path>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImagePaths	Array<Path>&		

WorldPlanePathToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Path.

Syntax

```
void avl::WorldPlanePathToImage
(
 const avl::Path& inWorldPath,
 const avl::RectificationTransform& inTransform,
 avl::Path& outImagePath
)
```

Parameters

	Name	Type	Default	Description
→	inWorldPath	const Path&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImagePath	Path&		

WorldPlanePointsToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Points.

Syntax

```
void avl::WorldPlanePointsToImage
(
 const atl::Array<avl::Point2D>& inWorldPoints,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Point2D>& outImagePoints
)
```

Parameters

	Name	Type	Default	Description
→	inWorldPoints	const Array<Point2D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImagePoints	Array<Point2D>&		

WorldPlanePointToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Point.

Syntax

```
void avl::WorldPlanePointToImage
(
 const avl::Point2D& inWorldPoint,
 const avl::RectificationTransform& inTransform,
 avl::Point2D& outImagePoint
)
```

Parameters

	Name	Type	Default	Description
→	inWorldPoint	const Point2D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImagePoint	Point2D&		

WorldPlaneRidgesToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Ridges.

Syntax

```
void avl::WorldPlaneRidgesToImage
(
 const atl::Array<avl::Ridge1D>& inWorldRidges,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Ridge1D>& outImageRidges
)
```

Parameters

	Name	Type	Default	Description
→	inWorldRidges	const Array<Ridge1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageRidges	Array<Ridge1D>&		

WorldPlaneRidgeToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Ridge.

Syntax

```
void avl::WorldPlaneRidgeToImage
(
 const avl::Ridge1D& inWorldRidge,
 const avl::RectificationTransform& inTransform,
 avl::Ridge1D& outImageRidge
)
```

Parameters

	Name	Type	Default	Description
➡	inWorldRidge	const Ridge1D&		
➡	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
⬅	outImageRidge	Ridge1D&		

WorldPlaneSegmentsToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Segments.

Syntax

```
void avl::WorldPlaneSegmentsToImage
(
 const atl::Array<avl::Segment2D>& inWorldSegments,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Segment2D>& outImageSegments
)
```

Parameters

	Name	Type	Default	Description
➡	inWorldSegments	const Array<Segment2D>&		
➡	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
⬅	outImageSegments	Array<Segment2D>&		

WorldPlaneSegmentToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Segment.

Syntax

```
void avl::WorldPlaneSegmentToImage
(
 const avl::Segment2D& inWorldSegment,
 const avl::RectificationTransform& inTransform,
 avl::Segment2D& outImageSegment
)
```

Parameters

	Name	Type	Default	Description
→	inWorldSegment	const Segment2D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageSegment	Segment2D&		

WorldPlaneStripesToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Stripes.

Syntax

```
void avl::WorldPlaneStripesToImage
(
 const atl::Array<avl::Stripe1D>& inWorldStripes,
 const avl::RectificationTransform& inTransform,
 atl::Array<avl::Stripe1D>& outImageStripes
)
```

Parameters

	Name	Type	Default	Description
→	inWorldStripes	const Array<Stripe1D>&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageStripes	Array<Stripe1D>&		

WorldPlaneStripeToImage

Header: AVL.h
Namespace: avl
Module: Calibration

Finds the image coordinates of world plane Stripe.

Syntax

```
void avl::WorldPlaneStripeToImage
(
 const avl::Stripe1D& inWorldStripe,
 const avl::RectificationTransform& inTransform,
 avl::Stripe1D& outImageStripe
)
```

Parameters

	Name	Type	Default	Description
→	inWorldStripe	const Stripe1D&		
→	inTransform	const RectificationTransform&		Transform's camera model is needed for applying distortion back. Transform's homography is needed for transforming coordinates back from a given world plane.
←	outImageStripe	Stripe1D&

AppendPointToPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Appends a point to a path.

Syntax

```
void avl::AppendPointToPath
(
 avl::Path& ioPath,
 const avl::Point2D& inPoint
)
```

Parameters

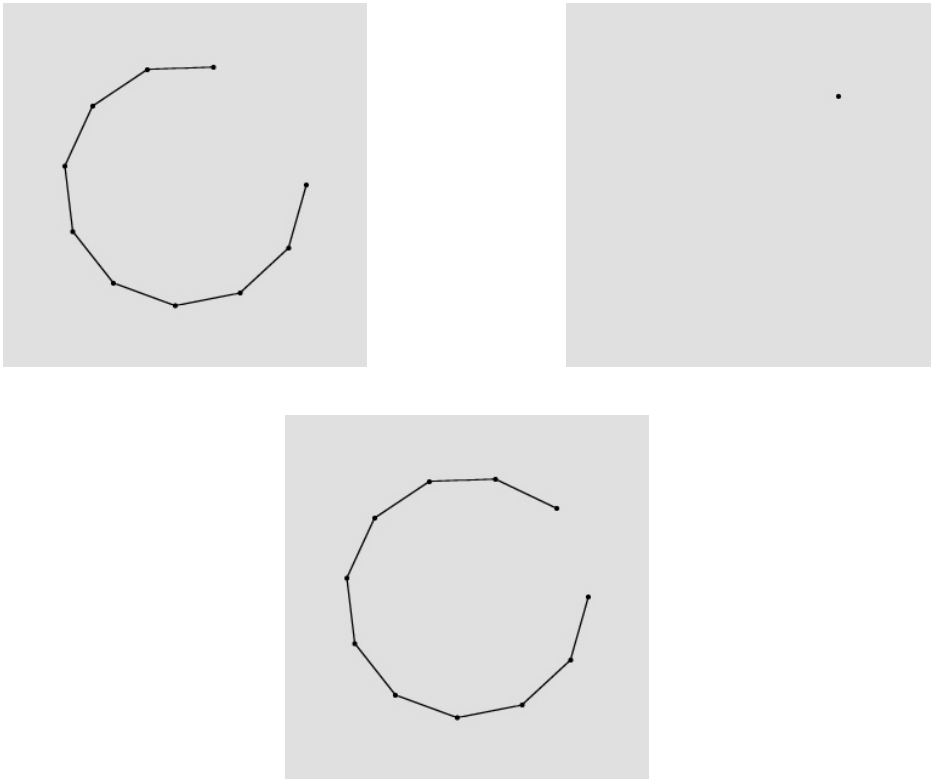
	Name	Type	Default	Description
	ioPath	Path&		
	inPoint	const Point2D&		Input point

Description

The operation extends an open path by adding a single point at its end (the point becomes new end point of a path).

When a closed path is passed to the filter, an error with appropriate description occurs.

Examples



AppendPointToPath *run on sample path and point.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Closed path on input in AppendPointToPath.

See Also

- ConcatenatePaths – Joins up to four open paths.

ClosePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adds the segment connecting the last point with the first one in a path.

Syntax

```
void avl::ClosePath
(
 avl::Path& ioPath
)
```

Parameters

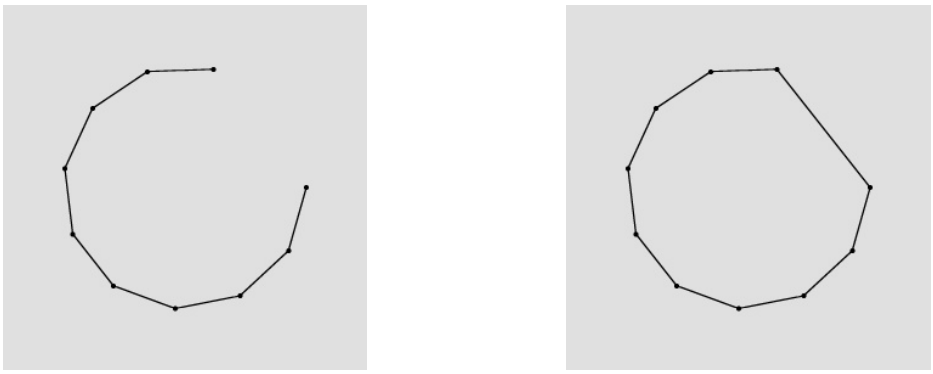
	Name	Type	Default	Description
	ioPath	Path&		

Description

The operation extends an open path by adding a segment between its first point and the last one, therefore producing a closed path.

If a closed path is passed, the filter passes it onto output without any interference.

Examples



***ClosePath** run on a sample path.*

See Also

- OpenPath – Removes the segment connecting the last point with the first one in a path.

CreateArcPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an open path containing cocircular, equidistant points.

Syntax

```
void avl::CreateArcPath
(
 const avl::Arc2D& inArc,
 int inPointCount,
 avl::Path& outPath
)
```

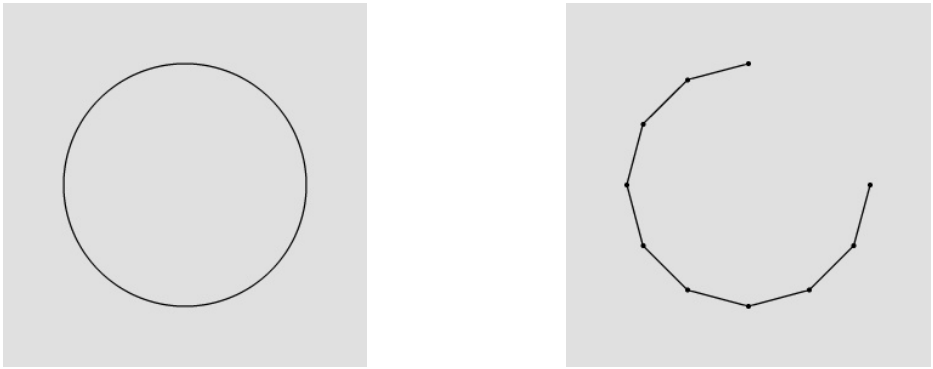
Parameters

	Name	Type	Range	Default	Description
→	inArc	const Arc2D&			
→	inPointCount	int	2 – ∞	8	Number of points in the resulting path
←	outPath	Path&			Output path

Description

The operation produces an open path that consists of **inPointCount** equidistant points selected along the **inArc** arc.

Examples



***CreateArcPath** run using a sample arc with **inPointCount** = 10.*

See Also

- CreateSegmentPath – Creates an open path containing collinear, equidistant points.
- CreateCirclePath – Creates a closed path containing cocircular, equidistant points.

CreateCirclePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a closed path containing cocircular, equidistant points.

Syntax

```
void avl::CreateCirclePath
(
 const avl::Circle2D& inCircle,
 int inPointCount,
 avl::Path& outPath
)
```

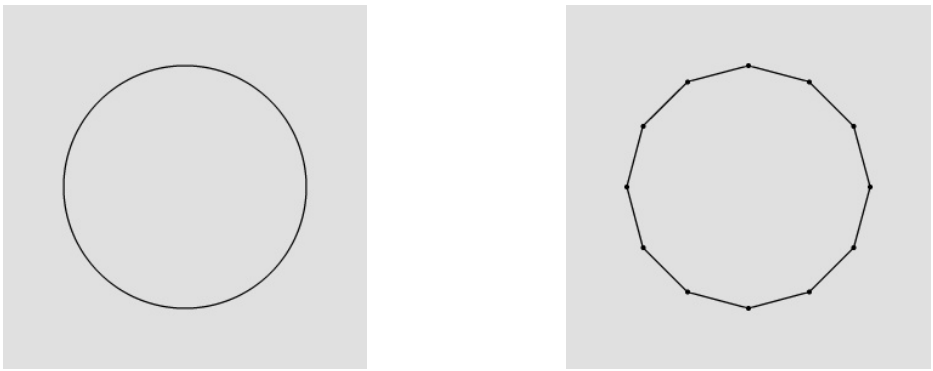
Parameters

	Name	Type	Range	Default	Description
→	inCircle	const Circle2D&			
→	inPointCount	int	2 – ∞	8	Number of points in the resulting path
←	outPath	Path&			Output path

Description

The operation produces a closed path that consist of **inPointCount** equidistant points selected along the **inCircle** circumference.

Examples



***CreateCirclePath** run using a sample circle with **inPointCount** = 12.*

See Also

- CreateSegmentPath – Creates an open path containing collinear, equidistant points.
- CreateArcPath – Creates an open path containing cocircular, equidistant points.

Also in AVL Lite

CreateEllipsePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a closed path containing elliptical, equidistant points.

Syntax

```
void avl::CreateEllipsePath
(
 const avl::Point2D& inCenter,
 float inRadiusX,
 float inRadiusY,
 int inPointCount,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCenter	const Point2D&			
→	inRadiusX	float	0.0 – ∞		
→	inRadiusY	float	0.0 – ∞		
→	inPointCount	int	2 – ∞	8	Number of points in the resulting path
←	outPath	Path&			Output path

Also in AVL Lite

CreateRectanglePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a closed path containing four vertices of rectangle.

Syntax

```
void avl::CreateRectanglePath
(
 const avl::Rectangle2D& inRectangle,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outPath	Path&		Output path

CreateSegmentPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an open path containing collinear, equidistant points.

Syntax

```
void avl::CreateSegmentPath
(
 const avl::Point2D& inBegin,
 const avl::Point2D& inEnd,
 int inPointCount,
 avl::Path& outPath
)
```

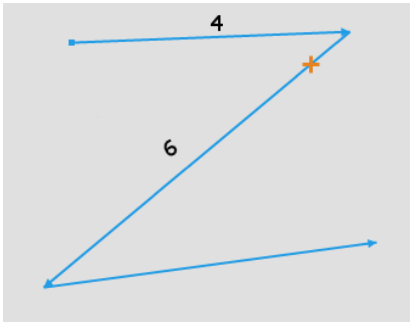
Parameters

	Name	Type	Range	Default	Description
→	inBegin	const Point2D&			First point of the path
→	inEnd	const Point2D&			Last point of the path
→	inPointCount	int	2 – ∞	2	Number of points in the created path
←	outPath	Path&			Output path

Description

The operation produces an open path that consist of **inPointCount** equidistant points selected along the segment between **inBegin** and **inEnd**.

Examples



***CreateSegmentPath** run with **inPointCount** = 5.*

See Also

- CreateArcPath – Creates an open path containing cocircular, equidistant points.
- CreateCirclePath – Creates a closed path containing cocircular, equidistant points.

Also in AVL Lite

GetPathCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the selected characteristic point of a path.

Syntax

```
void avl::GetPathCharacteristicPoint
(
 const avl::Path& inPath,
 int inIndex,
 const bool inInverse,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inIndex	int	0 – ∞		Index of a point of the input path
→	inInverse	const bool			Reversed order of points
←	outPoint	Point2D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Index out of range in GetPathCharacteristicPoint.

Also in AVL Lite

GetPathCharacteristicPoint_Interpolated

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns linear interpolation between two consecutive characteristic points of a path.

Syntax

```
void avl::GetPathCharacteristicPoint_Interpolated
(
 const avl::Path& inPath,
 float inIndex,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inIndex	float	0.0 – ∞		Real-valued point index; fractional values result in interpolation
←	outPoint	Point2D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Index out of range in GetPathCharacteristicPoint_Interpolated.

GetPathSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the selected segment of a path.

Syntax

```
void avl::GetPathSegment
(
 const avl::Path& inPath,
 int inIndex,
 const bool inInverse,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inIndex	int	0 – ∞		
→	inInverse	const bool			Reversed order of segments
←	outSegment	Segment2D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path in GetPathSegment.
DomainError	Incorrect segment index in GetPathSegment.

GetPointOnPath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a path point of desired distance (measured along path) from the first point of the path.

Syntax

```
void avl::GetPointOnPath
(
 const avl::Path& inPath,
 const float inDistanceAlongPath,
 avl::Point2D& outPoint
)
```

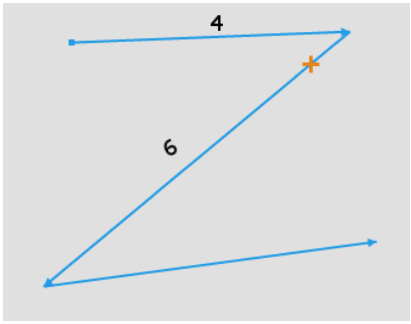
Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inDistanceAlongPath	const float	0.0 – ∞		Distance along path from the first characteristic point to the desired point
←	outPoint	Point2D&			

Description

Returns a path point of desired distance (measured along path) from the first point of the path.

Examples



Point with a distance of 5 from path origin.

Errors

List of possible exceptions:

Error type	Description
DomainError	Desired distance along path exceeds the path length in GetPointOnPath.

InsertToPath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Inserts a new point to a path at a specified location.

Syntax

```
void avl::InsertToPath
(
 avl::Path& ioPath,
 const avl::Point2D& inPoint,
 int inIndex,
 bool inInverse
)
```

Parameters

	Name	Type	Range	Default	Description
	ioPath	Path&			
	inPoint	const Point2D&			Input point to be inserted.
	inIndex	int	0 – ∞		Input index within the ioPath at which the inValue will be placed.
	inInverse	bool		False	Determines if the indices are counted from beginning or from end of the input path.

Errors

List of possible exceptions:

Error type	Description
DomainError	Index out of range in InsertToPath.

OpenPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes the segment connecting the last point with the first one in a path.

Syntax

```
void avl::OpenPath
(
 avl::Path& ioPath
)
```

Parameters

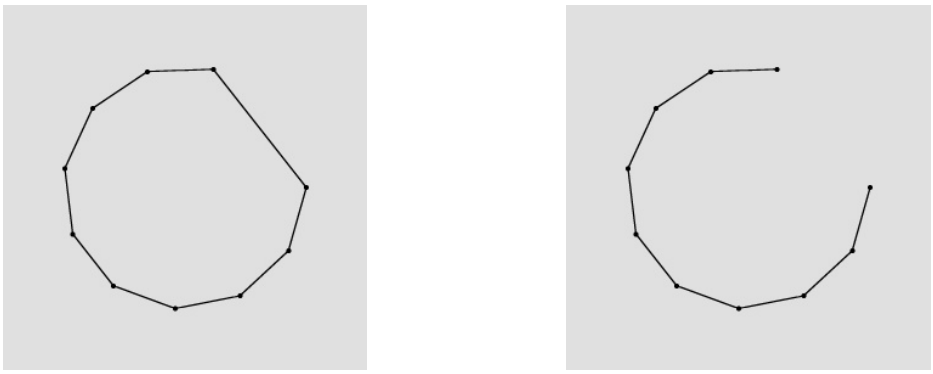
	Name	Type	Default	Description
	ioPath	Path&		

Description

The operation reduces a closed path by removing a segment between its first point and the last one, therefore producing an open path.

If an open path is passed, the filter passes it onto output without any interference.

Examples



***OpenPath** run on a sample path.*

See Also

- ClosePath – Adds the segment connecting the last point with the first one in a path.

RemovePointFromPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes a point from a path.

Syntax

```
void avl::RemovePointFromPath
(
 avl::Path& ioPath,
 int inIndex,
 bool inInverse
)
```

Parameters

	Name	Type	Default	Description
	ioPath	Path&		
	inIndex	int		
	inInverse	bool		

Errors

List of possible exceptions:

Error type	Description
DomainError	Index out of range in RemovePointFromPath.

Also in AVL Lite

SetPathCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Modifies the value of a selected characteristic point.

Syntax

```
void avl::SetPathCharacteristicPoint
(
 avl::Path& ioPath,
 int inIndex,
 const bool inInverse,
 const avl::Point2D& inPoint
)
```

Parameters

	Name	Type	Range	Default	Description
	ioPath	Path&			
	inIndex	int	0 – ∞		Index of a point of the input path
	inInverse	const bool			Reversed order of points
	inPoint	const Point2D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Index out of range in SetPathCharacteristicPoint.

Also in AVL Lite

SkipEmptyPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

If the input path has at least one point, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty paths, e.g. just before the PathBoundingBox filter is to be invoked.

Syntax

```
void avl::SkipEmptyPath
(
 const avl::Path& inPath,
 atl::Conditional<avl::Path>& outNotEmptyPath,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outNotEmptyPath	Conditional<Path>&		A copy of the input path, if it is not empty, or Nil otherwise
←	outIsNotEmpty	bool&		Indication if the input path is not empty

Also in AVL Lite

SkipNotPolygon

Header: AVL.h
Namespace: avl
Module: FoundationLite

If the input path is closed and has no self-intersections, then it is copied to the output; otherwise Nil is returned.

Syntax

```
void avl::SkipNotPolygon
(
 const avl::Path& inPath,
 atl::Conditional<avl::Path>& outPolygon,
 bool& outIsPolygon
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outPolygon	Conditional<Path>&		
←	outIsPolygon	bool&		

Subpath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an open path from a continuous subsequence of the input path's points.

Syntax

```
void avl::Subpath
(
 const avl::Path& inPath,
 const int inStart,
 const int inPointCount,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inStart	const int	0 – ∞		Index of the first point of the subpath
→	inPointCount	const int	0 – ∞	1	Number of points in the subpath
←	outPath	Path&			The resulting subpath

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect index range on input in Subpath.

36. Principal Component Analysis

Table of content:

- ApplyPCATransform
- CreatePCATransform
- MatrixDeterminant
- MatrixPseudoEigenvectors
- NormalizeMatrixData
- ReversePCATransform

ApplyPCATransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Applies previously obtained Principal Component Analysis (PCA) transformation coefficients to new data.

Syntax

```
void avl::ApplyPCATransform
(
 const avl::Matrix& inMatrix,
 const avl::PCAModel& inPCAModel,
 avl::Matrix& outTransformedMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		Input data with variables in columns and examples in rows.
→	inPCAModel	const PCAModel&		Previously created PCA model to apply to data provided in inMatrix.
←	outTransformedMatrix	Matrix&		Transformed inMatrix.

Errors

List of possible exceptions:

Error type	Description
DomainError	Malformed inPCAModel – MeanVector and StandardDeviationVector are not row-vectors in ApplyPCATransform.
DomainError	Malformed inPCAModel – MeanVector and StandardDeviationVector have to have the same length in ApplyPCATransform.
DomainError	PCAModel does not match – inMatrix column count does not match in ApplyPCATransform.
DomainError	PCAModel does not match – PCAFeatureVector dimensions does not correspond to inMatrix dimensions in ApplyPCATransform.
DomainError	PCAModel does not match – StandardDeviationVector length is different then inMatrix column count in ApplyPCATransform.

CreatePCATransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Performs the Principal Component Analysis (PCA) on provided data, creates the feature vector and normalization coefficients (mean and standard deviation of variables).

Syntax

```
void avl::CreatePCATransform
(
 const avl::Matrix& inMatrix,
 const int inDimensions,
 atl::Optional<float> inVarianceToLeave,
 avl::PCAModel& outPCAModel,
 avl::Matrix& outTransformedMatrix,
 avl::Matrix& diagCovarianceMatrix,
 avl::Matrix& diagNormalizedData,
 atl::Array<int>& diagUsedFeatureIndices
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMatrix	const Matrix&			Input data, where variables are in column, and examples are in rows.
→	inDimensions	const int	1 – ∞		How many data dimensions (variables) to be left in transformed data.
→	inVarianceToLeave	Optional<float>	0.0 – 1.0	0.95f	How many of input data variance should be left in transformed data; overrides inDimensions input.
←	outPCAModel	PCAModel&			Resulting PCA model.
←	outTransformedMatrix	Matrix&			Transformed inMatrix with reduced dimensionality.
🔍	diagCovarianceMatrix	Matrix&			Covariance matrix of input data.
🔍	diagNormalizedData	Matrix&			Input data after normalization: scaling and centering.
🔍	diagUsedFeatureIndices	Array<int>&			Indices of columns in inMatrix, which were used as Principal Components.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot conduct PCA on empty matrix in CreatePCATransform.
DomainError	Cannot conduct principal component analysis for 1-row data set in CreatePCATransform.
DomainError	Cannot reduce data to less than 1 dimension in CreatePCATransform.
DomainError	Could not compute eigenvalues and/or eigenvectors in CreatePCATransform.
DomainError	inDimensions has to be lesser then inMatrix column count in PCA filter in CreatePCATransform.
DomainError	The process did not converge in CreatePCATransform.
DomainError	The provided data did not satisfy the prerequisites in CreatePCATransform.

MatrixDeterminant

Header: AVL.h
Namespace: avl
Module: FoundationPro

Find the determinant of a square matrix.

Syntax

```
void avl::MatrixDeterminant
(
 const avl::Matrix& inMatrix,
 float& outDeterminant
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
←	outDeterminant	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty matrix in MatrixDeterminant.
DomainError	Matrix dimensions incompatible in MatrixDeterminant.

MatrixPseudoEigenvectors

Header: AVL.h
Namespace: avl
Module: FoundationPro

Find the pseudo-eigenvalues and pseudo-eigenvectors of a symmetrical square matrix.

Syntax

```
void avl::MatrixPseudoEigenvectors
(
 const avl::Matrix& inMatrix,
 avl::Matrix& outEigenvectors,
 atl::Array<float>& outEigenvalues
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
←	outEigenvectors	Matrix&		Row matrix of eigenvectors
←	outEigenvalues	Array<float>&		Array of eigenvalues

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix empty on input in MatrixPseudoEigenvectors!
DomainError	Matrix with non-matching dimensions on input in MatrixPseudoEigenvectors!

NormalizeMatrixData

Header: AVL.h
Namespace: avl
Module: FoundationPro

Treats Matrix as a data frame, where examples are in rows while columns represent features, and normalizes the data by subtracting mean from each column and dividing it by its standard deviation.

Syntax

```
void avl::NormalizeMatrixData
(
 const avl::Matrix& inMatrix,
 atl::Optional<const avl::Matrix&> inMeansVector,
 atl::Optional<const avl::Matrix&> inStandardDeviationsVector,
 avl::Matrix& outNormalizedMatrix,
 avl::Matrix& outMeansVector,
 avl::Matrix& outStandardDeviationsVector
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		Input data frame.
→	inMeansVector	Optional<const Matrix&>	NIL	If provided, will be used in normalization of inMatrix.
→	inStandardDeviationsVector	Optional<const Matrix&>	NIL	If provided, will be used in normalization of inMatrix.
←	outNormalizedMatrix	Matrix&		Resulting normalized matrix.
←	outMeansVector	Matrix&		Resulting Means vector - copy of inMeansVector, or calculated Means, if inMeansVector was set NIL.
←	outStandardDeviationsVector	Matrix&		Resulting StdDevs vector - copy of inStandardDeviationsVector, or calculated Means, if inStandardDeviationsVector was set NIL.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect matrix dimensions in NormalizeData.
DomainError	One can provide both Means and StdDevs vector or none of them.

ReversePCATransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Reverses Principal Component Analysis (PCA) process. Can be used to transform data back to original feature space.

Syntax

```
void avl::ReversePCATransform
(
 const avl::Matrix& inTransformedMatrix,
 const avl::PCAModel& inPCAModel,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inTransformedMatrix	const Matrix&		Data that was transformed earlier.
→	inPCAModel	const PCAModel&		PCA model used to create inTransformedMatrix.
←	outMatrix	Matrix&		inTransformedMatrix transformed back to its original feature space.

Errors

List of possible exceptions:

Error type	Description
DomainError	Feature vector of inPCAModel and Transformed Data matrices dimensions do not correspond to each other in ReversePCATransform.
DomainError	inMeanVector and inStandardDeviationVector have incorrect size for inTransformedMatrix provided in ReversePCATransform.
DomainError	Malformed inPCAModel – StandardDeviationVector is not row-vector in ReversePCATransform.
DomainError	Malformed inPCAModel – MeanVector is not row-vector in ReversePCATransform.
DomainError	Malformed inPCAModel – uneven vector sizes in ReversePCATransform.

37. Image Look Up Tables

Table of content:

- ApplyPixelLut
- CreateCustomLut
- CreateGammaCorrectionLut
- CreateLogarithmLut
- CreatePowerLut

ApplyPixelLut

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Applies previously created Look Up transformation to provided image.

Syntax

```
void avl::ApplyPixelLut
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::PixelLut& inLut,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image to which LUT transformation will be applied
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inLut	const PixelLut&		LUT object, which defines transformation
←	outImage	Image&		Transformed image

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 2×uint8, 2×int8, 2×uint16, 2×int16, 3×uint8, 3×int8, 3×uint16, 3×int16, 4×uint8, 4×int8, 4×uint16, 4×int16.

Read more about pixel formats in Image documentation.

Description

This filter will apply previously created (by i.e. CreatePowerLut) LookUp Table transformation to **inImage**. Type and depth of resulting **outImage** are determined by properties of **inLut**, which were fixed during creation of LUT.

Generally speaking, LookUp transform should only be applied to monochromatic images. However, ApplyPixelLut allows for transformation of color images, under special conditions:

- **inLut** has to be created for single channel output
- **inImage** has to be multichannel (its depth has to be greater than 1)

If those conditions are met, processing steps are as follows: input image is being split into separate channels, every channel is processed by **inLut**, resulting processed channels are being merged into **outImage**.

It also possible to apply multichannel LUT to multichannel image, however number of channels (depth) must match, i.e. one can apply LUT of depth 3 to color, 3-channel image.

ApplyPixelLut can work with images of type: INT8, UINT8, INT16, UINT16, INT32, REAL. Operation time can be longer with INT32 and REAL, because LUT is not cached in this case - all calculations are performed during each execution, as opposed to cached execution, when only copying of appropriate values is conducted.

Remarks

Please note, that one cannot apply custom LUT created for INT32 and REAL types. This would result in storing enormous array of data in-memory and would not be feasible.

Standard operations like PowerImage, CorrectGamma and LogarithmImage for images of type Int32 and Real are available in Image Point Transforms category.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ApplyPixelLut.
DomainError	Not supported inImage pixel format in ApplyPixelLut. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 2xUInt8, 2xInt8, 2xUInt16, 2xInt16, 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 4xUInt8, 4xInt8, 4xUInt16, 4xInt16.

See Also

- ApplyPixelLut – Applies previously created Look Up transformation to provided image.
- CreatePowerLut – Creates Look Up Table for power operation on image pixels.
- CreateGammaCorrectionLut – Creates Look Up Table for gamma correction operation on image pixels.
- CreateLogarithmLut – Creates Look Up Table for logarithm operation on image pixels.

CreateCustomLut

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates Look Up Table for user provided operation on image pixels.

Syntax

```
void avl::CreateCustomLut
(
 const LutOperatorType& inLutFunction,
 const avl::PlainType::Type& inOutputType,
 atl::Optional<void*> inUserData,
 avl::PixelLut& outLut
)
```

Parameters

	Name	Type	Default	Description
→	inLutFunction	const LutOperatorType&		
→	inOutputType	const PlainType::Type&		
→	inUserData	Optional<void*>	NIL	Data passed as the second parameter to inLutFunction
←	outLut	PixelLut&		

Description

This function creates custom Look Up Table from function provided by user in form of callable.

Function to use can be passed as pointer to function, callable object (object with operator() defined) or lambda expression. Only requirement for such callable is for it to accept single parameter of type float and return value of type float.

Value passed to provided function is value of pixel. Value returned from provided function is value demanded from LUT being created.

CreateCustomLut will apply provided function on all possible values of **inOutputType** type and cache them in internal structure. Such PixelLut object can be then passed to ApplyPixelLut.

CreateCustomLut can create Look Up Tables for the following types: Int8, UInt8, Int16, UInt16.

Remarks

Standard operations like PowerImage, CorrectGamma and LogarithmImage for images of type Int32 and Real are available in Image Point Transforms category.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot create LUT with empty operator in CreateCustomLut.

See Also

- ApplyPixelLut – Applies previously created Look Up transformation to provided image.
- CreatePowerLut – Creates Look Up Table for power operation on image pixels.
- CreateGammaCorrectionLut – Creates Look Up Table for gamma correction operation on image pixels.
- CreateLogarithmLut – Creates Look Up Table for logarithm operation on image pixels.

CreateGammaCorrectionLut

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates Look Up Table for gamma correction operation on image pixels.

Syntax

```
void avl::CreateGammaCorrectionLut
(
 const float inValue,
 const avl::PlainType::Type& inOutputType,
 avl::PixelLut& outLut
)
```

Parameters

	Name	Type	Default	Description
→	inValue	const float	2.0f	
→	inOutputType	const PlainType::Type&		
←	outLut	PixelLut&		

Description

This operation will create LookUp Table with precalculated values of gamma correction on all pixel values of type defined in **inOutputType**. Such LUT can be reused across multiple ApplyPixelLut usages. This filter can create LUTs only for following types: INT8, UINT8, INT16, UINT16.

Remarks

Standard operations like PowerImage, CorrectGamma and LogarithmImage for images of type Int32 and Real are available in Image Point Transforms category.

See Also

- ApplyPixelLut – Applies previously created Look Up transformation to provided image.
- CreatePowerLut – Creates Look Up Table for power operation on image pixels.

- CorrectGamma – Performs gamma correction.

CreateLogarithmLut

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates Look Up Table for logarithm operation on image pixels.

Syntax

```
void avl::CreateLogarithmLut
(
 atl::Optional<const float&> inScale,
 float inOffset,
 bool inNormalizeZero,
 const avl::PlainType::Type& inOutputType,
 avl::PixelLut& outLut
)
```

Parameters

	Name	Type	Default	Description
→	inScale	Optional<const float&>	NIL	Scaling factor (default: 255)
→	inOffset	float		Offset factor
→	inNormalizeZero	bool		Specifies whether the output range should be rescaled to start from 0
→	inOutputType	const PlainType::Type&		
←	outLut	PixelLut&		

Description

This operation will create LookUp Table with precalculated values of logarithm operation on all pixel values of type defined in **inOutputType**. Such LUT can be reused across multiple ApplyPixelLut usages. This filter can create LUTs only for following types: INT8, UINT8, INT16, UINT16.

Remarks

Standard operations like PowerImage, CorrectGamma and LogarithmImage for images of type Int32 and Real are available in Image Point Transforms category.

- CreateLogarithmLut – Creates Look Up Table for logarithm operation on image pixels.
- LogarithmImage – Computes a natural logarithm of each pixel.

CreatePowerLut

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates Look Up Table for power operation on image pixels.

Syntax

```
void avl::CreatePowerLut
(
 float inValue,
 const avl::PlainType::Type& inOutputType,
 avl::PixelLut& outLut
)
```

Parameters

	Name	Type	Default	Description
→	inValue	float	2.0f	
→	inOutputType	const PlainType::Type&		
←	outLut	PixelLut&		

Description

This operation will create LookUp Table with precalculated values of power operation on all pixel values of type defined in **inOutputType**. Such LUT can be reused across multiple ApplyPixelLut usages. This filter can create LUTs only for following types: INT8, UINT8, INT16, UINT16.

Remarks

Standard operations like PowerImage, CorrectGamma and LogarithmImage for images of type Int32 and Real are available in Image Point Transforms category.

ArcCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the circle containing an arc.

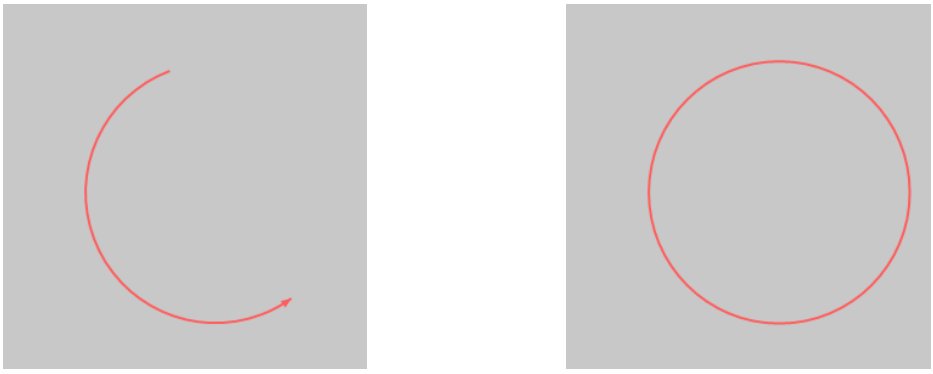
Syntax

```
void avl::ArcCircle
(
 const avl::Arc2D& inArc,
 avl::Circle2D& outCircle
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		Input arc
←	outCircle	Circle2D&		Circle containing the arc

Examples



ArcCircle *performed on the sample arc.*

ArcEndpoints

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes two endpoints of an arc.

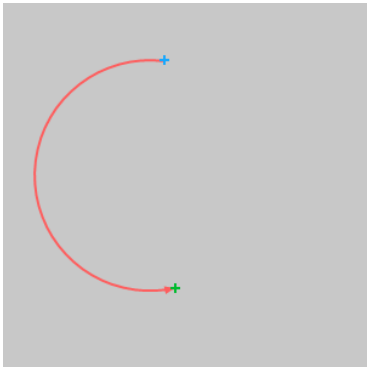
Syntax

```
void avl::ArcEndpoints
(
 const avl::Arc2D& inArc,
 avl::Point2D& outPoint1,
 avl::Point2D& outPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		
←	outPoint1	Point2D&		First endpoint
←	outPoint2	Point2D&		Second endpoint

Examples



*The resulting **outPoint1**(blue) and **outPoint2**(green) drawn with the input arc.*

ArcLength

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the length of an arc.

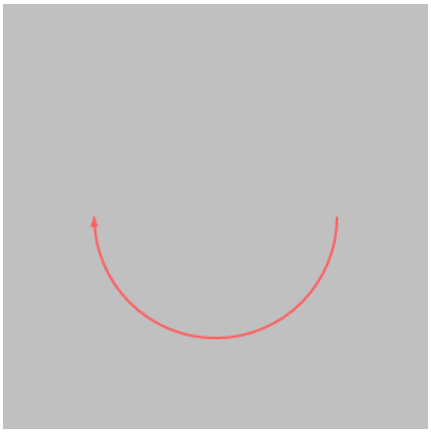
Syntax

```
void avl::ArcLength
(
 const avl::Arc2D& inArc,
 float& outLength
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		
←	outLength	float&		

Examples



__ArcLength__ performed on an arc with parameters: __X__ = 175, __Y__ = 175, __Radius__ = 100, __StartAngle__ = 0, __SweepAngle__ = 180.
The __outLength__ returns a value of __314,159__.

ArcMidpoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the midpoint of an arc.

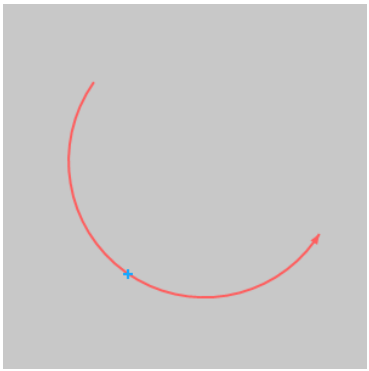
Syntax

```
void avl::ArcMidpoint
(
 const avl::Arc2D& inArc,
 avl::Point2D& outMidpoint
)
```

Parameters

	Name	Type	Default	Description
→	inArc	const Arc2D&		
←	outMidpoint	Point2D&		

Examples



*The resulting **outMidpoint** drawn with the input arc.*

CircleArea

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the area of a circle.

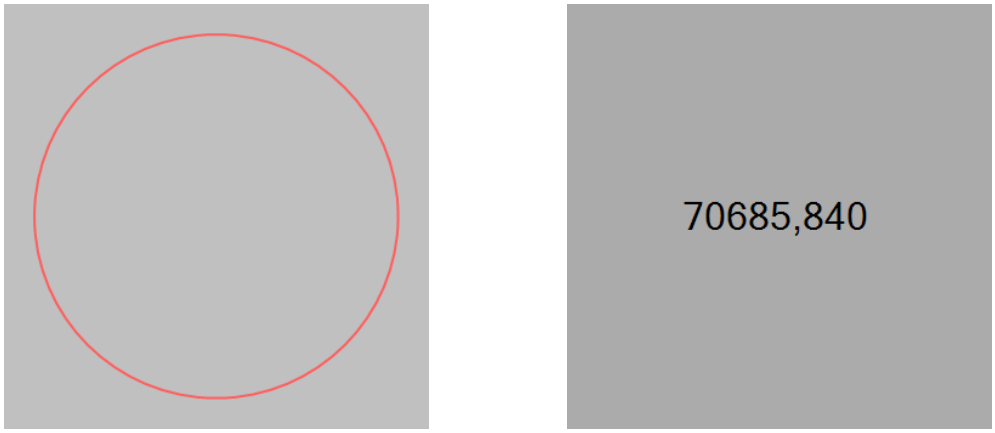
Syntax

```
void avl::CircleArea
(
 const avl::Circle2D& inCircle,
 float& outArea
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outArea	float&		

Examples



__CircleArea__ performed on a circle with parameters: __X__ = 175, __Y__ = 175, __Radius__ = 150. The __outArea__ returns a value of __70685,84__.

CircleBoundingBox

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a circle.

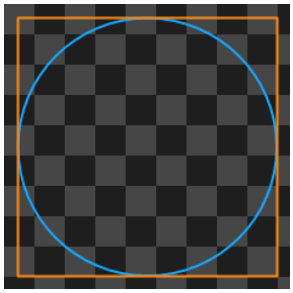
Syntax

```
void avl::CircleBoundingBox
(
 const avl::Circle2D& inCircle,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outBoundingBox	Box&		

Examples



CircleBoundingBox performed on a sample circle.

CircleBoundingRectangle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle containing a circle.

Syntax

```
void avl::CircleBoundingRectangle
(
 const avl::Circle2D& inCircle,
 atl::Optional<float> inAngle,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

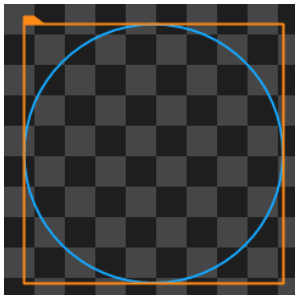
	Name	Type	Default	Description
→	inCircle	const Circle2D&		Input circle
→	inAngle	Optional<float>	NIL	Expected angle of the resulting rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input circle
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Examples



CircleBoundingRectangle performed on a sample circle.

CircleCharacteristicPoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a characteristic point (e.g. the top-left) of a box containing the input circle.

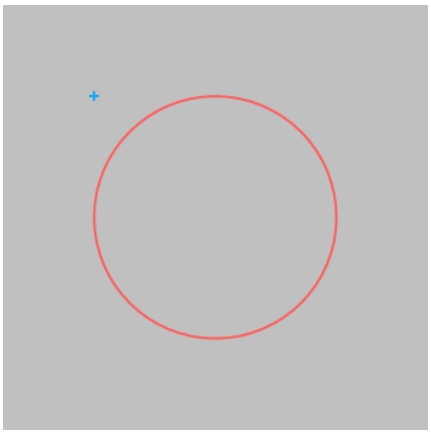
Syntax

```
void avl::CircleCharacteristicPoint
(
 const avl::Circle2D& inCircle,
 const avl::Anchor2D::Type inPointAnchor,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inPointAnchor	const Anchor2D::Type	TopLeft	
←	outPoint	Point2D&		

Examples



CircleCharacteristicPoint *performed on a circle with* ***inPointAnchor*** *= TopLeft.*

CirclePerimeterLength

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the length of a circle perimeter.

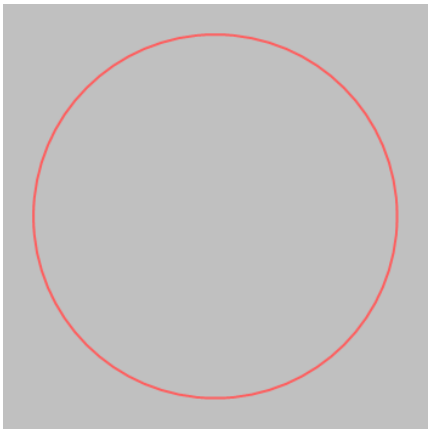
Syntax

```
void avl::CirclePerimeterLength
(
 const avl::Circle2D& inCircle,
 float& outPerimeterLength
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
←	outPerimeterLength	float&		

Examples



CirclePerimeterLength *performed on a circle with parameters:* ***X*** *= 175,* ***Y*** *= 175,* ***Radius*** *= 150.*
The ***outPerimeterLength*** *returns a value of* ***942,478****.*

Also in AVL Lite

CircleSection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes an arciform section of the circle perimeter.

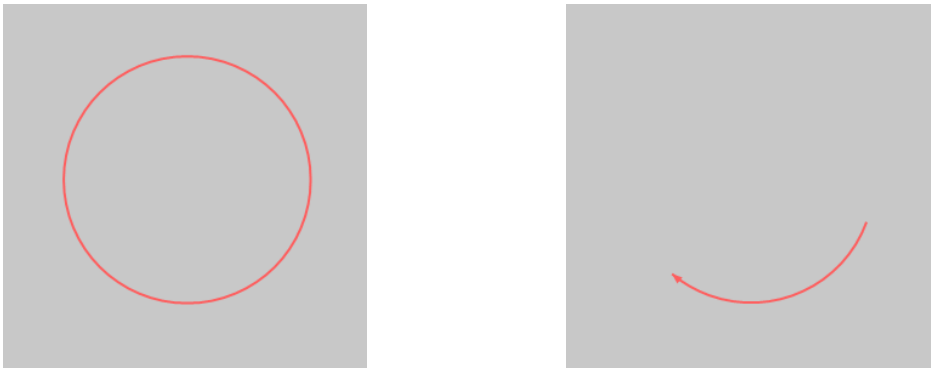
Syntax

```
void avl::CircleSection
(
 const avl::Circle2D& inCircle,
 float inStartAngle,
 float inSweepAngle,
 avl::Arc2D& outArc
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		Input circle
→	inStartAngle	float		Direction at which the arc begins
→	inSweepAngle	float		Angular length of the arc (may be negative)
←	outArc	Arc2D&		

Examples



CircleSection *performed on the sample circle,* ***inStartAngle*** *= 20.0 and* ***inSweepAngle*** *= 110.0.*

Also in AVL Lite

EllipseArea

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the area of an ellipse.

Syntax

```
void avl::EllipseArea
(
 const avl::Ellipse2D& inEllipse,
 float& outArea
)
```

Parameters

	Name	Type	Default	Description
→	inEllipse	const Ellipse2D&		
←	outArea	float&		

EllipseBoundingBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing an ellipse.

Syntax

```
void avl::EllipseBoundingBox
(
 const avl::Ellipse2D& inEllipse,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
➡	inEllipse	const Ellipse2D&		
⬅	outBoundingBox	Box&		

Also in AVL Lite

EllipseBoundingRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle containing an ellipse.

Syntax

```
void avl::EllipseBoundingRectangle
(
 const avl::Ellipse2D& inEllipse,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
➡	inEllipse	const Ellipse2D&		
⬅	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input points
⬅	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
⬅	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
⬅	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

EllipseBoundingRectangle_FixedAngle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle with the given orientation angle containing an ellipse.

Syntax

```
void avl::EllipseBoundingRectangle_FixedAngle
(
 const avl::Ellipse2D& inEllipse,
 float inAngle,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inEllipse	const Ellipse2D&		
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input ellipse
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

LineNormalVector

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the normal vector of a line.

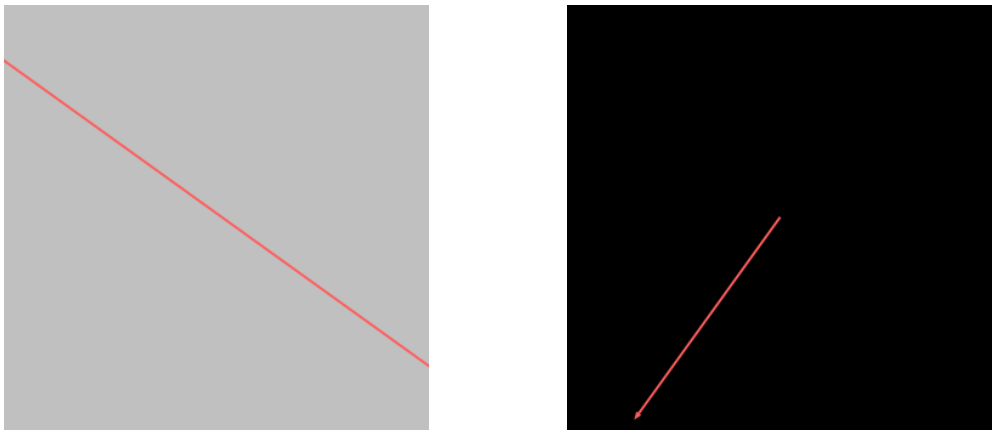
Syntax

```
void avl::LineNormalVector
(
 const avl::Line2D& inLine,
 bool inReverse,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inReverse	bool	True	
←	outVector	Vector2D&		

Examples



LineNormalVector *performed on a line (left image) returns* ***outVector*** *(right image).*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LineNormalVector.

LineOrientation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the orientation angle of a line as angle in the range from 0 to 180.

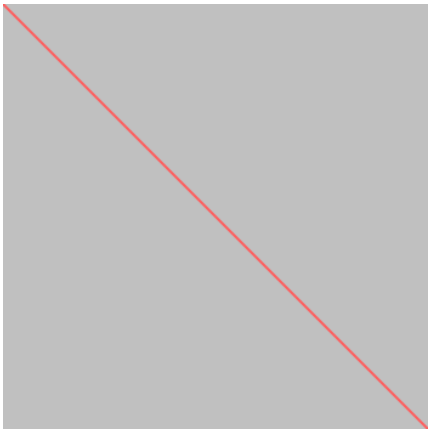
Syntax

```
void avl::LineOrientation
(
 const avl::Line2D& inLine,
 float& outOrientationAngle
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
←	outOrientationAngle	float&		

Examples



LineOrientation *performed on a line.*
The ***outOrientationAngle*** *in this case returns a value of* ***45****.*

PointsBoundingBox

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing an array of points.

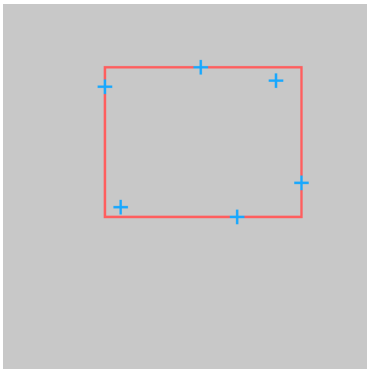
Syntax

```
void avl::PointsBoundingBox
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outBoundingBox	Box&		

Examples



*The resulting **outBoundingBox** drawn with the input points.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in PointsBoundingBox.

PointsBoundingBox_OrNil

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing an array of points; returns NIL if the array is empty.

Syntax

```
void avl::PointsBoundingBox_OrNil
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Conditional<avl::Box>& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outBoundingBox	Conditional<Box>&		

PointsBoundingCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle containing an array of points.

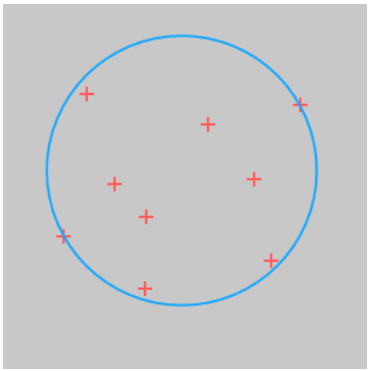
Syntax

```
void avl::PointsBoundingCircle
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::Circle2D& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outBoundingCircle	Circle2D&		

Examples



*The resulting **outBoundingCircle** drawn with the input points.*

PointsBoundingCircle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle containing an array of points; returns NIL if the array is empty.

Syntax

```
void avl::PointsBoundingCircle_OrNil
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Conditional<avl::Circle2D>& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outBoundingCircle	Conditional<Circle2D>&		

PointsBoundingEllipse

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest ellipse containing an array of points if such ellipse exists.

Syntax

```
void avl::PointsBoundingEllipse
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::Ellipse2D& outBoundingEllipse,
 atl::Array<avl::Point2D>& outBoundaryPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outBoundingEllipse	Ellipse2D&		
←	outBoundaryPoints	Array<Point2D>&		

PointsBoundingParallelogram

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the smallest parallelogram containing an array of points.

Syntax

```
void avl::PointsBoundingParallelogram
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::BoundingRectangleFeature::Type inBoundingParallelogramFeature,
 avl::Path& outBoundingParallelogram,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL,
 atl::Optional<float&> outAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
→	inBoundingParallelogramFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding parallelogram will be computed
←	outBoundingParallelogram	Path&		Smallest bounding parallelogram of the input points
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding parallelogram
←	outLongSide	Optional<float&>	NIL	Length of the bounding parallelogram long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding parallelogram short side
←	outAngle	Optional<float&>	NIL	Angle of the bounding parallelogram

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**, **outAngle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No points on input in PointsBoundingParallelogram.
DomainError	Unknown parallelogram feature in PointsBoundingParallelogram.

Also in AVL Lite

PointsBoundingRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle containing an array of points.

Syntax

```
void avl::PointsBoundingRectangle
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input points
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

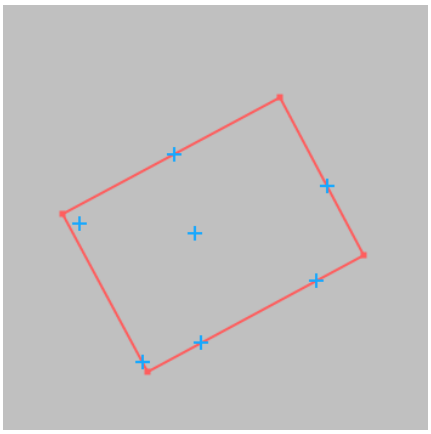
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Description

The filter computes a rectangle with the smallest possible selected feature that contains all given points. The angle of the resulting rectangle is then normalized as in the NormalizeRectangleOrientation filter.

Examples



*The resulting **outBoundingRectangle** drawn with the input points and with **inRectangleOrientation** set on **Horizontal***

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect BoundingRectangleFeature in PointsBoundingRectangle.
DomainError	No points on input in PointsBoundingRectangle.

See Also

- NormalizeRectangleOrientation – Changes orientation of the given rectangle according to parameters.

PointsBoundingRectangle_FixedAngle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle with the given orientation angle containing an array of points.

Syntax

```
void avl::PointsBoundingRectangle_FixedAngle
(
 const atl::Array<avl::Point2D>& inPoints,
 float inAngle,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input points
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in PointsBoundingRectangle_FixedAngle.

PointsBoundingRectangle_FixedAngle_OrNil

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle with the given orientation angle containing an array of points; returns NIL when the array is empty.

Syntax

```
void avl::PointsBoundingRectangle_FixedAngle_OrNil
(
 const atl::Array<avl::Point2D>& inPoints,
 float inAngle,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input points
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

PointsBoundingRectangle_OrNil

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest rectangle containing an array of points; returns NIL when the array is empty.

Syntax

```
void avl::PointsBoundingRectangle_OrNil
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input points
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

PointsCaliperDiameter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the longest and the shortest width of the input points measured as distance between parallel lines containing all of them.

Syntax

```
void avl::PointsCaliperDiameter
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<avl::Segment2D&> outMinDiameter = atl::NIL,
 atl::Optional<float&> outMinDiameterLength = atl::NIL,
 atl::Optional<avl::Segment2D&> outMaxDiameter = atl::NIL,
 atl::Optional<float&> outMaxDiameterLength = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outMinDiameter	Optional<Segment2D&>	NIL	
←	outMinDiameterLength	Optional<float&>	NIL	
←	outMaxDiameter	Optional<Segment2D&>	NIL	
←	outMaxDiameterLength	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinDiameter**, **outMinDiameterLength**, **outMaxDiameter**, **outMaxDiameterLength**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty point array on input in PointsCaliperDiameter.

PointsConvexHull

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest convex shape that contains the given array of points.

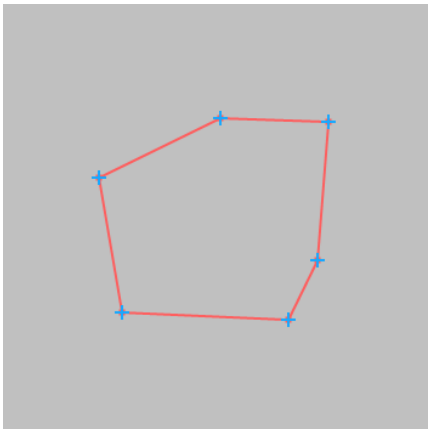
Syntax

```
void avl::PointsConvexHull
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::Path& outConvexHull
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outConvexHull	Path&		A closed path representing the computed convex hull

Examples



*The resulting **outConvexHull** drawn with the input points.*

PointsDiameter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Finds the longest segment connecting two points from a given array.

Syntax

```
void avl::PointsDiameter
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<avl::Segment2D&> outDiameter = atl::NIL,
 atl::Optional<float&> outDiameterLength = atl::NIL
)
```

Parameters

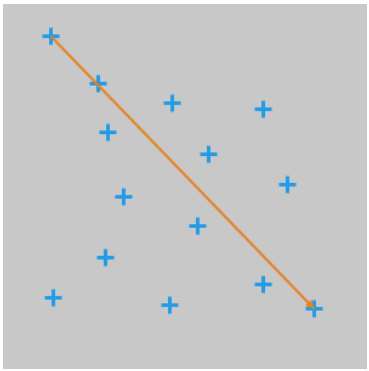
	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Input array of points
←	outDiameter	Optional<Segment2D&>	NIL	Longest segment found
←	outDiameterLength	Optional<float&>	NIL	Length of longest segment found

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDiameter**, **outDiameterLength**.

Read more about Optional Outputs.

Examples



PointsDiameter *performed on an array of input points. The orange line is the result.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points on input in PointsDiameter.

PointsMassCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the central point of the input points.

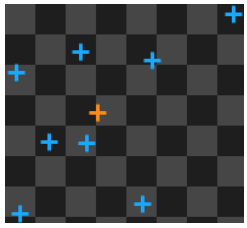
Syntax

```
void avl::PointsMassCenter
(
 const atl::Array<avl::Point2D>& inPoints,
 avl::Point2D& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outMassCenter	Point2D&		

Examples



PointsMassCenter *performed on a set of 8 input points. The orange point is the result.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in PointsMassCenter.

PointsMassCenter_OrNil

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the central point of the input points; returns NIL if the array is empty.

Syntax

```
void avl::PointsMassCenter_OrNil
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Conditional<avl::Point2D>& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outMassCenter	Conditional<Point2D>&		

PointsMedian

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the geometric median of the input points.

Syntax

```
void avl::PointsMedian
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Optional<const atl::Array<float>&> inWeights,
 const int inMaxIterationCount,
 avl::Point2D& outGeometricMedian,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Array<avl::Point2D>& diagApproximationSteps = atl::Dummy<atl::Array<Point2D> >()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inWeights	Optional<const Array<float>&>		NIL	Optional input weights
→	inMaxIterationCount	const int	1 – ∞	10	Maximum number of iterations
←	outGeometricMedian	Point2D&			Geometric median
←	outDistanceSum	Optional<float&>		NIL	Sum of distances from input points to geometric median
🔍	diagApproximationSteps	Array<Point2D>&			Approximate geometric medians calculated during subsequent iterations

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input arrays must be of the same size in PointsMedian.
DomainError	Input point array is empty in PointsMedian.

PointsOrientation

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the orientation of a set of 2D points.

Syntax

```
void avl::PointsOrientation
(
 const atl::Array<avl::Point2D>& inPoints,
 float& outOrientation
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outOrientation	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points on input in PointsOrientation.

RectangleArea

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the area of a rectangle.

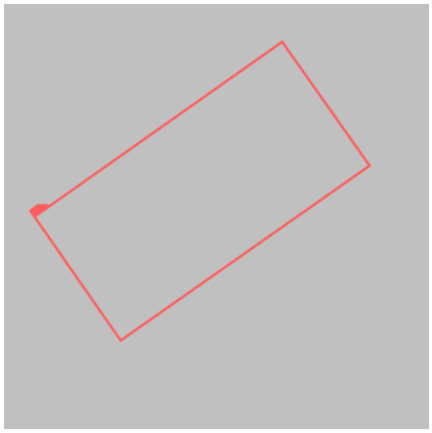
Syntax

```
void avl::RectangleArea
(
 const avl::Rectangle2D& inRectangle,
 float& outArea
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outArea	float&		

Examples



RectangleArea *performed on a rectangle with parameters:* ***X*** *= 25,* ***Y*** *= 175,* ***Angle*** *= 325,* ***Width*** *= 250,* ***Height*** *= 125. The* ***outArea*** *returns a value of* ***31250****.*

RectangleBoundingBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a rectangle.

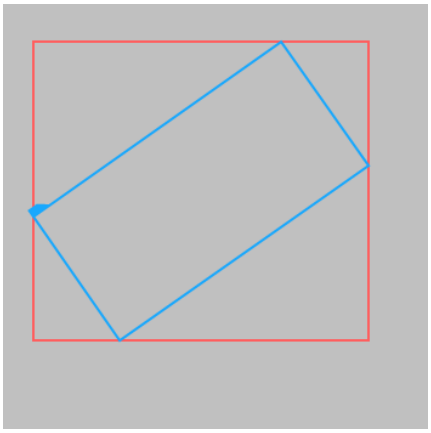
Syntax

```
void avl::RectangleBoundingBox
(
 const avl::Rectangle2D& inRectangle,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outBoundingBox	Box&		

Examples



RectangleBoundingBox *performed on a rectangle (blue) with parameters:* ***X*** *= 25,* ***Y*** *= 175,* ***Angle*** *= 325,* ***Width*** *= 250,* ***Height*** *= 125.*
The result (red box) is returned in ***outBoundingBox****.*

Also in AVL Lite

RectangleBoundingCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest circle containing a rectangle.

Syntax

```
void avl::RectangleBoundingCircle
(
 const avl::Rectangle2D& inRectangle,
 avl::Circle2D& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outBoundingCircle	Circle2D&		

RectangleCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the center point of a rectangle.

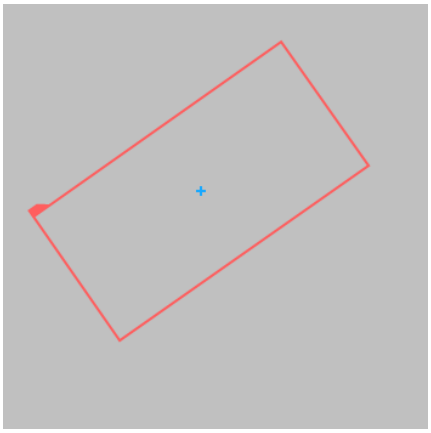
Syntax

```
void avl::RectangleCenter
(
 const avl::Rectangle2D& inRectangle,
 avl::Point2D& outCenterPoint
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outCenterPoint	Point2D&		

Examples



RectangleCenter *performed on a rectangle with parameters:* ***X*** *= 25,* ***Y*** *= 175,* ***Angle*** *= 325,* ***Width*** *= 250,* ***Height*** *= 125.*
The center point is returned in ***outCenterPoint****.*

RectangleCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a characteristic point (e.g. the top-left) of the input rectangle.

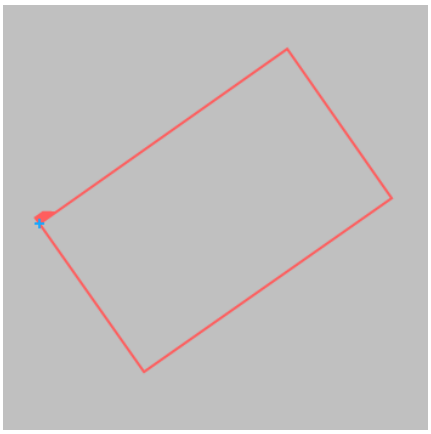
Syntax

```
void avl::RectangleCharacteristicPoint
(
 const avl::Rectangle2D& inRectangle,
 const avl::Anchor2D::Type inPointAnchor,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inPointAnchor	const Anchor2D::Type	TopLeft	
←	outPoint	Point2D&		

Examples



RectangleCharacteristicPoint *performed on a rectangle with* ***inPointAnchor*** *= TopLeft.*

RectangleCharacteristicPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes rectangle's characteristic points.

Syntax

```
void avl::RectangleCharacteristicPoints
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<avl::Point2D&> outTopLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outTopCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outTopRight = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleRight = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomRight = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outCorners = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outTopLeft	Optional<Point2D&>	NIL	
←	outTopCenter	Optional<Point2D&>	NIL	
←	outTopRight	Optional<Point2D&>	NIL	
←	outMiddleLeft	Optional<Point2D&>	NIL	
←	outMiddleCenter	Optional<Point2D&>	NIL	
←	outMiddleRight	Optional<Point2D&>	NIL	
←	outBottomLeft	Optional<Point2D&>	NIL	
←	outBottomCenter	Optional<Point2D&>	NIL	
←	outBottomRight	Optional<Point2D&>	NIL	
←	outCorners	Optional<Array<Point2D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTopLeft**, **outTopCenter**, **outTopRight**, **outMiddleLeft**, **outMiddleCenter**, **outMiddleRight**, **outBottomLeft**, **outBottomCenter**, **outBottomRight**, **outCorners**.

Read more about Optional Outputs.

RectangleCorners

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the four corner points of a rectangle.

Syntax

```
void avl::RectangleCorners
(
 const avl::Rectangle2D& inRectangle,
 avl::Point2D& outTopLeft,
 avl::Point2D& outTopRight,
 avl::Point2D& outBottomRight,
 avl::Point2D& outBottomLeft
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outTopLeft	Point2D&		
←	outTopRight	Point2D&		
←	outBottomRight	Point2D&		
←	outBottomLeft	Point2D&		

RectanglePerimeterLength

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the perimeter length of a rectangle.

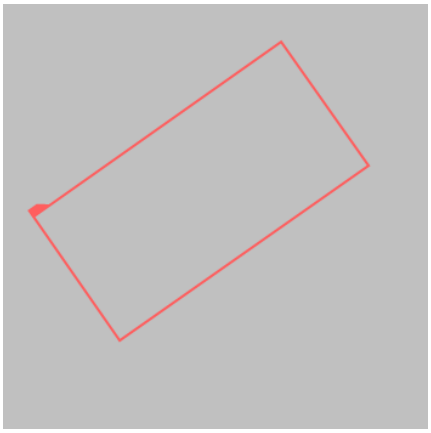
Syntax

```
void avl::RectanglePerimeterLength
(
 const avl::Rectangle2D& inRectangle,
 float& outPerimeterLength
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outPerimeterLength	float&		

Examples



RectanglePerimeterLength *performed on a rectangle with parameters:* ***X*** *= 25,* ***Y*** *= 175,* ***Angle*** *= 325,* ***Width*** *= 250,* ***Height*** *= 125.*
The ***outPerimeterLength*** *returns a value of* ***750****.*

RectangleSides

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns segments representing the sides of the input rectangle.

Syntax

```
void avl::RectangleSides
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<avl::Segment2D&> outTopSide = atl::NIL,
 atl::Optional<avl::Segment2D&> outRightSide = atl::NIL,
 atl::Optional<avl::Segment2D&> outBottomSide = atl::NIL,
 atl::Optional<avl::Segment2D&> outLeftSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
←	outTopSide	Optional<Segment2D&>	NIL	
←	outRightSide	Optional<Segment2D&>	NIL	
←	outBottomSide	Optional<Segment2D&>	NIL	
←	outLeftSide	Optional<Segment2D&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTopSide**, **outRightSide**, **outBottomSide**, **outLeftSide**.

Read more about Optional Outputs.

SegmentBisector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a line passing through the center of a segment at a right angle.

Syntax

```
void avl::SegmentBisector
(
 const avl::Segment2D& inSegment,
 avl::Line2D& outBisector
)
```

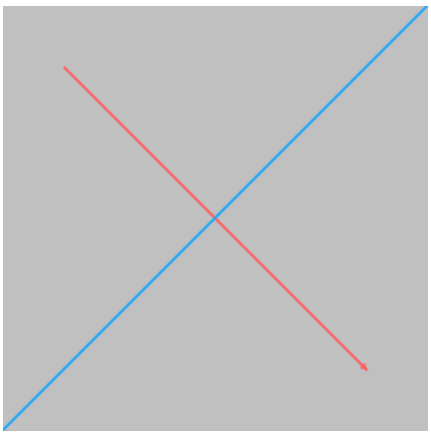
Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outBisector	Line2D&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an empty segment is given on input.

Examples



SegmentBisector *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.*

SegmentCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the center point of a segment.

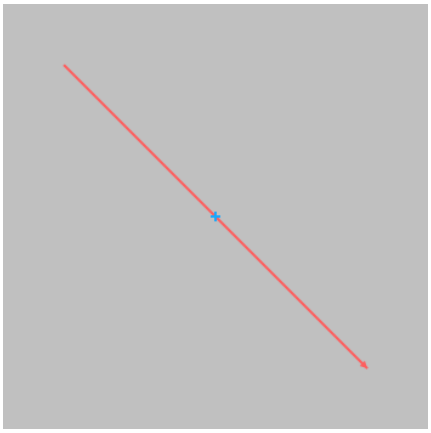
Syntax

```
void avl::SegmentCenter
(
 const avl::Segment2D& inSegment,
 avl::Point2D& outCenterPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outCenterPoint	Point2D&		

Examples



SegmentCenter *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.*

SegmentLength

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the length of a segment.

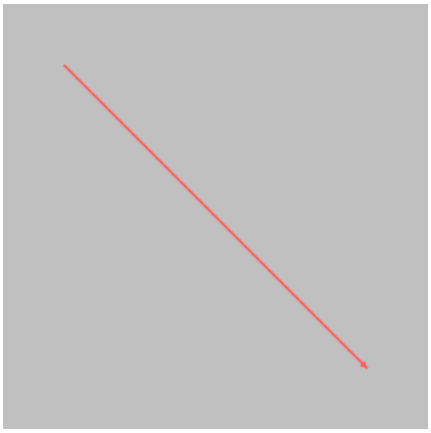
Syntax

```
void avl::SegmentLength
(
 const avl::Segment2D& inSegment,
 float& outLength
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outLength	float&		

Examples



SegmentLength *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.*
outLength *returns* ***353,553****.*

SegmentLine

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the line passing through a segment.

Syntax

```
void avl::SegmentLine
(
 const avl::Segment2D& inSegment,
 avl::Line2D& outLine
)
```

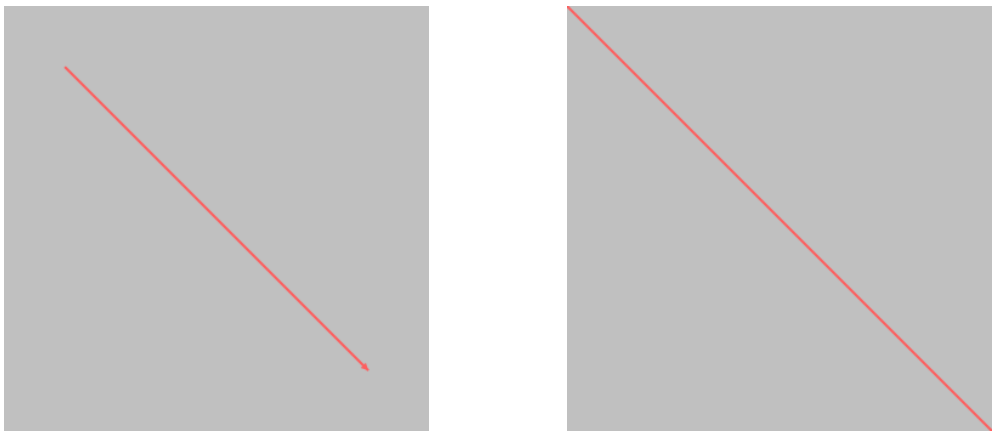
Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		Input segment
←	outLine	Line2D&		The resulting line

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an empty segment is given on input.

Examples



SegmentLine *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.* ***outLine*** *returns line (picture on right).*

SegmentNormalVector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes an unitary vector perpendicular to the segment.

Syntax

```
void avl::SegmentNormalVector
(
 const avl::Segment2D& inSegment,
 bool inReverse,
 avl::Vector2D& outNormalVector
)
```

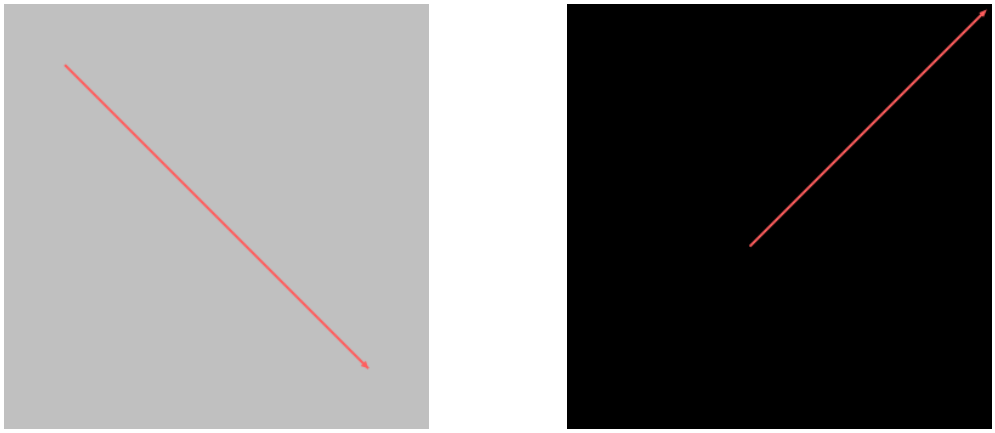
Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inReverse	bool	True	
←	outNormalVector	Vector2D&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an empty segment is given on input.

Examples



SegmentNormalVector *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.*
outNormalVector *result shown on the right picture.*

SegmentOrientation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the orientation of a segment.

Syntax

```
void avl::SegmentOrientation
(
 const avl::Segment2D& inSegment,
 avl::AngleRange::Type inAngleRange,
 float& outOrientationAngle
)
```

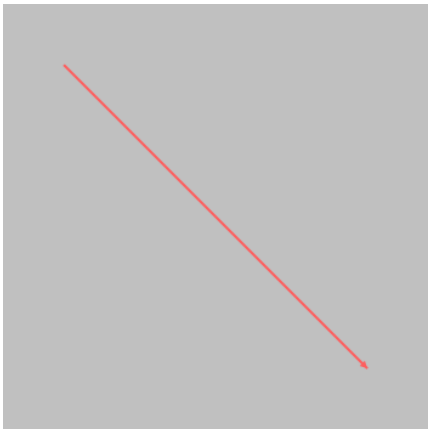
Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inAngleRange	AngleRange::Type	_0_180	Switches between 0-90, 0-180 or 0-360 degrees
←	outOrientationAngle	float&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an empty segment is given on input.

Examples



SegmentOrientation *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300 and* ***inAngleRange*** *set to _0_180.*
outOrientationAngle *returns* ***45****.*

SegmentVector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the vector [x2 - x1, y2 - y1].

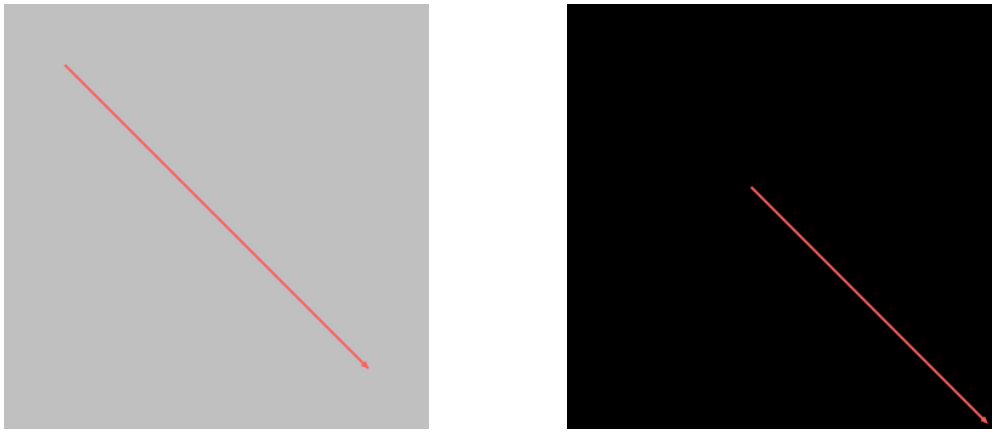
Syntax

```
void avl::SegmentVector
(
 const avl::Segment2D& inSegment,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
←	outVector	Vector2D&		

Examples



SegmentVector *performed on a segment with parameters:* ***X1*** *= 50,* ***Y1*** *= 50,* ***X2*** *= 300,* ***Y2*** *= 300.*
outVector *result shown on the right picture.*

VectorDirection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the direction angle of a vector as an angle in range the from 0 to 360.

Syntax

```
void avl::VectorDirection
(
 const avl::Vector2D& inVector,
 float& outDirection
)
```

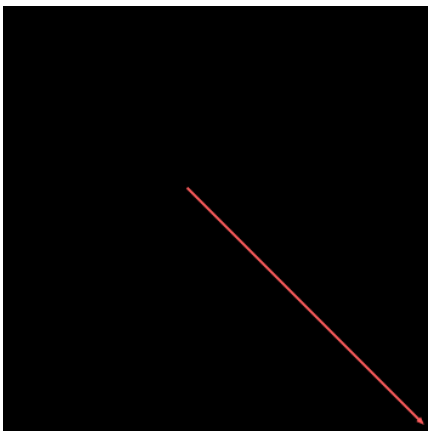
Parameters

	Name	Type	Default	Description
→	inVector	const Vector2D&		
←	outDirection	float&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when a zero vector is given on input.

Examples



VectorDirection *performed on a vector with parameters:* ***DeltaX*** *= 10,* ***DeltaY*** *= 10.*
outDirection *returns* ***45****.*

VectorLength

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the length of a vector.

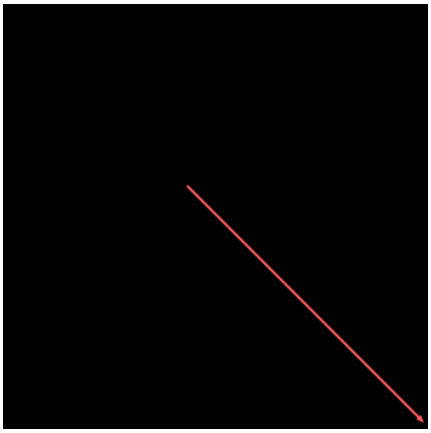
Syntax

```
void avl::VectorLength
(
 const avl::Vector2D& inVector,
 float& outLength
)
```

Parameters

	Name	Type	Default	Description
→	inVector	const Vector2D&		
←	outLength	float&		

Examples



VectorLength *performed on a vector with parameters:* ***DeltaX*** *= 10,* ***DeltaY*** *= 10.*
outLength *returns* ***14,142****.*

VectorsMedian

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the geometric median of the input vectors.

Syntax

```
void avl::VectorsMedian
(
 const atl::Array<avl::Vector2D>& inVectors,
 atl::Optional<const atl::Array<float>&> inWeights,
 const int inMaxIterationCount,
 avl::Vector2D& outGeometricMedian,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Array<avl::Vector2D>& diagApproximationSteps = atl::Dummy<atl::Array<Vector2D> >()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVectors	const Array<Vector2D>&			Input vectors
→	inWeights	Optional<const Array<float>&>		NIL	Optional input weights
→	inMaxIterationCount	const int	1 – ∞	10	Maximum number of iterations
←	outGeometricMedian	Vector2D&			Geometric median
←	outDistanceSum	Optional<float&>		NIL	Sum of distances from input vectors to geometric median
🔍	diagApproximationSteps	Array<Vector2D>&			Approximate geometric medians calculated during subsequent iterations

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input arrays must be of the same size in VectorsMedian.
DomainError	Input vector array is empty in VectorsMedian.

39. Assertions

Table of content:

- AssertImageEqualTo

AssertImageEqualTo

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Asserts that two images are equal or differ by a small given margin.

Syntax

```
void avl::AssertImageEqualTo
(
 const avl::Image& inImage,
 const avl::Image& inExpectedImage,
 const float inMaxDifference,
 const atl::String& inDescription,
 const float inEpsilon = 1.0f,
 const int inEpsilonScale = -6
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inExpectedImage	const Image&			
➡	inMaxDifference	const float	0.0 – ∞	0.0f	Maximum absolute difference between a specific pixel of the two images
➡	inDescription	const String&			
➡	inEpsilon	const float	0.0 – ∞	1.0f	Maximum allowed difference, significant. InEpsilon will be multiplied by 10^inEpsilonScale before checking the difference
➡	inEpsilonScale	const int		-6	

Errors

List of possible exceptions:

Error type	Description
DomainError	Input images have different pixel formats in AssertImageEqualTo.
DomainError	Input images have different sizes in AssertImageEqualTo.

40. Image Enhancement

Table of content:

- AutoAdjustColors
- EqualizeImageHistogram
- ExpaintImage_Bornemann
- ExpaintImage_Telea
- InpaintImage
- InpaintImage_Bornemann
- InpaintImage_Telea
- NormalizeImage
- NormalizeLocalBrightness_Gauss
- NormalizeLocalBrightness_Mean
- NormalizeLocalContrast
- SharpenImage

AutoAdjustColors

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Adjusts image colors by stretching each channel separately.

Syntax

```
void avl::AutoAdjustColors
(
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in AutoAdjustColors. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

EqualizeImageHistogram

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Maps image pixels to new values to achieve uniform distribution of intensities in the range (0, 255).

Syntax

```
void avl::EqualizeImageHistogram
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inSaturateBrightestFraction,
 float inSaturateDarkestFraction,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inSaturateBrightestFraction	float	0.0 – 1.0	0.0f	Fraction of the brightest pixels skipped during normalization
→	inSaturateDarkestFraction	float	0.0 – 1.0	0.0f	Fraction of the darkest pixels skipped during normalization
←	outImage	Image&			Output image

Requirements

For input **inImage** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

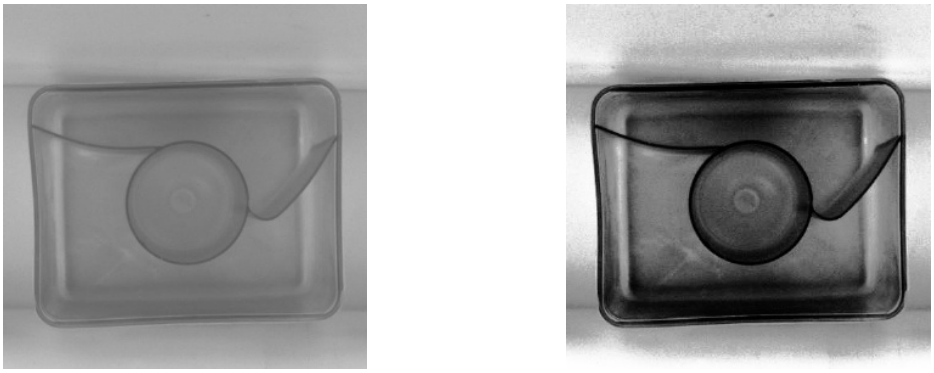
Description

The filter applies non-linear mapping to image pixel values so that pixel intensities of the resulting image are evenly distributed in range from 0 to 255.

The operation computes the cumulative histogram c of **inImage** and the image size N. Then the result is computed as follows:

$$outImage[i,j] = C[inImage[i,j]] \times \frac{255}{N}$$

Examples



EqualizeImageHistogram *run on example image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in EqualizeImageHistogram.
DomainError	The sum of inSaturateBrightestFraction and inSaturateDarkestFraction can't be greater than 1 in EqualizeImageHistogram.
DomainError	Not supported inImage pixel format in EqualizeImageHistogram. Supported formats: 1xUInt8.

See Also

- ImageHistogram – Computes the histogram of the image pixel values.
- ConvertToCumulativeHistogram – Computes the cumulative histogram of input histogram.

ExpaintImage_Bornemann

Header: AVL.h
Namespace: avl
Module: FoundationPro

Speculatively sets pixel values outside of a region using the fast marching method and coherence analysis.

Syntax

```
void avl::ExpaintImage_Bornemann
(
 const avl::Image& inImage,
 const avl::Region& inRegionToExpaint,
 const int inExpaintingRadius,
 const int inRange,
 const float inPreSmoothing,
 const float inPostSmoothing,
 const float inSharpness,
 avl::LuminanceMode::Type inLuminanceMode,
 avl::Image& outImage
)
```

Parameters

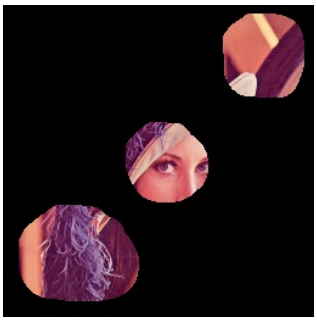
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRegionToExpaint	const Region&			Part of the image to be expainted
→	inExpaintingRadius	const int	1 – +∞	8	How far to expaint from the region
→	inRange	const int	1 – +∞	6	Defines how far a pixel can be from one currently being inpainted to be considered in calculations
→	inPreSmoothing	const float	0.0 – ∞	2.0f	Standard deviation of a gaussian kernel used before inpainting calculations
→	inPostSmoothing	const float	0.0 – ∞	3.0f	Standard deviation of a gaussian kernel used after initial inpainting calculations
→	inSharpness	const float	0.0 – ∞	35.0f	Desired sharpness of edges inside of the inpainted region (higher = sharper)
→	inLuminanceMode	LuminanceMode::Type		YUV	Determines how the luminance of the input image will be computed
←	outImage	Image&			Output image

Description

This filter expaints a region of an image by **inExpaintingRadius** pixels using the fast marching method and coherence flow analysis.

A detailed description of this method can be found here: InpaintImage_Bornemann.

Examples



Input image

*From the left: output with **inRange** = 4, output with **inRange** = 12*

*From the left: output with **inPreSmoothing** = 1, output with **inPreSmoothing** = 3*

*From the left: output with **inPostSmoothing** = 1, output with **inPostSmoothing** = 6*

*From the left: output with **inSharpness** = 25, output with **inSharpness** = 100*

Errors

List of possible exceptions:

Error type	Description
DomainError	Expainting region (inRegionToExpaint) exceeds the image in ExpaintImage_Bornemann.
DomainError	No pixels available at the edge of inRegionToExpaint in ExpaintImage_Bornemann.

ExpaintImage_Telea

Header: AVL.h
Namespace: avl
Module: FoundationPro

Speculatively sets pixel values outside of a region using the fast marching method.

Syntax

```
void avl::ExpaintImage_Telea
(
 const avl::Image& inImage,
 const avl::Region& inRegionToExpaint,
 const int inExpaintingRadius,
 const int inRange,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRegionToExpaint	const Region&			Part of the image to be expainted
→	inExpaintingRadius	const int	1 – +∞	8	How far to expaint from the region
→	inRange	const int	1 – +∞	6	Defines how far a pixel can be from one currently being inpainted to be considered in calculations
←	outImage	Image&			Output image

Description

This filter expaints a region of an image by **inExpaintingRadius** pixels using the fast marching method. It is a simper version of ExpaintImage_Bornemann.

Examples

*Comparison between low and high values of **inRange**. From the left: input, output with **inRange** = 4, output with **inRange** = 12*

Errors

List of possible exceptions:

Error type	Description
DomainError	Expainting region (inRegionToExpaint) exceeds the image in ExpaintImage_Telea.
DomainError	No pixels available at the edge of inRegionToExpaint in ExpaintImage_Telea.

InpaintImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Fills in a region of an image with pixel values interpolated from the borders of the area.

Applications: Speculative setting of unknown (or unwanted) pixels. Usually used for preparing incomplete images for further processing.

Syntax

```
void avl::InpaintImage
(
 avl::Image& ioImage,
 float inLambda,
 const avl::ShapeRegion& inRegionToInpaint,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment
)
```

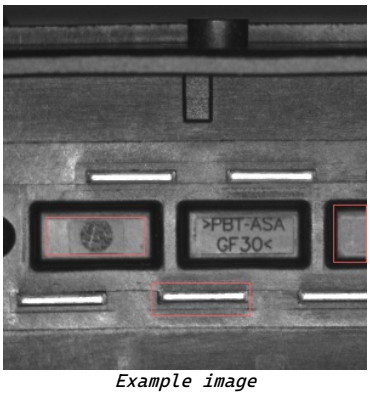
Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inLambda	float	0.0 – 1.0	0.5f	Ratio between vertical and horizontal interpolation
	inRegionToInpaint	const ShapeRegion&			Region to be inpainted
	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region

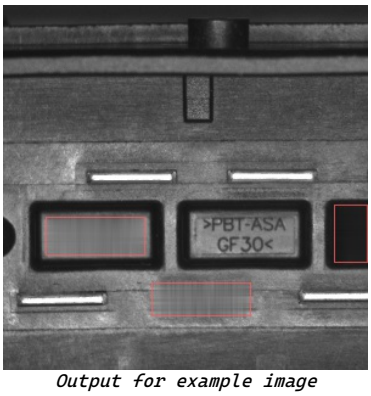
Description

The filter fills in the region (**inRegionToInpaint**) within the image (**inImage**) using the color of the surrounding (external border) of the region. The value of the pixel is a weighted average of horizontal and vertical linear interpolation, where the weight is defined by the parameter **inLambda**.
Thus it is a weighted average of four pixels: the closest pixel of the remaining image in four directions, where the weight is reversed distance between pixels times the parameter (which is *inLambda* for the upper and lower and *1.0-inLambda* for the left and right pixels). In case one of those points doesn't exist, it's just omitted in averaging. If none of the point exist, the color is zero.

Examples



Example image



Output for example image

Remarks

It works well when the image around the region is "uniform" in the sense that the (external) border of the region is smooth. If not, the interpolated surface is striped/chequered.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in InpaintImage.

InpaintImage_Bornemann

Header: AVL.h
Namespace: avl
Module: FoundationPro

Fills in a region of an image with pixel values interpolated from the borders of the area; uses fast marching method and coherence analysis.

Applications: Speculative setting of unknown (or unwanted) pixels. This version is giving the best results among reasonably fast traditional methods.

Syntax

```
void avl::InpaintImage_Bornemann
(
 const avl::Image& inImage,
 const avl::Region& inRegionToInpaint,
 const int inRange,
 const float inPreSmoothing,
 const float inPostSmoothing,
 const float inSharpness,
 avl::LuminanceMode::Type inLuminanceMode,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRegionToInpaint	const Region&			
→	inRange	const int	1 – +∞	6	Defines how far a pixel can be from one currently being inpainted to be considered in calculations
→	inPreSmoothing	const float	0.0 – ∞	2.0f	Standard deviation of a gaussian kernel used before inpainting calculations
→	inPostSmoothing	const float	0.0 – ∞	3.0f	Standard deviation of a gaussian kernel used after initial inpainting calculations
→	inSharpness	const float	0.0 – ∞	35.0f	Desired sharpness of edges inside of the inpainted region (higher = sharper)
→	inLuminanceMode	LuminanceMode::Type		YUV	Determines how the luminance of the input image will be computed
←	outImage	Image&			Output image

Description

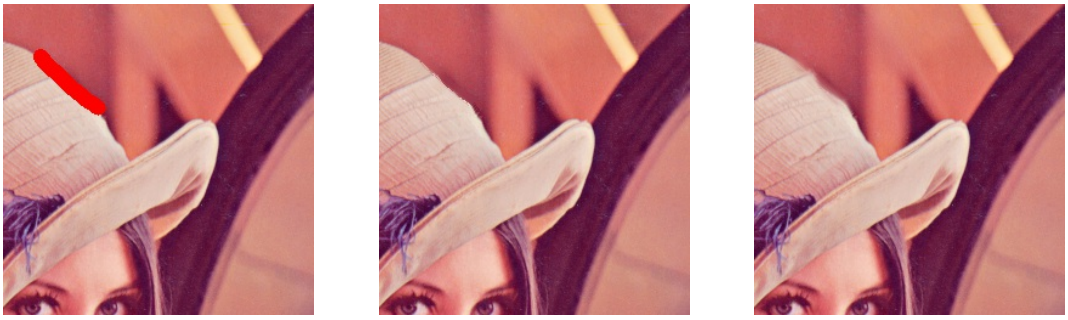
This filter inpaint a region of an image using the fast marching method and coherence flow analysis.

Each inpainted pixel is filled with a color calculated as a weighted average of all already known (i.e. those outside of the inpainting range or those that were already) pixels withing a range specified by the parameter **inRange**. Using a higher range will result in smoother edges withing the inpainted region. The calculation of the weights is done by analyzing the coherence flow of the input image which is previously smoothed with a gaussian kernel with the standard deviation given in **inPreSmoothing**. This means that lower values of this parameter will result in more detail being preserved but it may also introduce unwanted artifacts. After computing the coherence direction and strength, those values are also smoothed to allow for better preservation of angled edges. This smoothing is done using a kernel with the standard deviation given in **inPostSmoothing**. Higher values of this parameter higher quality estimation of angles within the inpainted region but it will also increase the work time of this filter. Additionally one can specify how important the coherence flow information is by using the **inSharpness** parameter (Setting **inSharpness** to zero will mean that coherence information is to be ignored). Higher values will stress the importance of preserving the structure of the inpainted image and will result in sharper edges.

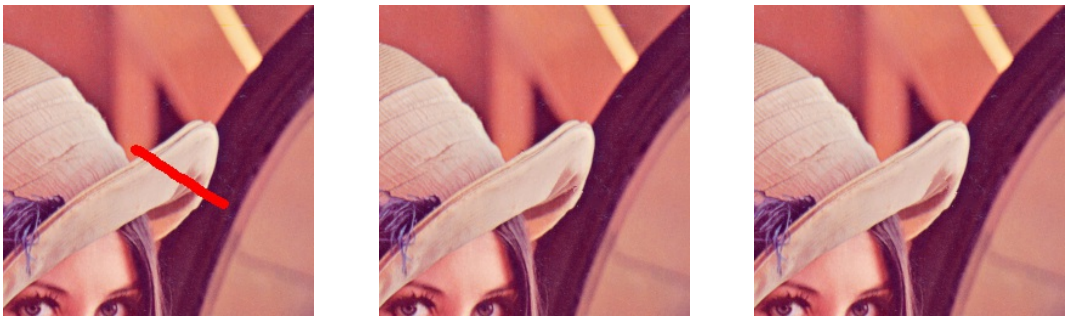
Hints

- To preserve color information of 3-channel images in a way that is more suited for a human eye, set **inLuminanceMode** to YUV.
- Sometimes higher values of **inPreSmoothing** are needed to filter out noise that might interfere with coherence direction calculations.
- Increasing **inSharpness** can help prevent blurred edges withing the inpainting region.
- If round edges are expected withing the inpainting region, high values of **inPostSmoothing** are recommended.

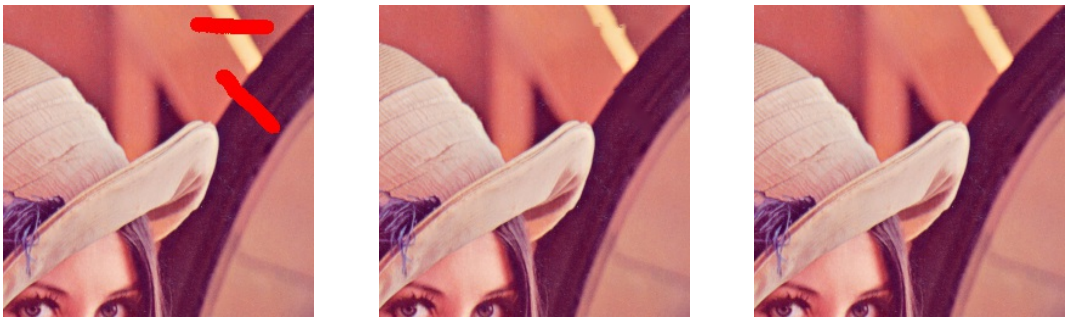
Examples



*Comparison between low and high values of **inRange**. From the left: input, output with **inRange** = 4, output with **inRange** = 12*

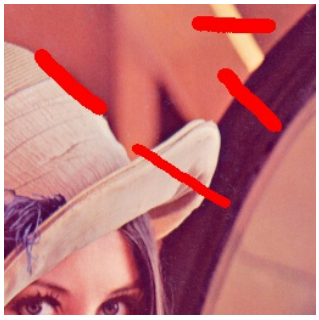


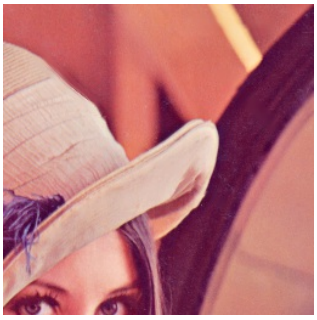
*Comparison between low and high values of **inPreSmoothing**. From the left: input, output with **inPreSmoothing** = 1, output with **inPreSmoothing** = 3*



*Comparison between low and high values of **inPostSmoothing**. From the left: input, output with **inPostSmoothing** = 1, output with **inPostSmoothing** = 6*

*Comparison between different values of **inSharpness**. From top left: input, output with **inSharpness** = 1, output with **inSharpness** = 25, output with **inSharpness** = 100*





*An example inpaint done with **inRange** = 6, **inPreSmoothing** = 1.5, **inPostSmoothing** = 6 and **inSharpness** = 35*

Errors

List of possible exceptions:

Error type	Description
DomainError	Expainting region (inRegionToExpaint) exceeds the image in InpaintImage_Bornemann.
DomainError	No pixels available at the edge of inRegionToExpaint in InpaintImage_Bornemann.

See Also

- InpaintImage_Telea – Fills in a region of an image with pixel values interpolated from the borders of the area; uses fast marching method.
- ExpaintImage_Telea – Speculatively sets pixel values outside of a region using the fast marching method.
- ExpaintImage_Bornemann – Speculatively sets pixel values outside of a region using the fast marching method and coherence analysis.

InpaintImage_Telea

Header: AVL.h
Namespace: avl
Module: FoundationPro

Fills in a region of an image with pixel values interpolated from the borders of the area; uses fast marching method.

Applications: Speculative setting of unknown (or unwanted) pixels. This version is trying to do this better than with simple interpolation.

Syntax

```
void avl::InpaintImage_Telea
(
 const avl::Image& inImage,
 const avl::Region& inRegionToInpaint,
 const int inRange,
 avl::Image& outImage
)
```

Parameters

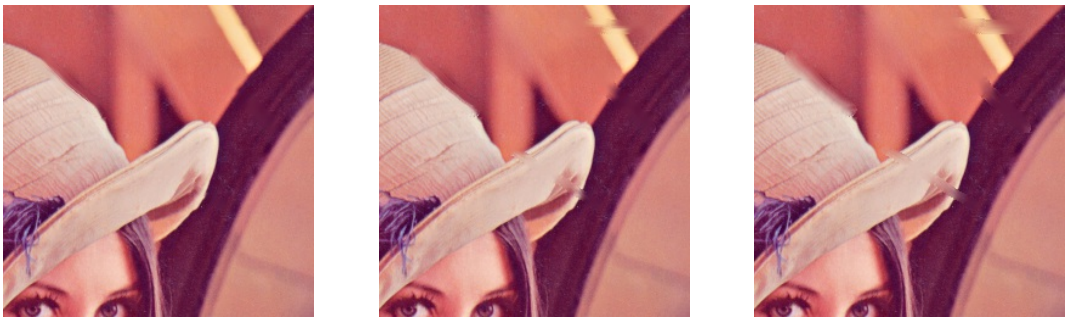
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRegionToInpaint	const Region&			
→	inRange	const int	1 – +∞	6	Defines how far a pixel can be from one currently being inpainted to be considered in calculations
←	outImage	Image&			Output image

Description

This filter inpaint a region of an image using the fast marching method. It is a simper version of InpaintImage_Bornemann in that it only uses the shape of the inpainting region and doesn't use structural information of the image.

Each inpainted pixel is filled with a color calculated as a weighted average of all already known (i.e. those outside of the inpainting range or those that were already) pixels withing a range specified by the parameter **inRange**. Using a higher range will result in smoother edges withing the inpainted region.

Examples



*Comparison between low and high values of **inRange**. From the left: input, output with **inRange** = 4, output with **inRange** = 12*

Errors

List of possible exceptions:

Error type	Description
DomainError	Expainting region (inRegionToExpaint) exceeds the image in InpaintImage_Telea.
DomainError	No pixels available at the edge of inRegionToInpaint in InpaintImage_Telea.

See Also

- InpaintImage – Fills in a region of an image with pixel values interpolated from the borders of the area.
- InpaintImage_Bornemann – Fills in a region of an image with pixel values interpolated from the borders of the area; uses fast marching method and coherence analysis.
- ExpaintImage_Telea – Speculatively sets pixel values outside of a region using the fast marching method.
- ExpaintImage_Bornemann – Speculatively sets pixel values outside of a region using the fast marching method and coherence analysis.

Also in AVL Lite

NormalizeImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.

Applications: Aims at better using the image's dynamic range to represent an interesting subset of pixel values.

Syntax

```
void avl::NormalizeImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inNewMinimum,
 float inNewMaximum,
 float inSaturateBrightestFraction,
 float inSaturateDarkestFraction,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 avl::Image& outImage,
 float& outA,
 float& outB,
 avl::Region& diagLinearNormalizedRegion
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
➡	inNewMinimum	float		0.0f	Desired minimum value of the resulting image
➡	inNewMaximum	float		255.0f	Desired maximum value of the resulting image
➡	inSaturateBrightestFraction	float	0.0 – 1.0	0.0f	Fraction of the brightest pixels skipped during normalization
➡	inSaturateDarkestFraction	float	0.0 – 1.0	0.0f	Fraction of the darkest pixels skipped during normalization
➡	inMinValue	Optional<float>		NIL	Pixels darker than that value will be skipped during normalization
➡	inMaxValue	Optional<float>		NIL	Pixels brighter than that value will be skipped during normalization
⬅	outImage	Image&			Rescaled image
⬅	outA	float&			Multiplicative parameter of the applied linear transformation of pixel values
⬅	outB	float&			Additive parameter of the applied linear transformation of pixel values
🔍	diagLinearNormalizedRegion	Region&			Region of image that has been linearly normalized

Description

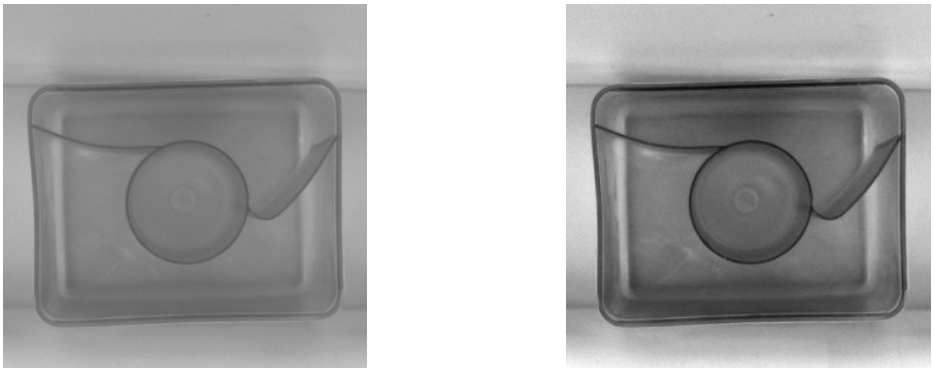
This filter linearly scales the pixel values of an image in order to make the histogram span the desired range of values.

The operation computes the parameters A, B of the linear transform that scales the image values to the desired range and applies the transform computing the results as follows:

$$\begin{aligned} outImage[i,j] &= inImage[i,j] \times A + B \\ outA &= A \\ outB &= B \end{aligned}$$

The **inSaturateBrightestFraction** and **inSaturateDarkestFraction** parameters can be used to make image normalization independent from salt and pepper noise. The normalization skips a chosen fraction of the brightest and the darkest pixels during counting A and B. The brightest and darkest pixels are set to **inNewMaximum** and **inNewMinimum** respectively, while the rest of the image is linearly scaled. A region of the linear scaling is available on **diagLinearNormalizedRegion** diagnostic output. For example, setting **inSaturateBrightestFraction** to 0.01 causes skipping 1 percent of the brightest pixels during counting A and B. Please note that the **inSaturateBrightestFraction** and **inSaturateDarkestFraction** parameters can be non-zero only for images with UInt8, Int8, UInt16 or Int16 pixel type.

Examples



NormalizeImage *run on example image.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty image on input in NormalizeImage.
DomainError	Region exceeds an input image in NormalizeImage.
DomainError	The inSaturationFraction inputs cannot be used for images with this pixel type in NormalizeImage.
DomainError	The sum of inSaturateBrightestFraction and inSaturateDarkestFraction can't be greater than 1 in NormalizeImage.

See Also

- RescalePixels – Applies linear transformation to pixel values.
- ResaturateImage – Sets pixels below the low value to minimum, above the high value to maximum, and interpolates the rest.
- AddToImage – Adds a scalar value to each pixel.

NormalizeLocalBrightness_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Normalizes local brightness of the image. Internally uses Gauss smoothing.

Applications: Compensates uneven illumination.

Syntax

```
void avl::NormalizeLocalBrightness_Gauss
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inTargetMean,
 float inGammaValue,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inStdDevX	float	0.0 – ∞	5.0f	Horizontal smoothing standard deviation
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Vertical smoothing standard deviation
→	inTargetMean	float		128.0f	Target mean brightness
→	inGammaValue	float	0.01 – 8.0	1.0f	Gamma coefficient, where 1.0 is neutral
←	outImage	Image&			Output image

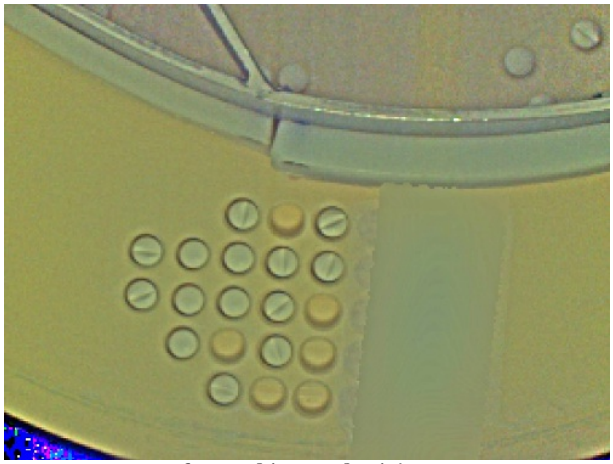
Description

This filter normalizes every pixels brightness to **inTargetMean** based on a local average calculated using **SmoothImage_Gauss** passing to it parameters **inStdDevX** and **inStdDevY**.

Gamma correction can be performed on the image before normalization through the **inGammaValue** parameter.

Examples

Example image



Output of NormalizeLocalBrightness_Gauss

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- NormalizeImage – Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.
- NormalizeLocalContrast – Normalizes local contrast of the image using Wallis filter.
- NormalizeLocalBrightness_Mean – Normalizes local brightness of the image. Internally uses Mean smoothing.
- SmoothImage_Gauss – Smooths an image using a gaussian kernel.

NormalizeLocalBrightness_Mean

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Normalizes local brightness of the image. Internally uses Mean smoothing.

Applications: Compensates uneven illumination.

Syntax

```
void avl::NormalizeLocalBrightness_Mean
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 float inTargetMean,
 float inGammaValue,
 avl::Image& outImage
)
```

Parameters

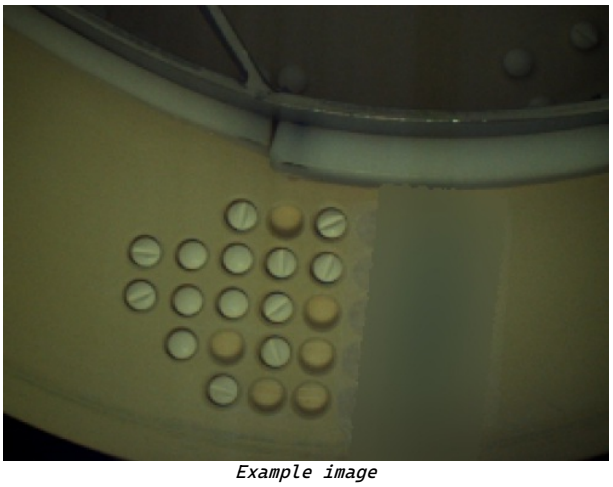
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inRadiusX	int	0 – ∞	10	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
→	inTargetMean	float		128.0f	Target mean brightness
→	inGammaValue	float	0.01 – 8.0	1.0f	Gamma coefficient, where 1.0 is neutral
←	outImage	Image&			Output image

Description

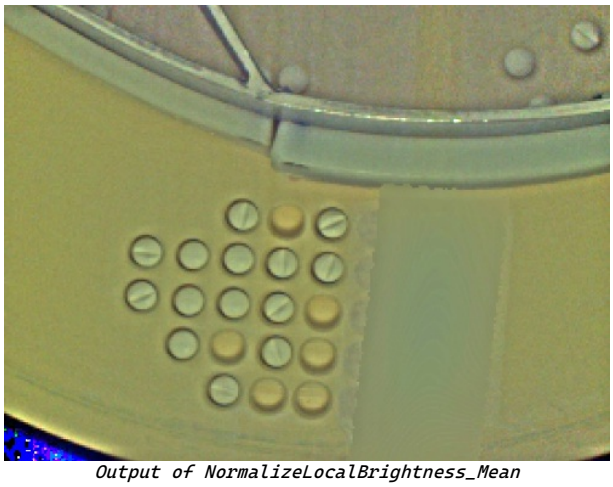
This filter normalizes every pixels brightness to **inTargetMean** based on a local average calculated using **SmoothImage_Mean** passing to it parameters **inRadiusX** and **inRadiusY**.

Gamma correction can be performed on the image before normalization through the **inGammaValue** parameter.

Examples



Example image



Output of NormalizeLocalBrightness_Mean

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- NormalizeImage – Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.
- NormalizeLocalContrast – Normalizes local contrast of the image using Wallis filter.
- NormalizeLocalBrightness_Gauss – Normalizes local brightness of the image. Internally uses Gauss smoothing.
- SmoothImage_Mean – Smooths an image by averaging pixels within a rectangular kernel.

NormalizeLocalContrast

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Normalizes local contrast of the image using Wallis filter.

Syntax

```
void avl::NormalizeLocalContrast
(
 const avl::Image& inMonoImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inTargetMean,
 const float inTargetVariance,
 const int inUniformnessScale,
 const float inBrightnessPreserveRatio,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMonoImage	const Image&			Monochromatic input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inTargetMean	const float		128.0f	Target local mean
→	inTargetVariance	const float	0.1 – ∞	90.0f	Target local variance
→	inUniformnessScale	const int	1 – + ∞	10	Radius of neighbourhood to uniformize
→	inBrightnessPreserveRatio	const float	0.0 – 1.0	0.1f	How much of original brightness to be kept
←	outImage	Image&			Output image

Requirements

For input **inMonoImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Description

This filter resaturates every pixel of monochromatic image **inMonoImage** so that its neighbourhood matches approximately average of **inTargetMean** and variance of **inTargetVariance** using Wallis algorithm.

Parameter **inUniformnessScale** determines the radius of the neighbourhood.

Parameter **inBrightnessPreserveRatio** determines how much of the original brightness is kept on the resulting image.

New value of pixel is given by:

$$P_{new} = A\,P_{old} + B$$

where

$$A = \frac{Var_{new}}{\frac{90}{CFC} + Var_{loc}}$$

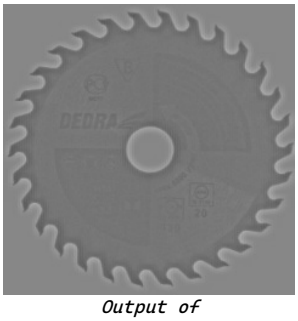
$$B = Mean_{new}(1 - BPR) + Mean_{loc}(BPR - A)$$

and

- Dev_{loc} and $Mean_{loc}$ are local deviation and mean respectively, taken from the square neighbourhood of radius **inUniformnessScale**
- Dev_{new} and $Mean_{new}$ are target deviation and mean respectively, **inTargetVariance** and **inTargetMean**
- CFC is Contrast Force Constant, set to 0.9
- BPR is **inBrightnessPreserveRatio**

Examples

Example image



Output of NormalizeLocalContrast filter

Previous image with NormalizeImage filter applied to it

Remarks

After the filter is run on the image, the neighbourhoods of pixels **do not** have desired variance and average. First reason for that is presence of constants BPR and CFC. Second reason is that forcing matching given average would require solving system of as many linear equations as there are pixels on the image.

Errors

List of possible exceptions:

Error type	Description
DomainError	Mono image expected on input in NormalizeLocalContrast.
DomainError	Region exceeds an input image in NormalizeLocalContrast.
DomainError	Not supported inMonoImage pixel format in NormalizeLocalContrast. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

See Also

- RescalePixels – Applies linear transformation to pixel values.
- ResaturateImage – Sets pixels below the low value to minimum, above the high value to maximum, and interpolates the rest.
- AddToImage – Adds a scalar value to each pixel.
- NormalizeImage – Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.

SharpenImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enhances contrast of an image so that it appears sharper.

Applications: Use this filter only to improve human perception, not to preprocess an image for analysis.

Syntax

```
void avl::SharpenImage
(
 const avl::Image& inImage,
 float inContrastFactor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

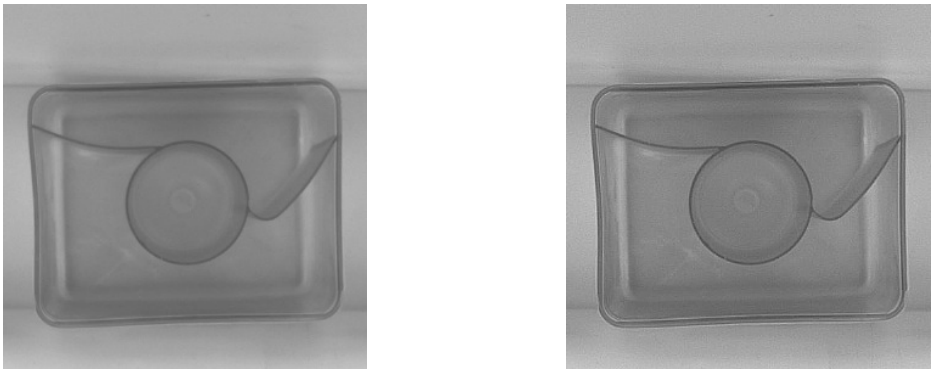
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inContrastFactor	float	0.0 – ∞	1.0f	Value representing the strength of the contrast enhancement
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Description

This filter increases the contrast of the image by multiplying by **inContrastFactor** the difference between a pixel value and its corresponding pixel value in the smoothed input image:

$$outImage[i,j] = inImage[i,j] + inContrastFactor \times (inImage[i,j] - smoothedImage[i,j])$$

Examples



SharpenImage *run on example image with* ***inContrastFactor*** *= 2.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE41 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Table of content:

- AverageAngle
- AveragePoint
- LerpAngles
- LerpPaths
- LerpPoints
- LerpSegments
- LerpVectors
- LerpVectors_Radial
- MedianAngle

AverageAngle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of the input angles using points on a unit circle.

Syntax

```
void avl::AverageAngle
(
 const atl::Array<float>& inAngles,
 avl::AngleRange::Type inAngleRange,
 float& outAverageAngle
)
```

Parameters

	Name	Type	Default	Description
→	inAngles	const Array<float>&		
→	inAngleRange	AngleRange::Type	_0_180	
←	outAverageAngle	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in AverageAngle.

Also in AVL Lite

AveragePoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the middle point of two input points.

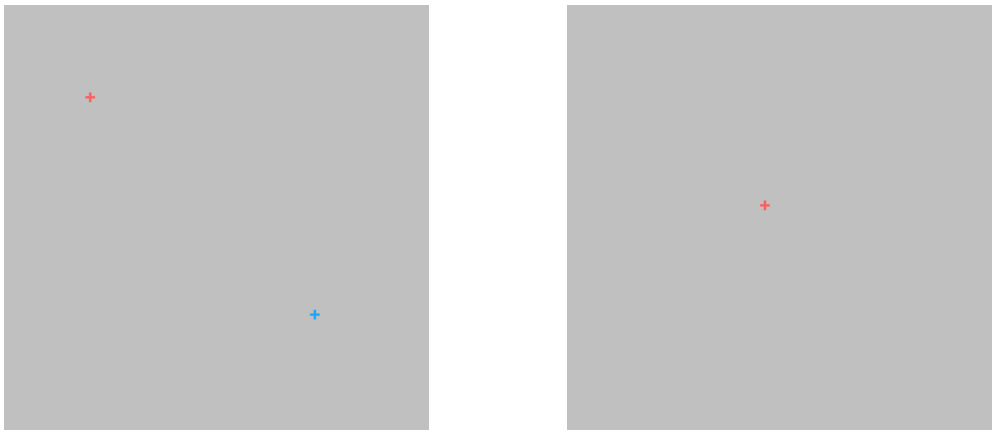
Syntax

```
void avl::AveragePoint
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		
→	inPoint2	const Point2D&		
←	outPoint	Point2D&		

Examples



AveragePoint *performed on two points.*

Also in AVL Lite

LerpAngles

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two angles in the direction of minimum turn.

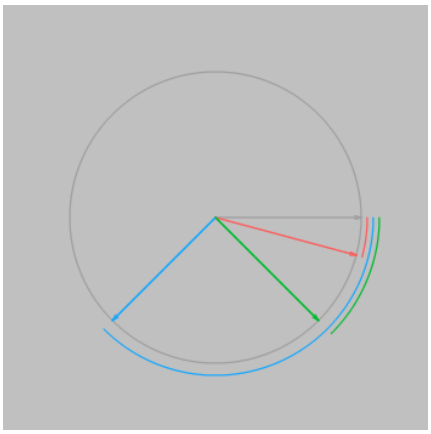
Syntax

```
void avl::LerpAngles
(
 float inAngle0,
 float inAngle1,
 atl::Optional<avl::RotationDirection::Type> inRotationDirection,
 avl::AngleRange::Type inAngleRange,
 float inLambda,
 bool inInverse,
 float& outAngle
)
```

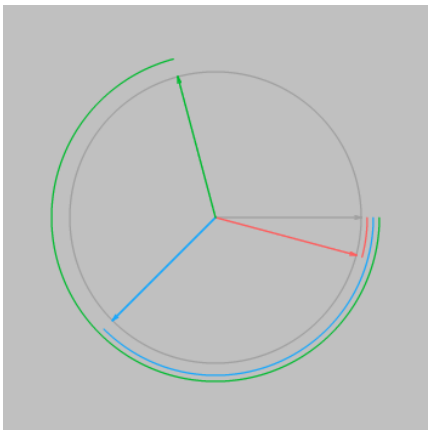
Parameters

	Name	Type	Default	Description
→	inAngle0	float		
→	inAngle1	float		
→	inRotationDirection	Optional<RotationDirection::Type>	NIL	Clockwise, counter-clockwise or auto
→	inAngleRange	AngleRange::Type	_0_180	
→	inLambda	float		Interpolation between the input angles where 0.0 value is equal to inAngle0 and 1.0 to inAngle1
→	inInverse	bool		
←	outAngle	float&		

Examples



LerpAngles *performed on red* ***inAngle0*** *= 15 and blue* ***inAngle1*** *= 135 with* ***inLambda*** *= 0,25 and* ***inAngleRange*** *= 0-360. Green is the resulting* ***outAngle****.*



LerpAngles *performed on red* ***inAngle0*** *= 15 and blue* ***inAngle1*** *= 135 with* ***inLambda*** *= -1,0 and* ***inAngleRange*** *= 0-360. Green is the resulting* ***outAngle****.*

Remarks

Please note that:

- interpolation begins at **inAngle0**,
- for positive **inLambda** values interpolation is performed in the direction given in the **inRotationDirection** parameter while for negative - in the inverted direction.

Hence when **inLambda** = 0,0, **outAngle** is equal to **inAngle0**, while for **inLambda** = 1,0 it's the same as **inAngle1** and for **inLambda** = -1,0 - as (**inAngle0** - **inAngle1**). Other **inLambda** values interpolate between the input angles and beyond.

LerpPaths

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two paths.

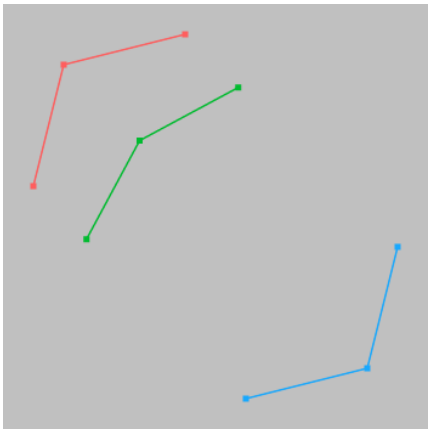
Syntax

```
void avl::LerpPaths
(
 const avl::Path& inPath0,
 const avl::Path& inPath1,
 const float inLambda,
 avl::Path& outPath
)
```

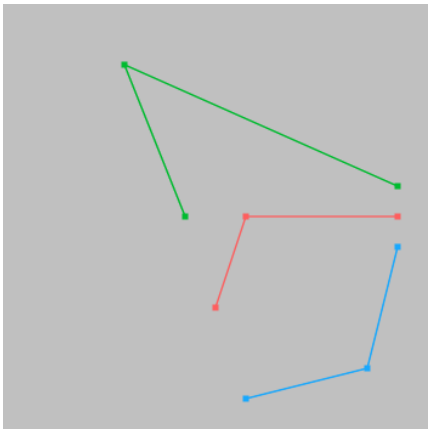
Parameters

	Name	Type	Range	Default	Description
→	inPath0	const Path&			
→	inPath1	const Path&			First input path
→	inLambda	const float	$-\infty$ – ∞	0.5f	Interpolation between the input paths where 0.0 value is equal to inPath0 and 1.0 to inPath1
←	outPath	Path&			Output path

Examples



LerpPaths *performed on red* ***inPath0*** *and blue* ***inPath1*** *with* ***inLambda*** *= 0,25. Green is the resulting* ***outPath****.*



LerpPaths *performed on red* ***inPath0*** *and blue* ***inPath1*** *with* ***inLambda*** *= -1,0. Green is the resulting* ***outPath****.*

Remarks

Please note that:

- interpolation begins at **inPath0**,
- for positive **inLambda** values interpolation is performed in the direction of **inPath1** while for negative – in the direction of a path which is the result of the following operation: (**inPath0** – **inPath1**), in example a path consisting of **inPath1** points mirrored by the corresponding **inPath0** points.

Hence when **inLambda** = 0,0, **outPath** is equal to **inPath0**, while for **inLambda** = 1,0 it's the same as **inPath1** and for **inLambda** = -1,0 – as (**inPath0** – **inPath1**). Other **inLambda** values interpolate between the input paths and beyond.

Errors

List of possible exceptions:

Error type	Description
DomainError	Numbers of points in paths are not the same in LerpPaths.
DomainError	Open and closed paths on input in LerpPaths.

Also in **AVL Lite**

LerpPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two points.

Syntax

```
void avl::LerpPoints
(
 const avl::Point2D& inPoint0,
 const avl::Point2D& inPoint1,
 float inLambda,
 avl::Point2D& outPoint
)
```

Parameters

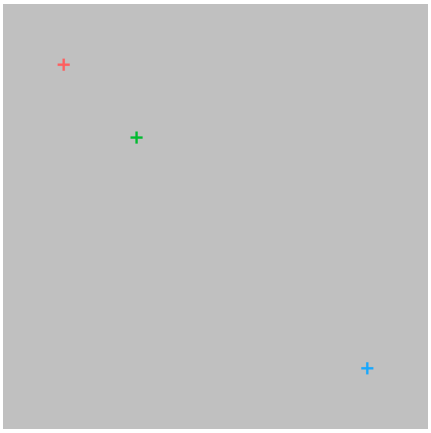
	Name	Type	Range	Default	Description
→	inPoint0	const Point2D&			
→	inPoint1	const Point2D&			
→	inLambda	float	$-\infty$ – ∞	0.5f	Interpolation between the input points where 0.0 value is equal to inPoint0 and 1.0 to inPoint1
←	outPoint	Point2D&			

In-place Processing

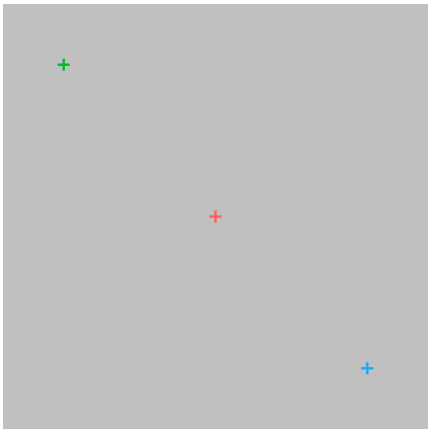
This function supports in-place data processing - you can pass the same reference to **inPoint1** and **outPoint**

Read more about In-place Computation.

Examples



***LerpPoints** performed on red **inPoint0** and blue **inPoint1** with **inLambda** = 0,25. Green is the resulting **outPoint**.*



***LerpPoints** performed on red **inPoint0** and blue **inPoint1** with **inLambda** = -1,0. Green is the resulting **outPoint**.*

Remarks

Please note that:

- interpolation begins at **inPoint0**,
- for positive **inLambda** values interpolation is performed in the direction of **inPoint1** while for negative - in the direction of a point which is the result of the following operation: (**inPoint0** - **inPoint1**), in example a point acquired by mirroring **inPoint1** by **inPoint0**.

Hence when **inLambda** = 0,0, **outPoint** is equal to **inPoint0**, while for **inLambda** = 1,0 it's the same as **inPoint1** and for **inLambda** = -1,0 - as (**inPoint0** - **inPoint1**). Other **inLambda** values interpolate between the input points and beyond.

Also in **AVL Lite**

LerpSegments

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two segments.

Syntax

```
void avl::LerpSegments
(
 const avl::Segment2D& inSegment0,
 const avl::Segment2D& inSegment1,
 float inLambda,
 bool inIgnoreOrientation,
 avl::Segment2D& outSegment
)
```

Parameters

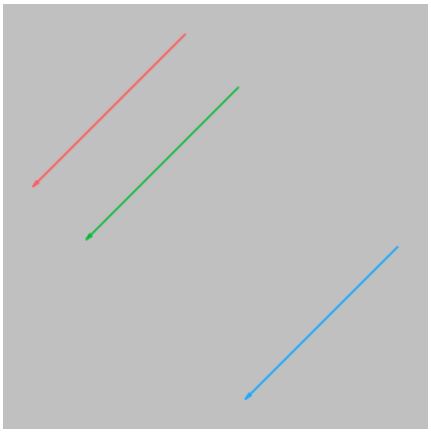
	Name	Type	Range	Default	Description
→	inSegment0	const Segment2D&			
→	inSegment1	const Segment2D&			
→	inLambda	float	-∞ - ∞	0.5f	Interpolation between the input segments where 0.0 value is equal to inSegment0 and 1.0 to inSegment1
→	inIgnoreOrientation	bool			
←	outSegment	Segment2D&			

In-place Processing

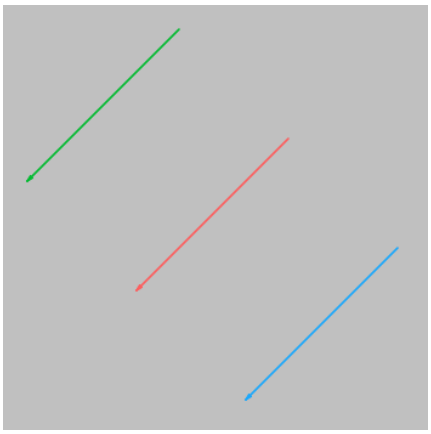
This function supports in-place data processing - you can pass the same reference to **inSegment1** and **outSegment**

Read more about In-place Computation.

Examples



LerpSegments *performed on red* ***inSegment0*** *and blue* ***inSegment1*** *with* ***inLambda*** *= 0,25. Green is the resulting* ***outSegment****.*



LerpSegments *performed on red* ***inSegment0*** *and blue* ***inSegment1*** *with* ***inLambda*** *= -1,0. Green is the resulting* ***outSegment****.*

Remarks

Please note that:

- interpolation begins at **inSegment0**,
- for positive **inLambda** values interpolation is performed in the direction of **inSegment1** while for negative - in the direction of a segment which is the result of the following operation: (**inSegment0** - **inSegment1**), in example a segment consisting of **inSegment1** points mirrored by the corresponding **inSegment0** points.

Hence when **inLambda** = 0,0, **outSegment** is equal to **inSegment0**, while for **inLambda** = 1,0 it's the same as **inSegment1** and for **inLambda** = -1,0 - as (**inSegment0** - **inSegment1**). Other **inLambda** values interpolate between the input segments and beyond.

LerpVectors

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two vectors.

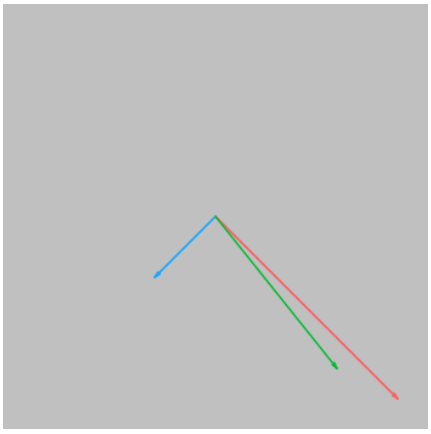
Syntax

```
void avl::LerpVectors
(
 const avl::Vector2D& inVector0,
 const avl::Vector2D& inVector1,
 const float inLambda,
 avl::Vector2D& outVector
)
```

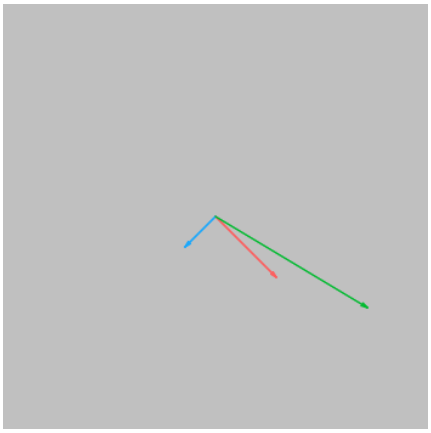
Parameters

	Name	Type	Range	Default	Description
→	inVector0	const Vector2D&			
→	inVector1	const Vector2D&			
→	inLambda	const float	-∞ – ∞	0.5f	Interpolation between the input vectors where 0.0 value is equal to inVector0 and 1.0 to inVector1
←	outVector	Vector2D&			

Examples



LerpVectors *performed on red* ***inVector0*** *= (150, 150) and blue* ***inVector1*** *= (-50, 50) with* ***inLambda*** *= 0,25. Green is the resulting* ***outVector****.*



LerpVectors *performed on red* ***inVector0*** *= (50, 50) and blue* ***inVector1*** *= (-25, 25) with* ***inLambda*** *= -1,0. Green is the resulting* ***outVector****.*

Remarks

Please note that:

- interpolation begins at **inVector0**,
- for positive **inLambda** values interpolation is performed in the direction of **inVector1** while for negative – in the direction of a vector which, when visualized with the same base point, ends in the point acquired by mirroring the head of **inVector0** by a line perpendicular to the vector (**inVector0** – **inVector1**).

Hence when **inLambda** = 0,0, **outVector** is equal to **inVector0**, while for **inLambda** = 1,0 it's the same as **inVector1** and for **inLambda** = −1,0 – as the previously described vector. Other **inLambda** values interpolate between the input vectors and beyond.

Also in AVL Lite

LerpVectors_Radial

Header: AVL.h
Namespace: avl
Module: FoundationLite

Linearly interpolates between two radial vectors.

Syntax

```
void avl::LerpVectors_Radial
(
 const avl::Vector2D& inVector0,
 const avl::Vector2D& inVector1,
 atl::Optional<avl::RotationDirection::Type> inRotationDirection,
 const float inLambda,
 avl::Vector2D& outVector
)
```

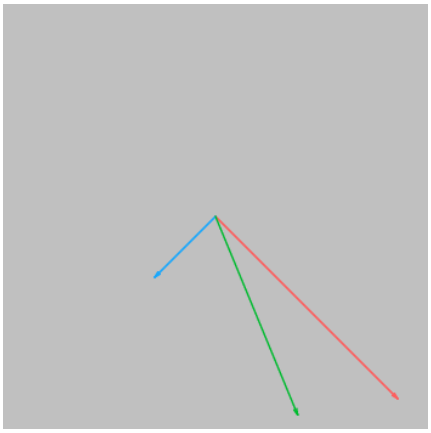
Parameters

	Name	Type	Range	Default	Description
→	inVector0	const Vector2D&			
→	inVector1	const Vector2D&			
→	inRotationDirection	Optional<RotationDirection::Type>		NIL	Clockwise, counter-clockwise or auto
→	inLambda	const float	-∞ -∞	0.5f	Interpolation between the input vectors where 0.0 value is equal to inVector0 and 1.0 to inVector1
←	outVector	Vector2D&			

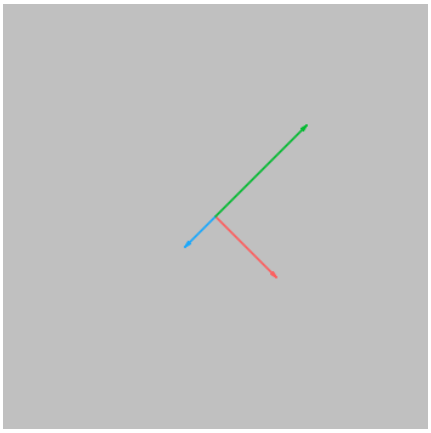
Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when a zero vector is given on input.

Examples



***LerpVectors** performed on red **inVector0** = (150, 150) and blue **inVector1** = (-50, 50) with **inLambda** = 0,25 and **inRotationDirection** = Clockwise. Green is the resulting **outVector**.*



***LerpVectors** performed on red **inVector0** = (50, 50) and blue **inVector1** = (-25, 25) with **inLambda** = -1,0 and **inRotationDirection** = Clockwise. Green is the resulting **outVector**.*

Remarks

Please note that:

- interpolation begins at **inVector0**,
- for positive **inLambda** values interpolation is performed in the direction of **inVector1** while for negative – in the direction of a vector acquired by mirroring **inVector1** by a line determined by **inVector0** and its length properly adjusted.

Hence when **inLambda** = 0,0, **outVector** is equal to **inVector0**, while for **inLambda** = 1,0 it's the same as **inVector1** and for **inLambda** = -1,0 – as the previously described vector. Other **inLambda** values interpolate between the input vectors and beyond.

MedianAngle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the median angle of the input angles.

Applications: This is a substitute for arithmetic average which cannot be done well for angles. For example the average of 1 and 359 is incorrectly 180 (we think 0).

Syntax

```
void avl::MedianAngle
(
 const atl::Array<float>& inAngles,
 avl::AngleRange::Type inAngleRange,
 float& outMedianAngle
)
```

Parameters

	Name	Type	Default	Description
→	inAngles	const Array<float>&		
→	inAngleRange	AngleRange::Type	_0_180	
←	outMedianAngle	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in MedianAngle.

AveragePath

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of two paths (of equal size and type) point by point.

Syntax

```
void avl::AveragePath
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath1	const Path&		Input path
→	inPath2	const Path&		Input path
←	outPath	Path&		Output path

In-place Processing

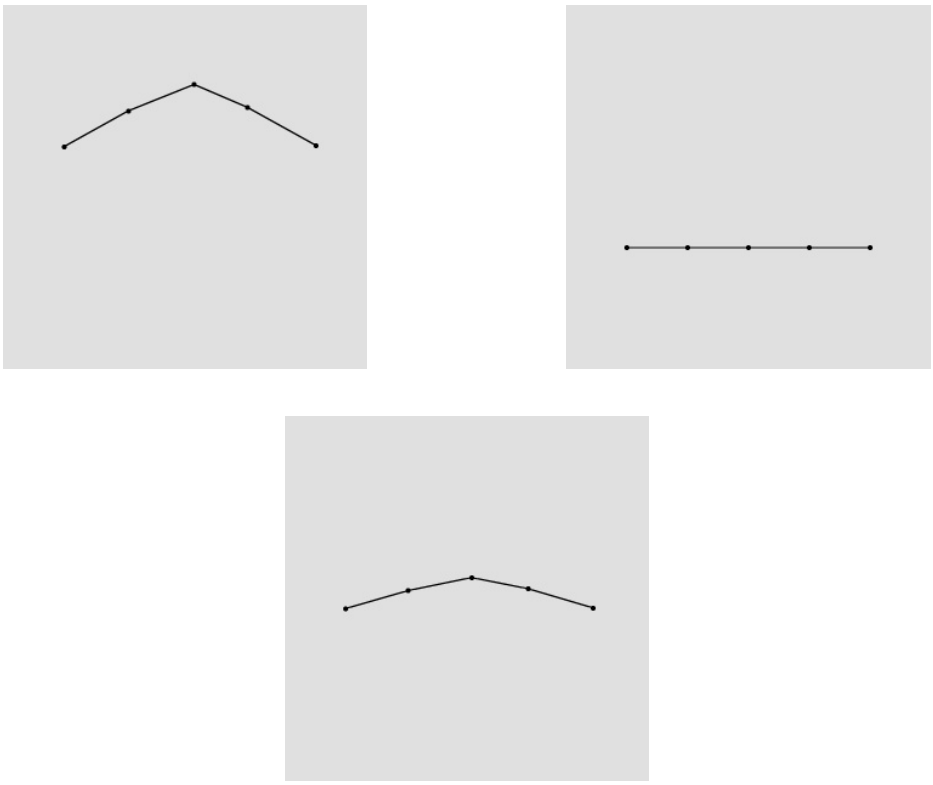
This function supports in-place data processing - you can pass the same reference to **inPath1** and **outPath**, **inPath2** and **outPath**

Read more about In-place Computation.

Description

The operation computes the average of two paths of equal **size** and **type** (open/closed). Each point of the resulting path is an average of the corresponding points in the input paths.

Examples



AveragePath *run on the sample paths.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input paths have unequal size in AveragePath.
DomainError	Open/closed paths mismatch in AveragePath.

ConcatenatePaths

Header: AVL.h
Namespace: avl
Module: FoundationLite

Joins up to four open paths.

Syntax

```
void avl::ConcatenatePaths
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 const avl::Path& inPath3,
 const avl::Path& inPath4,
 bool inClose,
 avl::Path& outPath
)
```

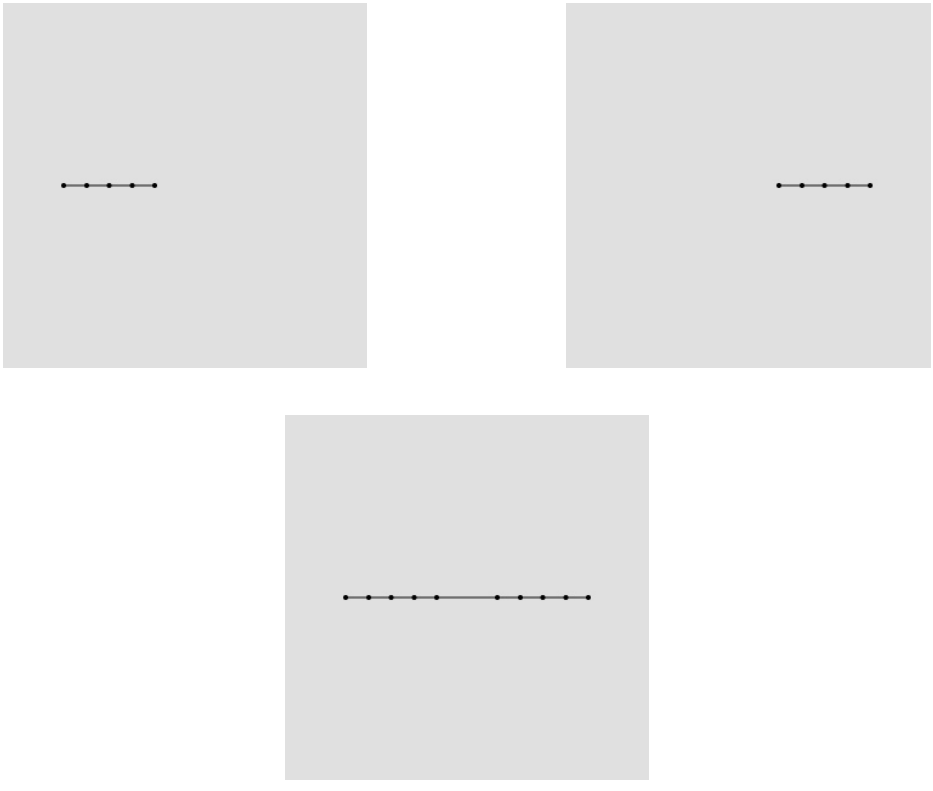
Parameters

	Name	Type	Default	Description
→	inPath1	const Path&		Input path
→	inPath2	const Path&		Input path
→	inPath3	const Path&		Input path
→	inPath4	const Path&		Input path
→	inClose	bool		If set to true adding in result a segment between its first point and the last one, therefore producing a closed path
←	outPath	Path&		Output path

Description

The operations joins two open paths adding a segment connecting the end of the **inPath1** to the begin of **inPath2**.

Examples



ConcatenatePaths *run on the sample paths.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Closed path on input in ConcatenatePaths.

Also in AVL Lite

ConcatenatePaths_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Joins open paths of an array.

Syntax

```
void avl::ConcatenatePaths_OfArray
(
 const atl::Array<avl::Path>& inPathArray,
 bool inClose,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPathArray	const Array<Path>&		Input paths
→	inClose	bool		If set to true adding in result a segment between its first point and the last one, therefore producing a closed path
←	outPath	Path&		Output path

Description

Array version of ConcatenatePaths.

Errors

List of possible exceptions:

Error type	Description
DomainError	Closed path on input in ConcatenatePaths_OfArray.

See Also

- ConcatenatePaths – Joins up to four open paths.

ConcatenatePaths_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Joins open paths appearing in consecutive iterations.

Syntax

```
void avl::ConcatenatePaths_OfLoop
(
 ConcatenatePaths_OfLoopState& ioState,
 const avl::Path& inPath,
 bool inClose,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
	ioState	ConcatenatePaths_OfLoopState&		Object used to maintain state of the function.
	inPath	const Path&		Input path
	inClose	bool		If set to true adding in result a segment between its first point and the last one, therefore producing a closed path
	outPath	Path&		Output path

Description

Loop version of ConcatenatePaths.

Errors

List of possible exceptions:

Error type	Description
DomainError	Closed path on input in ConcatenatePaths_OfLoop.

See Also

- ConcatenatePaths – Joins up to four open paths.

JoinAdjacentPaths

Header: AVL.h
Namespace: avl
Module: FoundationPro

Joins those paths of an array which endpoints lie near enough.

Syntax

```
void avl::JoinAdjacentPaths
(
 const atl::Array<avl::Path>& inPaths,
 float inMaxDistance,
 float inMaxAngle,
 atl::Optional<float> inMaxDeviation,
 float inExcessTrim,
 atl::Optional<float> inEndingLength,
 avl::PathJoiningMethod::Type inJoiningMethod,
 avl::PathJoiningAngleMeasure::Type inAngleMeasure,
 bool inIgnorePathEndsOrder,
 bool inAllowCycles,
 float inMinPathLength,
 atl::Array<avl::Path>& outPaths,
 atl::Optional<atl::Array<avl::Path>&> outMatchedPieces = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPaths	const Array<Path>&			
→	inMaxDistance	float	0.0 – ∞	10.0f	Maximal distance between paths that can be joined
→	inMaxAngle	float	0.0 – 180.0	30.0f	Maximal allowed angle between paths being joined
→	inMaxDeviation	Optional<float>	0.0 – ∞	NIL	Maximal allowed thickness of a minimal stripe containing both paths being joined
→	inExcessTrim	float	0.0 – ∞		Length of the part of each path to be removed from its both sides
→	inEndingLength	Optional<float>	0.0 – ∞	0.0f	Determines the length of the path end used for path angle computing
→	inJoiningMethod	PathJoiningMethod::Type		AddBridge	Determines a method to join two paths in one
→	inAngleMeasure	PathJoiningAngleMeasure::Type		InputPathOrientation	Determines a method to measure the angle between two input paths
→	inIgnorePathEndsOrder	bool		True	If set to false, only the end of a path can be joined with the begin of another path
→	inAllowCycles	bool		True	Determines if cycles can be created during joining process
→	inMinPathLength	float	0.0 – ∞	0.0f	Minimal length of a path
←	outPaths	Array<Path>&			
←	outMatchedPieces	Optional<Array<Path>&>		NIL	Input paths that have been joined with another path

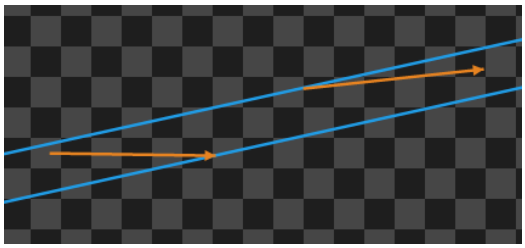
Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMatchedPieces**.

Read more about Optional Outputs.

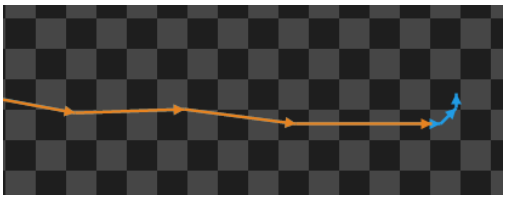
Description

The operation repeatedly connects the pair of endpoints of open paths of an array until no such pair can be connected. If an endpoint can be joined with more than one another, the endpoint which generates smallest joining value is chosen. The joining value is computed by combining distance between endpoints being joined, their angle difference and their deviation value. An endpoint can be joined with another one in its vicinity only if the distance between them is not greater than **inMaxDistance**. Their angle difference, which is computed in one of available ways depending on **inAngleMeasure** value, cannot be greater than **inMaxAngle**. Their deviation value, which is the thickness of a minimal stripe containing both path endings being joined, cannot exceed **inMaxDeviation**.



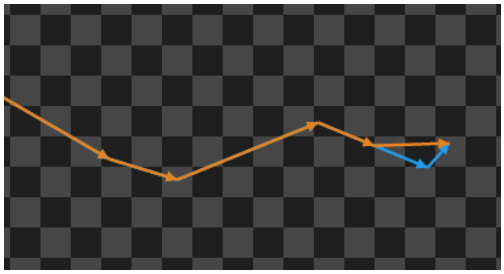
The deviation value for two orange segments is the distance between two parallel blue lines.

Before joining process begins, the input paths are shortened by **inExcessTrim** on both their ends. The parameter makes it possible to use the filter for paths that can be a bit curly on their ends.



*Only orange part of the path takes part in joining process. The curly blue path ending is removed by **inExcessTrim** parameter.*

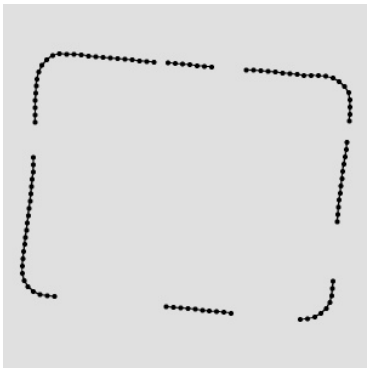
While joining takes place, the **inEndingLength** parameter determines what part of the path ending is used to determine the angle between two paths. If it is set to Nil, the segment connecting path begin and path end is decisive.

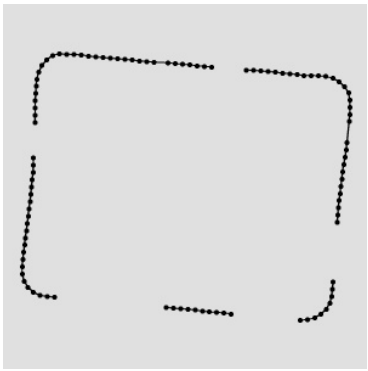


*The last orange segment is taken into account while determining angle between two paths. The omitted blue path ending has length **inEndingLength**.*

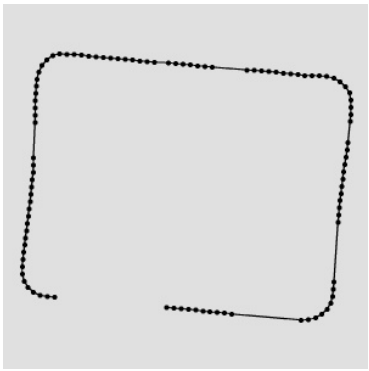
There are also two flags controlling the joining process. If the **inIgnorePathEndsOrder** is set, a path begin can also be joined with another path begin and a path end with another path end. Otherwise a path begin can be joined with a path end only. The **inAllowCycles** parameter determines if a cycle is allowed to emerge during joining. Finally, after the joining phase paths that are shorter than **inMinPathLength** are removed from the final results.

Examples





JoinAdjacentPaths *run on the sample path array with* ***inMaxDistance*** *= 25.*



JoinAdjacentPaths *run on the sample path array with* ***inMaxDistance*** *= 1000.*

See Also

- ClosePath – Adds the segment connecting the last point with the first one in a path.

PathLineIntersections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the common points of a path and a line.

Syntax

```
void avl::PathLineIntersections
(
 const avl::Path& inPath,
 const avl::Line2D& inLine,
 atl::Array<avl::Point2D>& outIntersectionPoints,
 atl::Optional<atl::Array<int>&> outSegmentIndices = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inLine	const Line2D&		Input line
←	outIntersectionPoints	Array<Point2D>&		Intersections between the path and the line
←	outSegmentIndices	Optional<Array<int>&>	NIL	Indices of the segments of the path which generate found intersection points

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSegmentIndices**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in PathLineIntersections.

PathPathIntersections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the common points of two paths.

Syntax

```
void avl::PathPathIntersections
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 atl::Array<avl::Point2D>& outIntersectionPoints,
 atl::Optional<atl::Array<int>&> outSegmentIndices1 = atl::NIL,
 atl::Optional<atl::Array<int>&> outSegmentIndices2 = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath1	const Path&		Input path
→	inPath2	const Path&		Input path
←	outIntersectionPoints	Array<Point2D>&		Intersections between the input paths
←	outSegmentIndices1	Optional<Array<int>&>	NIL	Indices of the segments of the first path which generate found intersection points
←	outSegmentIndices2	Optional<Array<int>&>	NIL	Indices of the segments of the second path which generate found intersection points

Optional Outputs

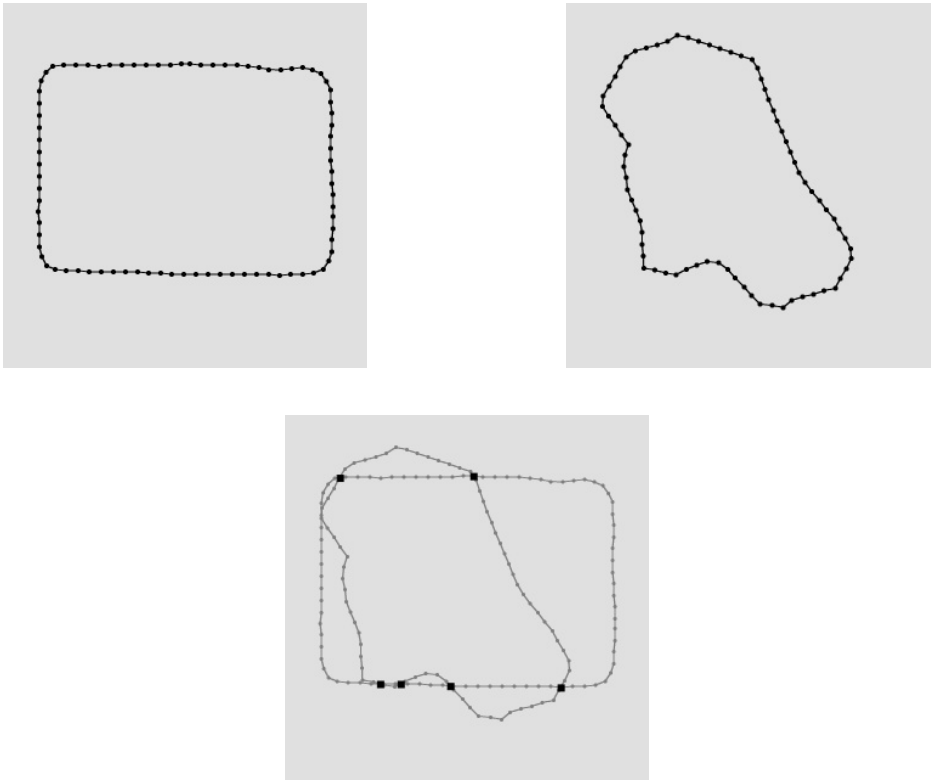
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSegmentIndices1**, **outSegmentIndices2**.

Read more about Optional Outputs.

Description

The operation computes an array of the intersection points of two given paths.

Examples



PathPathIntersections *run on the sample paths. The resulting* ***outIntersectionPoints*** *were drawn onto the input paths.*

PathSegmentIntersections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the common points of a path and a segment.

Syntax

```
void avl::PathSegmentIntersections
(
 const avl::Path& inPath,
 const avl::Segment2D& inSegment,
 atl::Array<avl::Point2D>& outIntersectionPoints,
 atl::Optional<atl::Array<int>&> outSegmentIndices = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inSegment	const Segment2D&		Input segment
←	outIntersectionPoints	Array<Point2D>&		Intersections between the path and the segment
←	outSegmentIndices	Optional<Array<int>&>	NIL	Indices of the segments of the path which generate found intersection points

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSegmentIndices**.

Read more about Optional Outputs.

SplitPathByLine

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits path in common points of a path and a line.

Syntax

```
void avl::SplitPathByLine
(
 const avl::Path& inPath,
 const avl::Line2D& inLine,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Path being split
→	inLine	const Line2D&		Line used for splitting
←	outPaths	Array<Path>&		Paths arisen from splitting the initial path

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in SplitPathByLine.

SplitPathByPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Splits path in common points of two paths.

Syntax

```
void avl::SplitPathByPath
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPath1	const Path&		Path being split
→	inPath2	const Path&		Path used for splitting
←	outPaths	Array<Path>&		Paths arisen from splitting the initial path

SplitPathBySegment

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits path in common points of a path and a segment.

Syntax

```
void avl::SplitPathBySegment
(
 const avl::Path& inPath,
 const avl::Segment2D& inSegment,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Path being split
→	inSegment	const Segment2D&		Segment used for splitting
←	outPaths	Array<Path>&		Paths arisen from splitting the initial path

CreateArc

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an arc from an aligned point, radius, and angle range.

Syntax

```
void avl::CreateArc
(
 const avl::Point2D& inPoint,
 avl::Anchor2D::Type inPointAnchor,
 float inRadius,
 float inStartAngle,
 float inSweepAngle,
 avl::Arc2D& outArc
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inPointAnchor	Anchor2D::Type		MiddleCenter	Alignment of the point relatively to the box of the circle
→	inRadius	float	0.0 – ∞		Circle radius
→	inStartAngle	float			Direction at which the arc begins
→	inSweepAngle	float			Length of the arc (may be negative)
←	outArc	Arc2D&			

CreateCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a circle from an aligned point and radius.

Syntax

```
void avl::CreateCircle
(
 const avl::Point2D& inPoint,
 avl::Anchor2D::Type inPointAnchor,
 float inRadius,
 avl::Circle2D& outCircle
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inPointAnchor	Anchor2D::Type		MiddleCenter	Alignment of the point relatively to the box of the circle
→	inRadius	float	0.0 – ∞		Circle radius
←	outCircle	Circle2D&			

CreatePointGrid

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a grid of points.

Syntax

```
void avl::CreatePointGrid
(
 const avl::Point2D& inPoint,
 avl::Anchor2D::Type inAnchor,
 const int inRowCount,
 const int inColumnCount,
 const float inRowStep,
 const float inColumnStep,
 atl::Array<avl::Point2D>& outPointGrid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			A starting point of the created grid
→	inAnchor	Anchor2D::Type		TopLeft	Anchor of the reference point
→	inRowCount	const int	0 – +∞		Number of rows the grid will have
→	inColumnCount	const int	0 – +∞		Number of columns the grid will have
→	inRowStep	const float	0.0 – ∞	1.0f	Distance between consecutive rows of the created grid
→	inColumnStep	const float	0.0 – ∞	1.0f	Distance between consecutive columns of the created grid
←	outPointGrid	Array<Point2D>&			Created point grid

CreateRandomPointArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates array of random points inside given box.

Syntax

```
void avl::CreateRandomPointArray
(
 const int inLength,
 const avl::Box& inBox,
 const float inStep,
 atl::Optional<int> inSeed,
 atl::Array< avl::Point2D >& outArray
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLength	const int	0 – +∞	10	Length of output array
→	inBox	const Box&			Bounding box of generated point
→	inStep	const float	0.0001 – ∞	1.0f	Minimal difference between two generated values on each coordinate
→	inSeed	Optional<int>		NIL	Random seed
←	outArray	Array< Point2D >&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inStep is greater than height of box in CreateRandomPointArray.
DomainError	Value of inStep is greater than width of box in CreateRandomPointArray.

CreateRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a rectangle from an aligned point.

Syntax

```
void avl::CreateRectangle
(
 const avl::Point2D& inPoint,
 avl::Anchor2D::Type inPointAnchor,
 float inAngle,
 float inWidth,
 float inHeight,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inPointAnchor	Anchor2D::Type		TopLeft	Alignment of the input point relatively to the box of the position
→	inAngle	float			Clock-wise orientation angle
→	inWidth	float	0.0 – ∞		Width of the created rectangle
→	inHeight	float	0.0 – ∞		Height of the created rectangle
←	outRectangle	Rectangle2D&			

Also in AVL Lite

CreateRectangularPointGrid

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a grid of points in a described rectangle.

Syntax

```
void avl::CreateRectangularPointGrid
(
 const avl::Rectangle2D& inRectangle,
 const avl::CoordinateSystem2D& inAlignment,
 const int inRowCount,
 const int inColumnCount,
 const float inMarginWidth,
 const float inMarginHeight,
 atl::Array<avl::Point2D>& outPointGrid,
 avl::Rectangle2D& diagAlignedRectangle
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			Where points should be inscribed
→	inAlignment	const CoordinateSystem2D&			
→	inRowCount	const int	2 – +∞		Number of rows the grid will have
→	inColumnCount	const int	2 – +∞		Number of columns the grid will have
→	inMarginWidth	const float	0.0 – ∞		
→	inMarginHeight	const float	0.0 – ∞		
←	outPointGrid	Array<Point2D>&			Output points
🔍	diagAlignedRectangle	Rectangle2D&			

Also in AVL Lite

CreateRing

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a ring from an aligned point, inner and outer radius, and angle range.

Syntax

```
void avl::CreateRing
(
 const avl::Point2D& inPoint,
 avl::Anchor2D::Type inPointAnchor,
 float inInnerRadius,
 float inOuterRadius,
 avl::Ring2D& outRing
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inPointAnchor	Anchor2D::Type		MiddleCenter	Alignment of the point relatively to the box of the ring outer circle
→	inInnerRadius	float	0.0 – ∞		Inner ring radius
→	inOuterRadius	float	0.0 – ∞		Outer ring radius
←	outRing	Ring2D&			

CreateSegment

Header: AVL.h
Namespace: avl
Module: FoundationLite

Produces a segment of given parameters.

Syntax

```
void avl::CreateSegment
(
 const avl::Point2D& inPoint,
 float inPointAnchor,
 float inDirection,
 float inLength,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			A point on the created segment
→	inPointAnchor	float	0.0 – 1.0		Anchor point, 0 means the beginning, 1 means the end of the segment
→	inDirection	float			Desired direction of the segment in degrees
→	inLength	float			Desired length of the segment in pixels
←	outSegment	Segment2D&			The resulting segment

CreateVector

Header: AVL.h
Namespace: avl
Module: FoundationLite

Produces a vector of given length and direction.

Syntax

```
void avl::CreateVector
(
 float inLength,
 float inDirection,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Default	Description
→	inLength	float		Desired length of the vector in pixels
→	inDirection	float		Desired direction of the vector in degrees
←	outVector	Vector2D&		The resulting vector

RandomPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates random point inside given box.

Syntax

```
void avl::RandomPoint
(
 RandomState& ioState,
 const avl::Box& inBox,
 atl::Optional<int> inSeed,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RandomState&		Object used to maintain state of the function.
→	inBox	const Box&		Bounding box of generated point
→	inSeed	Optional<int>	NIL	Random seed
←	outPoint	Point2D&		

Also in AVL Lite

WKT_LoadLineString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads path from WKT text format.

Syntax

```
void avl::WKT_LoadLineString
(
 const atl::String& inText,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outPath	Path&		Output path

WKT_LoadMultiLineString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads multiple paths from WKT text format.

Syntax

```
void avl::WKT_LoadMultiLineString
(
 const atl::String& inText,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outPaths	Array<Path>&		

Also in AVL Lite

WKT_LoadMultiPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads multiple points from WKT text format.

Syntax

```
void avl::WKT_LoadMultiPoint
(
 const atl::String& inText,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outPoints	Array<Point2D>&		

WKT_LoadMultiPolygon

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads multiple polygons from WKT text format.

Syntax

```
void avl::WKT_LoadMultiPolygon
(
 const atl::String& inText,
 atl::Array<avl::Path>& outOuterPolygons,
 atl::Array<atl::Array<avl::Path>>& outInnerPolygons
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outOuterPolygons	Array<Path>&		
←	outInnerPolygons	Array<Array<Path>>&		

WKT_LoadMultiPolygon_AsRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads multiple polygons from WKT text format as region.

Syntax

```
void avl::WKT_LoadMultiPolygon_AsRegion
(
 const atl::String& inText,
 int inFrameWidth,
 int inFrameHeight,
 atl::Array<avl::Region>& outRegions
)
```

Parameters

	Name	Type	Range	Default	Description
→	inText	const String&			
→	inFrameWidth	int	0 – 65535		
→	inFrameHeight	int	0 – 65535		
←	outRegions	Array<Region>&			

WKT_LoadPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads point from WKT text format.

Syntax

```
void avl::WKT_LoadPoint
(
 const atl::String& inText,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outPoint	Point2D&		

Also in AVL Lite

WKT_LoadPolygon

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads polygon from WKT text format.

Syntax

```
void avl::WKT_LoadPolygon
(
 const atl::String& inText,
 avl::Path& outOuterPolygon,
 atl::Array<avl::Path>& outInnerPolygons
)
```

Parameters

	Name	Type	Default	Description
→	inText	const String&		
←	outOuterPolygon	Path&		
←	outInnerPolygons	Array<Path>&		

WKT_LoadPolygon_AsRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads polygon from WKT text format as region.

Syntax

```
void avl::WKT_LoadPolygon_AsRegion
(
 const atl::String& inText,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inText	const String&			
→	inFrameWidth	int	0 – 65535		
→	inFrameHeight	int	0 – 65535		
←	outRegion	Region&			Output region

BoxCenter

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns center of a box.

Syntax

```
void avl::BoxCenter
(
 const avl::Box& inBox,
 avl::Point2D& outCenter
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outCenter	Point2D&		

Also in AVL Lite

BoxCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a characteristic point (e.g. the top-left) of a box.

Syntax

```
void avl::BoxCharacteristicPoint
(
 const avl::Box& inBox,
 const avl::Anchor2D::Type inPointAnchor,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
→	inPointAnchor	const Anchor2D::Type	TopLeft	Selecting one of the 9 characteristic points
←	outPoint	Point2D&		

BoxCharacteristicPoints

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the characteristic points of the box.

Syntax

```
void avl::BoxCharacteristicPoints
(
 const avl::Box& inBox,
 atl::Optional<avl::Point2D&> outTopLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outTopCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outTopRight = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outMiddleRight = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomLeft = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomCenter = atl::NIL,
 atl::Optional<avl::Point2D&> outBottomRight = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outCorners = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outTopLeft	Optional<Point2D&>	NIL	
←	outTopCenter	Optional<Point2D&>	NIL	
←	outTopRight	Optional<Point2D&>	NIL	
←	outMiddleLeft	Optional<Point2D&>	NIL	
←	outMiddleCenter	Optional<Point2D&>	NIL	
←	outMiddleRight	Optional<Point2D&>	NIL	
←	outBottomLeft	Optional<Point2D&>	NIL	
←	outBottomCenter	Optional<Point2D&>	NIL	
←	outBottomRight	Optional<Point2D&>	NIL	
←	outCorners	Optional<Array<Point2D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outTopLeft**, **outTopCenter**, **outTopRight**, **outMiddleLeft**, **outMiddleCenter**, **outMiddleRight**, **outBottomLeft**, **outBottomCenter**, **outBottomRight**, **outCorners**.

Read more about Optional Outputs.

Also in AVL Lite

BoxesBoundingBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the bounding box of given boxes.

Syntax

```
void avl::BoxesBoundingBox
(
 const atl::Array<avl::Box>& inBoxes,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inBoxes	const Array<Box>&		
←	outBoundingBox	Box&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in BoxesBoundingBox.

Also in AVL Lite

BoxesBoundingBox_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the bounding box of given boxes; returns NIL if the array is empty.

Syntax

```
void avl::BoxesBoundingBox_OrNil
(
 const atl::Array<avl::Box>& inBoxes,
 atl::Conditional<avl::Box>& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inBoxes	const Array<Box>&		
←	outBoundingBox	Conditional<Box>&		

BoxIntersection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common part of two boxes.

Syntax

```
void avl::BoxIntersection
(
 const avl::Box& inBox1,
 const avl::Box& inBox2,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Default	Description
→	inBox1	const Box&		
→	inBox2	const Box&		
←	outBox	Box&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox1** and **outBox**, **inBox2** and **outBox**

Read more about In-place Computation.

Also in AVL Lite

BoxToBoxDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes minimal distance between one of the points of the first box with one of the points of the second box.

Syntax

```
void avl::BoxToBoxDistance
(
 const avl::Box& inBox1,
 const avl::Box& inBox2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox1	const Box&			
→	inBox2	const Box&			
→	inResolution	float	0.0 - ∞	1.0f	
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

CreateBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a box.

Syntax

```
void avl::CreateBox
(
 const avl::Location& inLocation,
 avl::Anchor2D::Type inLocationAnchor,
 int inWidth,
 int inHeight,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLocation	const Location&			
→	inLocationAnchor	Anchor2D::Type			
→	inWidth	int	0 – ∞		
→	inHeight	int	0 – ∞		
←	outBox	Box&			

DilateBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological dilation on a box using box kernel.

Syntax

```
void avl::DilateBox
(
 const avl::Box& inBox,
 const int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			Input box
→	inRadiusX	const int	0 – ∞	1	Horizontal radius of the box kernel
→	inRadiusY	Optional<int>	0 – ∞	NIL	Vertical radius of the box kernel
←	outBox	Box&			Dilated box

In-place Processing

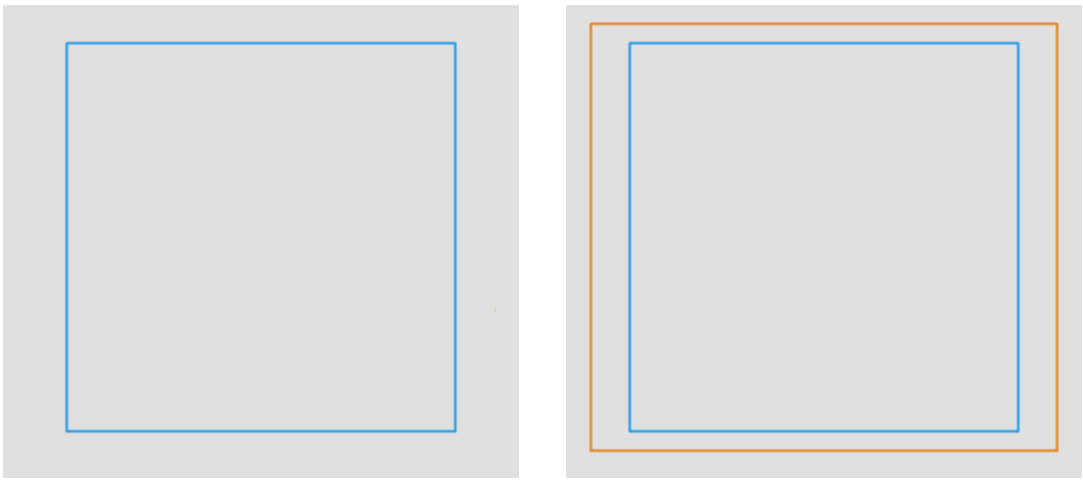
This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

Description

Performs a morphological dilation on a box using box kernel.

Examples



DilateBox *performed with kernel size 2x1.*

See Also

- ResizeBox_Relative - Resizes a box to relatively defined dimensions.
- ResizeRegion - Enlarges or shrinks a region to new dimensions.

ErodeBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological erosion on a box using box kernel.

Syntax

```
void avl::ErodeBox
(
 const avl::Box& inBox,
 const int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			Input box
→	inRadiusX	const int	0 – ∞	1	Horizontal radius of the box kernel
→	inRadiusY	Optional<int>	0 – ∞	NIL	Vertical radius of the box kernel
←	outBox	Box&			Eroded box

In-place Processing

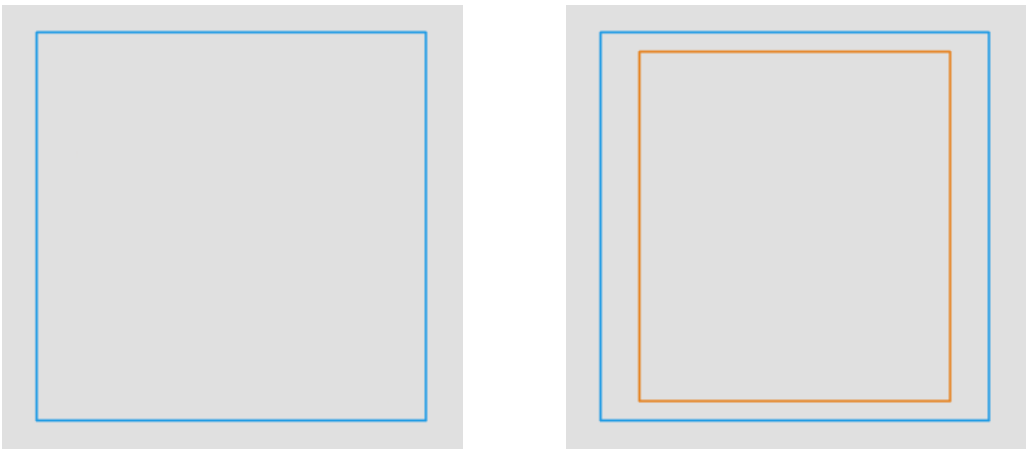
This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

Description

Performs a morphological erosion on a box using box kernel.

Examples



ErodeBox *performed with kernel size 2x1.*

See Also

- ResizeBox_Relative - Resizes a box to relatively defined dimensions.
- ResizeRegion - Enlarges or shrinks a region to new dimensions.

Also in AVL Lite

RemoveEmptyBoxes

Header: AVL.h
Namespace: avl
Module: FoundationLite

The input boxes which have both dimensions different from zero are copied to the output.

Applications: Secures against domain errors caused by empty boxes.

Syntax

```
void avl::RemoveEmptyBoxes
(
 const atl::Array<avl::Box>& inBoxes,
 atl::Array<avl::Box>& outNotEmptyBoxes,
 atl::Array<bool>& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBoxes	const Array<Box>&		
←	outNotEmptyBoxes	Array<Box>&		
←	outIsNotEmpty	Array<bool>&		

Also in AVL Lite

ResizeBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the dimensions of a box.

Syntax

```
void avl::ResizeBox
(
 const avl::Box& inBox,
 avl::Anchor2D::Type inAnchor,
 atl::Optional<int> inNewWidth,
 atl::Optional<int> inNewHeight,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			Input box
→	inAnchor	Anchor2D::Type		TopLeft	Point of the box which position will not change
→	inNewWidth	Optional<int>	0 – ∞	NIL	Target width of the box
→	inNewHeight	Optional<int>	0 – ∞	NIL	Target height of the box
←	outBox	Box&			Resized box

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

Description

The operation changes dimensions of input Box to (**inNewWidth**, **inNewHeight**).

See Also

- ResizeBox_Relative - Resizes a box to relatively defined dimensions.
- ResizeRegion - Enlarges or shrinks a region to new dimensions.

ResizeBox_Delta

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the dimensions of a box by adding some values.

Syntax

```
void avl::ResizeBox_Delta
(
 const avl::Box& inBox,
 avl::Anchor2D::Type inAnchor,
 int inWidthDelta,
 int inHeightDelta,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		Input box
→	inAnchor	Anchor2D::Type	TopLeft	Point of the box which position will not change
→	inWidthDelta	int	0	Value added to width of the box
→	inHeightDelta	int	0	Value added to height of the box
←	outBox	Box&		Resized box

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Negative box dimensions in ResizeBox_Delta.

ResizeBox_Relative

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Resizes a box to relatively defined dimensions.

Syntax

```
void avl::ResizeBox_Relative
(
 const avl::Box& inBox,
 avl::Anchor2D::Type inAnchor,
 float inHorizontalScale,
 float inVerticalScale,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			Input box
→	inAnchor	Anchor2D::Type		TopLeft	Point of the box which position will not change
→	inHorizontalScale	float	0.0 – ∞	1.0f	Scale factor of the horizontal resize
→	inVerticalScale	float	0.0 – ∞	1.0f	Scale factor of the vertical resize
←	outBox	Box&			Resized box

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

Description

The operation resizes an input box multiplying its width by **inHorizontalScale** and height by **inVerticalScale**.

See Also

- ResizeBox - Changes the dimensions of a box.
- ResizeRegion - Enlarges or shrinks a region to new dimensions.

Also in AVL Lite

SkipEmptyBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

If the input box has both dimensions different from zero, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty boxes.

Syntax

```
void avl::SkipEmptyBox
(
 const avl::Box& inBox,
 atl::Conditional<avl::Box>& outNotEmptyBox,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outNotEmptyBox	Conditional<Box>&		
←	outIsNotEmpty	bool&		

Also in AVL Lite

SplitBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Splits a box into two along a direction.

Syntax

```
void avl::SplitBox
(
 const avl::Box& inBox,
 const avl::SplitDirection::Type inSplitDirection,
 avl::Box& outBox1,
 avl::Box& outBox2
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
→	inSplitDirection	const SplitDirection::Type		
←	outBox1	Box&		
←	outBox2	Box&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox1**, **inBox** and **outBox2**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown split direction in SplitBox.

TestBoxEmpty

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether the box is empty.

Syntax

```
void avl::TestBoxEmpty
(
 const avl::Box& inBox,
 bool& outIsEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outIsEmpty	bool&		

Also in AVL Lite

TestBoxEqualTo

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether given boxes are equal.

Syntax

```
void avl::TestBoxEqualTo
(
 const avl::Box& inBox,
 const avl::Box& inReferenceBox,
 bool& outIsEqual
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
→	inReferenceBox	const Box&		
←	outIsEqual	bool&		

TestBoxInBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a box is contained in another one.

Syntax

```
void avl::TestBoxInBox
(
 const avl::Box& inSubBox,
 const avl::Box& inBox,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inSubBox	const Box&		
→	inBox	const Box&		
←	outIsContained	bool&		

Also in AVL Lite

TestBoxIntersectsWith

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether two boxes have non-empty intersection.

Syntax

```
void avl::TestBoxIntersectsWith
(
 const avl::Box& inBox,
 const avl::Box& inReferenceBox,
 bool& outBoxesIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
→	inReferenceBox	const Box&		
←	outBoxesIntersect	bool&		

TestBoxNotEmpty

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether the box is not empty.

Syntax

```
void avl::TestBoxNotEmpty
(
 const avl::Box& inBox,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		
←	outIsNotEmpty	bool&		

Also in AVL Lite

TranslateBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shifts a box by a discreet vector.

Syntax

```
void avl::TranslateBox
(
 const avl::Box& inBox,
 int inDeltaX,
 int inDeltaY,
 bool inInverse,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Default	Description
→	inBox	const Box&		Input box
→	inDeltaX	int		Shift along the x axis
→	inDeltaY	int		Shift along the y axis
→	inInverse	bool		Switches to inverse operation
←	outBox	Box&		Shifted box

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inBox** and **outBox**

Read more about In-place Computation.

45. Geometry 3D Basics

Table of content:

- CreateBox3D
- CreateSegment3D
- LoadPoint3DArrayFromTextFile
- RandomPoint3D
- SkipEmptyBox3D
- TestBox3DEmpty
- TestBox3DInBox3D
- TestBox3DIntersectsWith
- TestBox3DNotEmpty

CreateBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Creates a box in 3D.

Syntax

```
void avl::CreateBox3D
(
 const avl::Point3D& inPoint3D,
 const avl::Anchor3D& inPoint3DAnchor3D,
 float inXLength,
 float inYLength,
 float inZLength,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3D	const Point3D&			
→	inPoint3DAnchor3D	const Anchor3D&			
→	inXLength	float	0.0 – ∞		
→	inYLength	float	0.0 – ∞		
→	inZLength	float	0.0 – ∞		
←	outBox3D	Box3D&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid Anchor3D in CreateBox3D.

CreateSegment3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Produces a segment in 3D of given parameters.

Syntax

```
void avl::CreateSegment3D
(
 const avl::Point3D& inPoint3D,
 float inPointAnchor,
 const avl::Vector3D& inDirectionVector,
 float inLength,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3D	const Point3D&			A point on the created segment
→	inPointAnchor	float	0.0 – 1.0		Anchor point, 0 means the beginning, 1 means the end of the segment
→	inDirectionVector	const Vector3D&			Desired direction of the segment
→	inLength	float			Desired length of the segment in pixels
←	outSegment3D	Segment3D&			The resulting segment

LoadPoint3DArrayFromTextFile

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Loads arrays of 3D points from text file.

Syntax

```
void avl::LoadPoint3DArrayFromTextFile
(
 const atl::File& inFile,
 const avl::Grid3DFileFormat::Type inFileFormat,
 const atl::String& inSplitters,
 const int inLineSkip,
 atl::Array<avl::Point3D>& outPoints,
 atl::String& diagTextLine,
 avl::Point3D& diagExtractedValues
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
→	inFileFormat	const Grid3DFileFormat::Type		
→	inSplitters	const String&		Characters ignored between numbers, space is always splitter and ignored in file sequence
→	inLineSkip	const int	0	Number of first lines to skip
←	outPoints	Array<Point3D>&		
🔍	diagTextLine	String&		First valid parse line
🔍	diagExtractedValues	Point3D&		Example of expected line

Errors

List of possible exceptions:

Error type	Description
DomainError	Splitters should do not contains any spaces in Load3DPointArrayFromTextFile.
IoError	Unable to open file in Load3DPointArrayFromTextFile.

RandomPoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Creates random 3D point inside given box.

Syntax

```
void avl::RandomPoint3D
(
 RandomState& ioState,
 const avl::Box3D& inBox3D,
 atl::Optional<int> inSeed,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RandomState&		Object used to maintain state of the function.
→	inBox3D	const Box3D&		Bounding box of generated point
→	inSeed	Optional<int>	NIL	Random seed
←	outPoint3D	Point3D&		

SkipEmptyBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

If the input box in 3D has all dimensions different from zero, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty boxes.

Syntax

```
void avl::SkipEmptyBox3D
(
 const avl::Box3D& inBox3D,
 atl::Conditional<avl::Box3D>& outNotEmptyBox3D,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
←	outNotEmptyBox3D	Conditional<Box3D>&		
←	outIsNotEmpty	bool&		

TestBox3DEmpty

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether the box in 3D is empty.

Syntax

```
void avl::TestBox3DEmpty
(
 const avl::Box3D& inBox3D,
 bool& outIsEmpty
)
```

Parameters

	Name	Type	Default	Description
➡	inBox3D	const Box3D&		
⬅	outIsEmpty	bool&		

TestBox3DInBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether a box in 3D is contained in another one.

Syntax

```
void avl::TestBox3DInBox3D
(
 const avl::Box3D& inSubBox3D,
 const avl::Box3D& inBox3D,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
➡	inSubBox3D	const Box3D&		
➡	inBox3D	const Box3D&		
⬅	outIsContained	bool&		

TestBox3DIntersectsWith

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether two boxes in 3D have non-empty intersection.

Syntax

```
void avl::TestBox3DIntersectsWith
(
 const avl::Box3D& inBox3D,
 const avl::Box3D& inReferenceBox3D,
 bool& outBoxes3DIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
→	inReferenceBox3D	const Box3D&		
←	outBoxes3DIntersect	bool&		

TestBox3DNotEmpty

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether the box in 3D is not empty.

Syntax

```
void avl::TestBox3DNotEmpty
(
 const avl::Box3D& inBox3D,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
←	outIsNotEmpty	bool&		

46. Histogram Basics

Table of content:

- ConvertToCumulativeHistogram
- CreateHistogram
- CreateUniformHistogram
- GetHistogramBin
- GetHistogramCorrespondingBin
- HistogramIndices
- SetHistogramBin
- SetHistogramCorrespondingBin
- SkipEmptyDataHistogram
- SkipEmptyHistogram

ConvertToCumulativeHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the cumulative histogram of input histogram.

Syntax

```
void avl::ConvertToCumulativeHistogram
(
 const avl::Histogram& inHistogram,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outHistogram	Histogram&		Output histogram

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inHistogram** and **outHistogram**

Read more about In-place Computation.

CreateHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates the histogram of the array of real numbers.

Syntax

```
void avl::CreateHistogram
(
 const atl::Array<float>& inArray,
 atl::Optional<const atl::Array<double>&> inWeights,
 atl::Optional<float> inDomainStart,
 const float inBinSize,
 atl::Optional<int> inBinCount,
 const bool inCyclic,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Range	Default	Description
→	inArray	const Array<float>&			Array from which histogram will be generated
→	inWeights	Optional<const Array<double>&>		NIL	Weights corresponding to the elements of 'inArray'
→	inDomainStart	Optional<float>		NIL	Input domain begin
→	inBinSize	const float	0.0001 – ∞	1.0f	Input bin size
→	inBinCount	Optional<int>	0 – + ∞	NIL	Input domain length
→	inCyclic	const bool		False	Determines if input data is cyclic
←	outHistogram	Histogram&			Output histogram

Description

The operation creates a histogram of **inArray** values.

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent array lengths at inArray and inWeights in CreateHistogram.
DomainError	Input bin width is incorrect in CreateHistogram.
DomainError	Input boundaries are incorrect in CreateHistogram.
DomainError	Negative weight encountered in CreateHistogram.
DomainError	Output histogram size too large in CreateHistogram.

See Also

- ImageHistogram – Computes the histogram of the image pixel values.

CreateUniformHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a uniform histogram of desired parameters with common value of all bins.

Syntax

```
void avl::CreateUniformHistogram
(
 double inValue,
 float inDomainStart,
 float inBinSize,
 int inBinCount,
 avl::Histogram& outHistogram
)
```

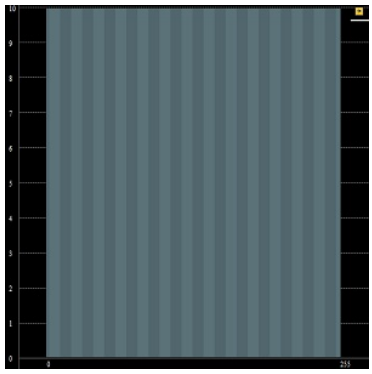
Parameters

	Name	Type	Range	Default	Description
→	inValue	double			Common value for all bins of the constructed histogram
→	inDomainStart	float		0.0f	First value of the domain represented by the histogram
→	inBinSize	float	0.0 – ∞	1.0f	Length of the domain section represented by each bin
→	inBinCount	int	1 – + ∞	1	Length of the domain represented by the histogram
←	outHistogram	Histogram&			The resulting histogram

Description

The operation creates a histogram composed from equally valued bins representing the given domain.

Examples



CreateUniformHistogram *run with* ***inValue*** *= 10.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Non-positive bin width in CreateUniformHistogram.

See Also

- ImageHistogram – Computes the histogram of the image pixel values.
- MakeHistogram – Creates a histogram out of an array of bin values.

GetHistogramBin

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the value of a single histogram bin.

Syntax

```
void avl::GetHistogramBin
(
 const avl::Histogram& inHistogram,
 int inIndex,
 const bool inCyclic,
 const bool inInverse,
 double& outValue,
 atl::Optional<float&> outBinStart = atl::NIL,
 atl::Optional<float&> outBinEnd = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inIndex	int		Input bin index
→	inCyclic	const bool	False	Whether to wrap the index around or not
→	inInverse	const bool		Reversed order of bins
←	outValue	double&		Output value of the bin
←	outBinStart	Optional<float&>	NIL	Lower limit of the bin
←	outBinEnd	Optional<float&>	NIL	Upper limit of the bin

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBinStart**, **outBinEnd**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect index on input in GetHistogramBin.

GetHistogramCorrespondingBin

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects a bin that the given value in the histogram domain falls into and returns the value of this bin.

Syntax

```
void avl::GetHistogramCorrespondingBin
(
 const avl::Histogram& inHistogram,
 float inBinSelectionValue,
 const bool inCyclic,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inBinSelectionValue	float		Input value in the histogram domain that will be used to select the bin
→	inCyclic	const bool	False	Whether to wrap the index around or not
←	outValue	double&		Output value of the bin

Errors

List of possible exceptions:

Error type	Description
DomainError	inBinSelectionValue exceeds the histogram domain in GetHistogramCorrespondingBin.

HistogramIndices

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns an array of histogram elements' indices.

Syntax

```
void avl::HistogramIndices
(
 const avl::Histogram& inHistogram,
 atl::Array<int>& outIndices
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outIndices	Array<int>&		

SetHistogramBin

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Sets the value of a single histogram bin.

Syntax

```
void avl::SetHistogramBin
(
 avl::Histogram& ioHistogram,
 int inIndex,
 const bool inCyclic,
 const bool inInverse,
 double inNewValue
)
```

Parameters

	Name	Type	Default	Description
	ioHistogram	Histogram&		
	inIndex	int		Input bin index
	inCyclic	const bool	False	Whether to wrap the index around or not
	inInverse	const bool		Reversed order of bins
	inNewValue	double		Input new value to be set

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect index on input in SetHistogramBin.

SetHistogramCorrespondingBin

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects a bin that the given value in the histogram domain falls into and sets the value of this bin.

Syntax

```
void avl::SetHistogramCorrespondingBin
(
 avl::Histogram& ioHistogram,
 float inBinSelectionValue,
 const bool inCyclic,
 double inNewValue
)
```

Parameters

	Name	Type	Default	Description
⇄	ioHistogram	Histogram&		
→	inBinSelectionValue	float		Input value in the histogram domain that will be used to select the bin
→	inCyclic	const bool	False	Whether to wrap the index around or not
→	inNewValue	double		Input new value to be set

Errors

List of possible exceptions:

Error type	Description
DomainError	inBinSelectionValue exceeds the histogram domain in SetHistogramCorrespondingBin.

SkipEmptyDataHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

If the input histogram contains any non-zero bin, then the histogram is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by histograms representing empty data sets, e.g. just before the HistogramDataAverage filter is to be invoked.

Syntax

```
void avl::SkipEmptyDataHistogram
(
 const avl::Histogram& inHistogram,
 atl::Conditional<avl::Histogram>& outNotEmptyDataHistogram,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outNotEmptyDataHistogram	Conditional<Histogram>&		
←	outIsNotEmpty	bool&		

SkipEmptyHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

If the input histogram contains at least one bin, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty histograms, e.g. just before the HistogramAverage filter is to be invoked.

Syntax

```
void avl::SkipEmptyHistogram
(
 const avl::Histogram& inHistogram,
 atl::Conditional<avl::Histogram>& outNotEmptyHistogram,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outNotEmptyHistogram	Conditional<Histogram>&		The histogram, if it is not empty
←	outIsNotEmpty	bool&		Indication if the input histogram is not empty

ClearImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets image pixels in ROI to the specified value.

Syntax

```
void avl::ClearImage
(
 avl::Image& ioImage,
 atl::Optional<const avl::Region&> inRegion,
 const avl::Pixel& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inRegion	Optional<const Region&>	NIL	Input region
	inValue	const Pixel&		The new background color

See Also

- DrawRegion – Draws a region on an image.
- DrawRegions_SingleColor – Draws regions on an image with a single color.
- FillImage – Fills the input image with one color.

Also in AVL Lite

CopyImageData

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image copy with the same size and pixel format.

Syntax

```
void avl::CopyImageData
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	inImage	const Image&		Input image
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CopyImageData.

CopyPixels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Copies pixels from one image to another.

Syntax

```
void avl::CopyPixels
(
 avl::Image& ioImage,
 const avl::Region& inRoi,
 const avl::Image& inSourceImage
)
```

Parameters

	Name	Type	Default	Description
↔	ioImage	Image&		
→	inRoi	const Region&		Range of pixels to be processed
→	inSourceImage	const Image&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Different image formats in CopyPixels.
DomainError	Different image sizes in CopyPixels.

CreateImageFromPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Creates a depth image from the Z-values of the input point grid.

Applications: Allows for performing 2D operations on 3D data.

Syntax

```
void avl::CreateImageFromPoint3DGrid
(
 const avl::Point3DGrid& inPoint3DGrid,
 const float inMissingPointValue,
 const float inPixelOffset,
 const float inPixelScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid	const Point3DGrid&			
→	inMissingPointValue	const float			Value assigned to pixels where point is undefined
→	inPixelOffset	const float		0.0f	Value added to every pixel
→	inPixelScale	const float	$-\infty$ $-\infty$	1.0f	Value every pixel is multiplied by
←	outImage	Image&			Output image

CreateImageFromSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a depth image from the Z-values of the input surface.

Applications: Allows for performing 2D operations on 3D data.

Syntax

```
void avl::CreateImageFromSurface
(
 const avl::Surface& inSurface,
 avl::PlainType::Type inPixelType,
 avl::ResampleSurfaceMode::Type inResampleSurfaceMode,
 atl::Optional<double> inXOffset,
 atl::Optional<double> inYOffset,
 atl::Optional<double> inPixelOffset,
 atl::Optional<double> inPixelScale,
 atl::Optional<float> inMissingPointValue,
 avl::Image& outImage,
 atl::Optional<avl::SurfaceFormat&> outSurfaceFormat = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inPixelType	PlainType::Type		Real	Output image pixel type
→	inResampleSurfaceMode	ResampleSurfaceMode::Type			
→	inXOffset	Optional<double>		NIL	Offset for the X axis of the output image; if set to Nil, surface X offset is chosen
→	inYOffset	Optional<double>		NIL	Offset for the Y axis of the output image; if set to Nil, surface Y offset is chosen
→	inPixelOffset	Optional<double>		NIL	Offset that the input surface values have in the output image; if set to Nil, surface Z offset is chosen
→	inPixelScale	Optional<double>	0.0D – ∞	1.0D	Scale that the input surface values have in the output image; if set to Nil, surface Z scale is chosen
→	inMissingPointValue	Optional<float>		0.0f	Value assigned to pixels where point is undefined
←	outImage	Image&			Input surface depth image
←	outSurfaceFormat	Optional<SurfaceFormat&>		NIL	Format of the surface that the output image represents

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceFormat**.

Read more about Optional Outputs.

CreateImageFromSurface_AnyScales

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a depth image from the Z-values of the input surface.

Applications: Allows for performing 2D operations on 3D data.

Syntax

```
void avl::CreateImageFromSurface_AnyScales
(
 const avl::Surface& inSurface,
 avl::PlainType::Type inPixelType,
 atl::Optional<double> inXOffset,
 atl::Optional<double> inXScale,
 atl::Optional<double> inYOffset,
 atl::Optional<double> inYScale,
 atl::Optional<double> inPixelOffset,
 atl::Optional<double> inPixelScale,
 atl::Optional<float> inMissingPointValue,
 avl::Image& outImage,
 atl::Optional<avl::SurfaceFormat&> outSurfaceFormat = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inPixelType	PlainType::Type		Real	Output image pixel type
→	inXOffset	Optional<double>		NIL	Offset for the X axis of the output image; if set to Nil, surface X offset is chosen
→	inXScale	Optional<double>	0.000001D – ∞	NIL	Scale for the X axis of the output image; if set to Nil, surface X scale is chosen
→	inYOffset	Optional<double>		NIL	Offset for the Y axis of the output image; if set to Nil, surface Y offset is chosen
→	inYScale	Optional<double>	0.000001D – ∞	NIL	Scale for the Y axis of the output image; if set to Nil, surface Y scale is chosen
→	inPixelOffset	Optional<double>		NIL	Offset that the input surface values have in the output image; if set to Nil, surface Z offset is chosen
→	inPixelScale	Optional<double>	0.0D – ∞	1.0D	Scale that the input surface values have in the output image; if set to Nil, surface Z scale is chosen
→	inMissingPointValue	Optional<float>		0.0f	Value assigned to pixels where point is undefined
←	outImage	Image&			Input surface depth image
←	outSurfaceFormat	Optional<SurfaceFormat&>		NIL	Format of the surface that the output image represents

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSurfaceFormat**.

Read more about Optional Outputs.

EmptyImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image filled with one color.

Applications: Most typically used to prepare a background for image drawing tools.

Syntax

```
void avl::EmptyImage
(
 const int inWidth,
 const int inHeight,
 const avl::Pixel& inColor,
 const int inChannels,
 const avl::PlainType::Type& inPixelType,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inWidth	const int	1 – 65535	320	Width of the created image
→	inHeight	const int	1 – 65535	240	Height of the created image
→	inColor	const Pixel&			Color of all pixels of the created image
→	inChannels	const int	1 – 4	3	Number of channels
→	inPixelType	const PlainType::Type&		UInt8	
←	outImage	Image&			Output image

Description

The operation produces an empty image of desired dimensions and color.

Examples

EmptyImage *run with default parameters produces 320x240 black image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Also in AVL Lite

FillImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Fills the input image with one color.

Syntax

```
void avl::FillImage
(
 avl::Image& ioImage,
 const avl::Pixel& inColor
)
```

Parameters

	Name	Type	Default	Description
↔	ioImage	Image&		
→	inColor	const Pixel&		Color of all pixels of the created image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- ClearImage – Sets image pixels in ROI to the specified value.

Also in AVL Lite

GetImageColumn

Header: AVL.h
Namespace: avl
Module: FoundationLite

Extracts an array of pixel values from a single column of an image.

Syntax

```
void avl::GetImageColumn
(
 const avl::Image& inImage,
 atl::Optional<int> inChannelIndex,
 const int inColumnIndex,
 atl::Array<float>& outValues,
 atl::Array<avl::Pixel>& outPixels
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inChannelIndex	Optional<int>	0 – 3	NIL	Selects a channel of the input image
→	inColumnIndex	const int	0 – 65535		Selects a column of the input image
←	outValues	Array<float>&			Output pixel values of the column
←	outPixels	Array<Pixel>&			Output pixels of the column

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index out of range in GetImageColumn.
DomainError	Column index out of range in GetImageColumn.

Also in AVL Lite

GetImageData

Header: AVL.h
Namespace: avl
Module: FoundationLite

Extracts the image content (raw pixel data) as a binary buffer.

Syntax

```
void avl::GetImageData
(
 const avl::Image& inImage,
 atl::Optional<int> inPitch,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inPitch	Optional<int>	0 – ∞	NIL	Length, in bytes, between starts of consecutive image rows for the resulting data
←	outBuffer	ByteBuffer&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Pitch value is too small for the source image width and pixel format.
RuntimeError	Invalid image format in GetImageData.
RuntimeError	Resulting byte buffer size is too large.

Also in AVL Lite

GetImagePixel

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a single pixel of an image.

Syntax

```
void avl::GetImagePixel
(
 const avl::Image& inImage,
 const avl::Location& inLocation,
 avl::Pixel& outPixel,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inLocation	const Location&		Location of the pixel to be accessed
←	outPixel	Pixel&		Output pixel
←	outValue	float&		Average pixel value

Errors

List of possible exceptions:

Error type	Description
DomainError	Input location exceeds dimensions of an input image in GetImagePixel.

GetImagePixel_Interpolated

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns an interpolated single pixel of an image.

Applications: Sub-pixel sampling of an image.

Syntax

```
void avl::GetImagePixel_Interpolated
(
 const avl::Image& inImage,
 const avl::Point2D& inPoint,
 avl::InterpolationMethod::Type inInterpolation,
 avl::Pixel& outPixel,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPoint	const Point2D&		Point on the input image to be accessed
→	inInterpolation	InterpolationMethod::Type	Bilinear	
←	outPixel	Pixel&		Output pixel
←	outValue	float&		Average pixel value

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point exceeds dimensions of an input image in GetImagePixel_Interpolated.
DomainError	Unknown interpolation method in GetImagePixel_Interpolated.

GetImageRow

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Extracts an array of pixel values from a single row of an image.

Syntax

```
void avl::GetImageRow
(
 const avl::Image& inImage,
 atl::Optional<int> inChannelIndex,
 const int inRowIndex,
 atl::Array<float>& outValues,
 atl::Array<avl::Pixel>& outPixels
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inChannelIndex	Optional<int>	0 – 3	NIL	Selects a channel of the input image
→	inRowIndex	const int	0 – 65535		Selects a row of the input image
←	outValues	Array<float>&			Output pixel values of the row
←	outPixels	Array<Pixel>&			Output pixels of the row

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index out of range in GetImageRow.
DomainError	Row index out of range in GetImageRow.

Also in AVL Lite

GetMultipleImagePixelValues_Safe

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns an array of pixel values at specified locations; the image range is checked.

Syntax

```
void avl::GetMultipleImagePixelValues_Safe
(
 const avl::Image& inImage,
 const atl::Array<avl::Point2D>& inPoints,
 const avl::InterpolationMethod::Type inInterpolation,
 float inDefault,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPoints	const Array<Point2D>&		
→	inInterpolation	const InterpolationMethod::Type	Bilinear	
→	inDefault	float	0.0f	
←	outValues	Array<float>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown interpolation method in GetMultipleImagePixelValues_Safe.

Also in AVL Lite

ImageBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a box corresponding to the dimensions of an image.

Syntax

```
void avl::ImageBox
(
 const avl::Image& inImage,
 avl::Box& outBox
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outBox	Box&		Output box

Also in AVL Lite

ImageCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns one of the 9 characteristic points of an image (corners or mid-points).

Syntax

```
void avl::ImageCharacteristicPoint
(
 const avl::Image& inImage,
 const avl::Anchor2D::Type inPointAnchor,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPointAnchor	const Anchor2D::Type	TopLeft	Selecting one of the 9 characteristic points
←	outPoint	Point2D&		

Also in AVL Lite

ImageToMatrix

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a single-channel image to a matrix.

Syntax

```
void avl::ImageToMatrix
(
 const avl::Image& inMonoImage,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMonoImage	const Image&		
←	outMatrix	Matrix&		

Requirements

For input **inMonoImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inMonoImage pixel format in ImageToMatrix. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

JoinProfilesIntoImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image by joining an array of 1D profiles into consecutive image rows.

Applications: Usually used for merging 3D profiles into a depth image.

Syntax

```
void avl::JoinProfilesIntoImage
(
 const atl::Array<avl::Profile>& inProfiles,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inProfiles	const Array<Profile>&		
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles do not have the same sizes in JoinProfilesIntoImage.
DomainError	Input profiles have different X coordinates in JoinProfilesIntoImage.

JoinProfilesIntoImage_OfSeries

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image by joining 1D profiles, which appear in consecutive iterations.

Applications: Usually used for merging 3D profiles into a depth image.

Syntax

```
void avl::JoinProfilesIntoImage_OfSeries
(
 JoinProfilesIntoImage_OfSeriesState& ioState,
 const avl::Profile& inProfile,
 const int inSeriesSize,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	JoinProfilesIntoImage_OfSeriesState&			Object used to maintain state of the function.
→	inProfile	const Profile&			Input profile
→	inSeriesSize	const int	1 – ∞		Number of profiles that constitute a single image
←	outImage	Conditional<Image>&			A depth image every inSeriesSize iterations, or Nil in all other iterations

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles do not have the same sizes in JoinProfilesIntoImage_OfSeries.

LoadImageObject

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads serialized Image object from AVDATA file.

Syntax

```
void avl::LoadImageObject
(
 const atl::File& inFilename,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outImage	Image&		Deserialized output Image

Also in AVL Lite

MatrixToImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a matrix to a single-channel real image.

Syntax

```
void avl::MatrixToImage
(
 const avl::Matrix& inMatrix,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
←	outImage	Image&		Output image

Also in AVL Lite

RealignImagePitch

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a new image with a standard pitch alignment.

Applications: Can be used to normalize an image created with a non-standard third-party camera or framegrabber.

Syntax

```
void avl::RealignImagePitch
(
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty image on input in RealignImagePitch.

Also in AVL Lite

SaveImageObject

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves serialized Image object as AVDATA file.

Syntax

```
void avl::SaveImageObject
(
 const avl::Image& inImage,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image to be serialized
→	inFilename	const File&		Name of the target file

SetImageColumn

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets pixel values in a single entire column of an image.

Applications: Allows for creating images from calculated real values. It is significantly slower than SetImageRow.

Syntax

```
void avl::SetImageColumn
(
 avl::Image& ioImage,
 atl::Optional<int> inChannelIndex,
 const int inColumnIndex,
 const atl::Array<float>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inChannelIndex	Optional<int>	0 – 3	NIL	Selects a channel of the input image
	inColumnIndex	const int	0 – 65535		Selects a column of the input image
	inValues	const Array<float>&			New values for specified column

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index out of range in SetImageColumn.
DomainError	Column index out of range in SetImageColumn.
DomainError	Size of inValues array and image height are not equal in SetImageColumn.

Also in AVL Lite

SetImagePixel

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets a pixel of an image to the selected value.

Syntax

```
void avl::SetImagePixel
(
 avl::Image& ioImage,
 const avl::Location& inLocation,
 const avl::Pixel& inPixel
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inLocation	const Location&		Location of the pixel to be set
	inPixel	const Pixel&		New pixel value

Errors

List of possible exceptions:

Error type	Description
DomainError	Input location exceeds dimensions of an input image in SetImagePixel.

Also in AVL Lite

SetImagePixels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets multiple pixels of an image to the selected value (all the pixels get the same value).

Syntax

```
void avl::SetImagePixels
(
 avl::Image& ioImage,
 const atl::Array<avl::Location>& inLocations,
 const avl::Pixel& inPixel
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inLocations	const Array<Location>&		Locations of the pixels to be set
	inPixel	const Pixel&		New pixel value

Errors

List of possible exceptions:

Error type	Description
DomainError	Input location exceeds dimensions of an input image in SetImagePixels.

SetImageRow

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets pixel values in a single entire row of an image.

Applications: Allows for creating images from calculated real values.

Syntax

```
void avl::SetImageRow
(
 avl::Image& ioImage,
 atl::Optional<int> inChannelIndex,
 const int inRowIndex,
 const atl::Array<float>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inChannelIndex	Optional<int>	0 – 3	NIL	Selects a channel of the input image
	inRowIndex	const int	0 – 65535		Selects a row of the input image
	inValues	const Array<float>&			New values for specified row

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index out of range in SetImageRow.
DomainError	Row index out of range in SetImageRow.
DomainError	Size of inValues array and image width are not equal in SetImageRow.

SetMultipleImagePixels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sets pixels of an image to the selected values (each pixel gets another value).

Syntax

```
void avl::SetMultipleImagePixels
(
 avl::Image& ioImage,
 const atl::Array<avl::Location>& inLocations,
 const atl::Array<avl::Pixel>& inPixels
)
```

Parameters

	Name	Type	Default	Description
⇆	ioImage	Image&		
→	inLocations	const Array<Location>&		Locations of the pixels to be set
→	inPixels	const Array<Pixel>&		New pixel values

Errors

List of possible exceptions:

Error type	Description
DomainError	Input location exceeds dimensions of an input image in SetMultipleImagePixels.

SkipEmptyImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

If the input image contains at least one pixel, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty images.

Syntax

```
void avl::SkipEmptyImage
(
 const avl::Image& inImage,
 atl::Conditional<avl::Image>& outNotEmptyImage,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outNotEmptyImage	Conditional<Image>&		
←	outIsNotEmpty	bool&		

TestImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a sample image.

Applications: Makes it possible to quickly present results of various image processing filters.

Syntax

```
void avl::TestImage
(
 avl::TestImageId::Type inImageId,
 atl::Optional<avl::Image&> outRgbImage = atl::NIL,
 atl::Optional<avl::Image&> outMonoImage = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImageId	TestImageId::Type		ID of test image
←	outRgbImage	Optional<Image&>	NIL	Output color image
←	outMonoImage	Optional<Image&>	NIL	Output mono image

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRgbImage**, **outMonoImage**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	This image is not available in your region.

48. Location

Table of content:

- LocationCenter
- TranslateLocation

Also in AVL Lite

LocationCenter

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the center point of a pixel indicated by the provided location.

Syntax

```
void avl::LocationCenter
(
 const avl::Location& inLocation,
 avl::Point2D& outCenter
)
```

Parameters

	Name	Type	Default	Description
→	inLocation	const Location&		Pixel location.
←	outCenter	Point2D&		Center point of the provided pixel.

Also in AVL Lite

TranslateLocation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shifts a Location by a given number of pixels along each axis.

Syntax

```
void avl::TranslateLocation
(
 const avl::Location& inLocation,
 int inDeltaX,
 int inDeltaY,
 bool inInverse,
 avl::Location& outLocation
)
```

Parameters

	Name	Type	Default	Description
→	inLocation	const Location&		Input location
→	inDeltaX	int		Shift along the x axis
→	inDeltaY	int		Shift along the y axis
→	inInverse	bool		Switches to inverse operation
←	outLocation	Location&		Shifted location

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inLocation** and **outLocation**

Read more about In-place Computation.

49. Point3DGrid Basics

Table of content:

- CreatePoint3DGridFromImage
- GetPoint3DGridPoint_Interpolated
- SkipEmptyPoint3DGrid
- TestPoint3DGrid

CreatePoint3DGridFromImage

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a Point3DGrid structure from coordinates encoded in pixels of image.

Applications: Creating a Point3DGrid structure out of an image obtained from a 3D camera or other external sources that encodes point cloud XYZ coordinates as pixel components of 2D image.

Syntax

```
void avl::CreatePoint3DGridFromImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::PointCloudCoordinateTransform& inXCoordinateTransform,
 const avl::PointCloudCoordinateTransform& inYCoordinateTransform,
 const avl::PointCloudCoordinateTransform& inZCoordinateTransform,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Source image with per pixel encoded XYZ coordinates
→	inRoi	Optional<const Region&>	NIL	Region determining valid points in resulting point grid
→	inXCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 0 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the X coordinate
→	inYCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 1 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the Y coordinate
→	inZCoordinateTransform	const PointCloudCoordinateTransform&	PointCloudCoordinateTransform (Offset: 0.000000D ValueCoordinateTransform: ImageValueCoordinateTransform(ChannelIndex: 2 Scale: 1.0D InvalidValues: Nil) LocationCoordinateTransform: Nil Limits: ValueLimits_f64(MinValue: Nil, MaxValue: Nil))	Description of the creation of the Z coordinate
←	outPoint3DGrid	Point3DGrid&		

Description

The operation creates a point cloud object based on the input point image. Coordinates of points included in the cloud are created based on **inXCoordinateTransform**, **inYCoordinateTransform** and **inYCoordinateTransform**. The listed structures describe the transformation of pixel values and their indexes to a given coordinate. At least one of the transforms based on pixel location or value must be present in PointCloudCoordinateTransform.

Example for the coordination of x. We assume that inXCoordinateTransform.locationCoordinateTransform and inXCoordinateTransform.valueCoordinateTransform are not empty. Empty transformation will be skipped.

New value of pixel is given by:

$$P_0 = scale_{value} * value_{channel} + scale_{row} * i + scale_{column} * j + offset$$

where

- $scale_{value}$ is inXCoordinateTransform.valueCoordinateTransform.scale
- $value_{channel}$ is image pixel channel value, when channel is inXCoordinateTransform.valueCoordinateTransform.channelIndex
- $scale_{row}$ is inXCoordinateTransform.locationCoordinateTransform.rowScale
- $scale_{column}$ is inXCoordinateTransform.locationCoordinateTransform.columnScale
- i is pixel row index
- j is pixel column index
- $offset$ is inXCoordinateTransform.offset

InvalidValues are checked based on direct pixel value.

Limits are applied to the final, transformed 3D point.

Errors

List of possible exceptions:

Error type	Description
DomainError	Channel index from inXCoordinateTransform is bigger than image channel count in CreatePoint3DGridFromImage.
DomainError	Channel index from inYCoordinateTransform is bigger than image channel count in CreatePoint3DGridFromImage.
DomainError	Channel index from inZCoordinateTransform is bigger than image channel count in CreatePoint3DGridFromImage.
DomainError	PointCloudCoordinateTransform requires at least one non-empty X coordinate transform in CreatePoint3DGridFromImage.
DomainError	PointCloudCoordinateTransform requires at least one non-empty Y coordinate transform in CreatePoint3DGridFromImage.
DomainError	PointCloudCoordinateTransform requires at least one non-empty Z coordinate transform in CreatePoint3DGridFromImage.

GetPoint3DGridPoint_Interpolated

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns an interpolated single point of a point 3D grid.

Syntax

```
void avl::GetPoint3DGridPoint_Interpolated
(
 const avl::Point3DGrid& inPoint3DGrid,
 float inOffsetX,
 float inOffsetY,
 float inStepX,
 float inStepY,
 float inX,
 float inY,
 int inInterpolationRadius,
 avl::Point3D& outPoint
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3DGrid	const Point3DGrid&			Input point 3D grid
→	inOffsetX	float			Defines offset of the input grid along X axis
→	inOffsetY	float			Defines offset of the input grid along Y axis
→	inStepX	float	0.01 – ∞	1.0f	Defines step of the input grid along X axis
→	inStepY	float	0.01 – ∞	1.0f	Defines step of the input grid along Y axis
→	inX	float			X coordinate of the input point
→	inY	float			Y coordinate of the input point
→	inInterpolationRadius	int	0 – 65535	1	Radius of vicinity taking into account to interpolate not existing point
←	outPoint	Point3D&			Output point

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect input coordinates in GetPoint3DGridPoint_Interpolated.

SkipEmptyPoint3DGrid

Header: AVL.h
Namespace: avl
Module: Vision3DLite

If the input Point3DGrid has at least one point defined, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty grids, e.g. just before the FitPlaneToPoints filter is to be invoked.

Syntax

```
void avl::SkipEmptyPoint3DGrid
(
 const avl::Point3DGrid& inPoint3DGrid,
 atl::Conditional<avl::Point3DGrid>& outNotEmptyPoint3DGrid,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
←	outNotEmptyPoint3DGrid	Conditional<Point3DGrid>&		A copy of the input grid, if it is not empty, or Nil otherwise
←	outIsNotEmpty	bool&		Indication if the input grid is not empty

TestPoint3DGrid

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a sample 3D object.

Syntax

```
void avl::TestPoint3DGrid
(
 TestPoint3DGridState& ioState,
 const float inDensity,
 const float inScaleX,
 const float inScaleY,
 const float inScaleZ,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	TestPoint3DGridState&			Object used to maintain state of the function.
→	inDensity	const float	1.0 – 20.0	4.0f	Density of points in output object
→	inScaleX	const float	0.001 – ∞	1.0f	Scaling of output object on X axis
→	inScaleY	const float	0.001 – ∞	1.0f	Scaling of output object on Y axis
→	inScaleZ	const float	0.001 – ∞	1.0f	Scaling of output object on Z axis
←	outPoint3DGrid	Point3DGrid&			Output object

50. Profile Basics

Table of content:

- CreateUniformProfile
- GetProfileElement
- GetProfileElement_Interpolated
- GetProfileValue
- ProfileCoordinates
- ProfileIndices
- SetProfileElement
- SetProfileXTransform
- SkipEmptyProfile

CreateUniformProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a profile with all its elements set to the same value.

Syntax

```
void avl::CreateUniformProfile
(
 float inValue,
 int inSize,
 float inXOffset,
 float inXScale,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValue	float			Input common value of all elements
→	inSize	int	0 – +∞	1	Input the number of elements
→	inXOffset	float		0.0f	X offset of the output profile
→	inXScale	float	0.001 – ∞	1.0f	X scale of the output profile
←	outProfile	Profile&			Output profile

GetProfileElement

Header: AVL.h
Namespace: avl
Module: FoundationPro

Gets a single value from a profile, located at the specified index.

Syntax

```
void avl::GetProfileElement
(
 const avl::Profile& inProfile,
 const int inIndex,
 const bool inInverse,
 float& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inIndex	const int	0 – ∞		
→	inInverse	const bool			Reversed order of elements
←	outValue	float&			

Errors

List of possible exceptions:

Error type	Description
DomainError	inIndex is out of profile range in GetProfileElement.

GetProfileElement_Interpolated

Header: AVL.h
Namespace: avl
Module: FoundationPro

Gets a single value from a profile, interpolated at any point.

Syntax

```
void avl::GetProfileElement_Interpolated
(
 const avl::Profile& inProfile,
 bool inCyclic,
 bool inSmooth,
 float inIndex,
 float& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inCyclic	bool			
→	inSmooth	bool			Determines whether an interpolation between two profile elements should be smooth
→	inIndex	float	-∞ -∞	0.0f	
←	outValue	float&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty profile on input in GetProfileElement_Interpolated.
DomainError	Index out of range in GetProfileElement_Interpolated.

GetProfileValue

Header: AVL.h
Namespace: avl
Module: FoundationPro

Gets a single value from a profile, located at the specified X (real-world) coordinate.

Syntax

```
void avl::GetProfileValue
(
 const avl::Profile& inProfile,
 float inX,
 bool inSmooth,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inX	float		X coordinate at which the profile value is calculated
→	inSmooth	bool		Determines whether an interpolation between two profile elements should be smooth
←	outValue	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty profile on input in GetProfileValue.
DomainError	X coordinate out of range in GetProfileValue.

ProfileCoordinates

Header: AVL.h
Namespace: avl
Module: FoundationPro

Returns an array of all X and Y coordinates of the input profile.

Syntax

```
void avl::ProfileCoordinates
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 atl::Array<float>& outXCoordinates,
 atl::Array<float>& outYCoordinates
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
←	outXCoordinates	Array<float>&		
←	outYCoordinates	Array<float>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileCoordinates.

ProfileIndices

Header: AVL.h
Namespace: avl
Module: FoundationPro

Returns an array of all indices of the input profile (0, 1, 2, ...).

Syntax

```
void avl::ProfileIndices
(
 const avl::Profile& inProfile,
 atl::Array<int>& outIndices
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
←	outIndices	Array<int>&		

SetProfileElement

Header: AVL.h
Namespace: avl
Module: FoundationPro

Sets a single element in a profile, located at the specified index.

Syntax

```
void avl::SetProfileElement
(
 avl::Profile& ioProfile,
 int inIndex,
 bool inInverse,
 float inValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioProfile	Profile&			
	inIndex	int	0 – ∞		
	inInverse	bool			Reversed order of elements
	inValue	float			

Errors

List of possible exceptions:

Error type	Description
DomainError	inIndex is out of profile range in SetProfileElement.

SetProfileXTransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Sets the offset and the scale of a profile in the X axis.

Applications: Makes it possible to use real-world X coordinates in a profile.

Syntax

```
void avl::SetProfileXTransform
(
 avl::Profile& ioProfile,
 float inXOffset,
 float inXScale
)
```

Parameters

	Name	Type	Range	Default	Description
	ioProfile	Profile&			
	inXOffset	float		0.0f	
	inXScale	float	0.001 – ∞	1.0f	

SkipEmptyProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

If the input profile contains at least one element, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty profiles, e.g. just before the ProfileAverage filter is to be invoked.

Syntax

```
void avl::SkipEmptyProfile
(
 const avl::Profile& inProfile,
 atl::Conditional<avl::Profile>& outNotEmptyProfile,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
←	outNotEmptyProfile	Conditional<Profile>&		
←	outIsNotEmpty	bool&		

51. Deep Learning

Table of content:

MergeCharactersIntoLines

Header: AVL.h
Namespace: avl
Module: DL_OCR

Converts a output of Deep Learning filter DL_ReadCharacters to lines of text.

Syntax

```
void avl::MergeCharactersIntoLines
(
 const atl::Array<avl::OcrResult>& inCharacters,
 float inMaxGap,
 float inMaxShift,
 float inMargin,
 int inMinLength,
 bool inFlatten,
 const avl::GrammarRulesPattern& inPattern,
 atl::Optional<const atl::Array<atl::Array<avl::OcrCandidate>>&> inCandidates,
 float inMinScore,
 avl::LineDirection::Type inLineDirection,
 atl::Array<avl::Rectangle2D>& outLines,
 atl::Array<atl::String>& outStrings,
 atl::Array<atl::Conditional<int>>& outMapping,
 atl::Array<float>& outScores,
 atl::Array<avl::OcrResult>& outProcessedCharacters
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCharacters	const Array<OcrResult>&			Output of DL_ReadCharacters
→	inMaxGap	float	0.0 – 10.0	0.25f	Maximum gap between adjacent characters along the reading direction, denoted as fraction of 'A' char height
→	inMaxShift	float	0.0 – 1.0	0.25f	Maximum misalignment between adjacent characters perpendicular to the reading direction, denoted as fraction of 'A' char height
→	inMargin	float	0.0 – 10.0		Additional margin added to result, denoted as fraction of 'A' char height
→	inMinLength	int	1 – 200	1	Minimal number of chars to create line
→	inFlatten	bool		False	If True, it concatenates the words on the line into a single result string, otherwise each word is a separate result string
→	inPattern	const GrammarRulesPattern&			Pattern used in Grammar rules filtering
→	inCandidates	Optional<const Array<Array<OcrCandidate>>&>		NIL	Candidates – optional output of DL_ReadCharacters, Required when using grammar rules (when inPattern is not empty)
→	inMinScore	float	0.0 – 1.0	0.2f	Minimum score for filtering the line of text
→	inLineDirection	LineDirection::Type		Horizontal	Expected text orientation direction
←	outLines	Array<Rectangle2D>&			Minimal Box which cover all selected character boxes
←	outStrings	Array<String>&			Text of merged characters
←	outMapping	Array<Conditional<int>>&			Mapping between input characters and output lines, outMapping[i] stores the index line to which inCharacters[i] belongs. If outMapping[i] is NIL it means that inCharacters[i] has not been added to any line
←	outScores	Array<float>&			Calculated the score for the line
←	outProcessedCharacters	Array<OcrResult>&			Contains the full set of character results after grammar rule processing. Maintains a one-to-one correspondence with inCharacters, preserving original positions but possibly with modified values, scores, or other attributes based on grammar rule application.

Description

This tool takes the text contained in OcrResultArray from the **DL_ReadCharacters** and merges it into lines.

Grammar Rules:

This feature can be used if we know the structure of the text we want to read. Define the **inPattern** string that you want to match against OCR results using regex syntax. This function uses more internal information **inCandidates** from Deep Learning filter **DL_ReadCharacters** to achieve the best matching to **inPattern**. Pattern is concatenation of pattern element.

Note: To use grammar rules the inputs: **inCharacters**, **inPattern**, **inCandidates** are required

Pattern elements can be:

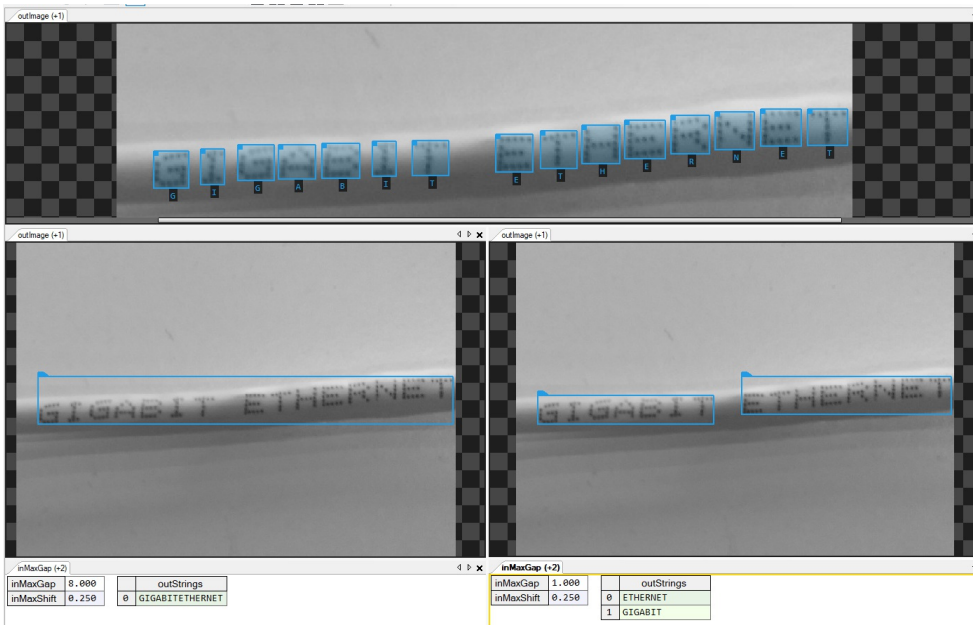
- **Individual character**: one of character supported in **DL_ReadCharacters**
  - Escaping operational characters: Use a backslash to treat operational characters as normal: \\, *, \?, \., \+, \-, \], \[, \), \(.
  - Whitespace Macro: \s represents a whitespace character (applicable only if **inFlatten** = True), space is also supported.
- **Character class** is a set of characters enclosed within square brackets []. It allows you to match any one character from the specified set. Example of usage:
  - List of characters: [abc] Matches any one of the characters a, b, or c.
  - Range: [a-z] Matches any one of the characters from a to z.
  - Mix of them: [a-zA-Z12] Matches any one of the characters from a to z, A to Z and 1,2.
  - Predefined character classes:
    - \d is equivalent to [0-9]
    - \w corresponds to [a-zA-Z0-9_]
    - . (dot) matches any single character (\w plus special characters)

    Note: Inside a character class, the following characters require escaping with a backslash \\, \-, \].
    Ex. [a.*|] is valid pattern which matches with the characters: a,.,*,|.
- **Chain** is an extended string created by concatenating individual characters and character classes. Instance:
  - abc – matches text abc
  - [Aa]bc – matches texts: abc and Abc
  - \dabc – matches texts: 0abc, 1abc, ..., 9abc
- **Alternative** is used to match one pattern or another. It's sequence of chains separated by pipe symbol | in round brackets (). Demonstration:
  - (abc|def) matches texts: abc and def
  - ([Aa]bc|\dabc) matches texts: abc, Abc, 0abc, 1abc, ..., 9abc

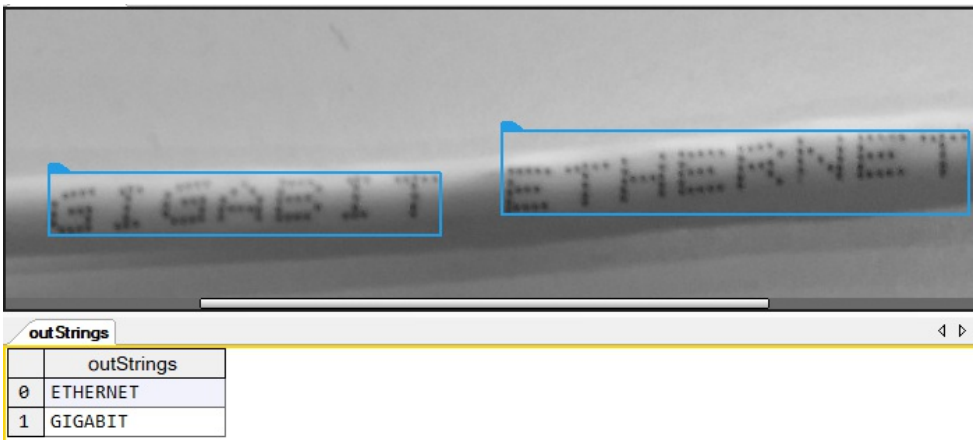
    Note: Round round brackets are required. Ex. ~~a|b~~
    Note: Nested brackets aren't supported. Ex. ~~(a|(b|c))~~
- **Special operators** can modify or repeat the preceding expression.
  - * (star): means zero or more occurrences of the preceding expression (in particular ".*" means any sequence), but tries to match as many characters as possible
  - + (plus): means one or more occurrences of the preceding element, maximizing the number of characters matched.
  - ? (question mark): means zero or one occurrence of the preceding element, with a preference for one.
  - *? (lazy star): means zero or more occurrences of the preceding expression, but tries to match as few characters as possible.
  - +? (lazy plus): means one or more occurrences, but minimizes the number of characters matched.

  Special operators can be added after the pattern element; Ex. [ABC]*, [0-9]?, (ABC|DEF)+
  Note: Special operators cannot be used inside alternative: Ex. ~~(a*|b)~~

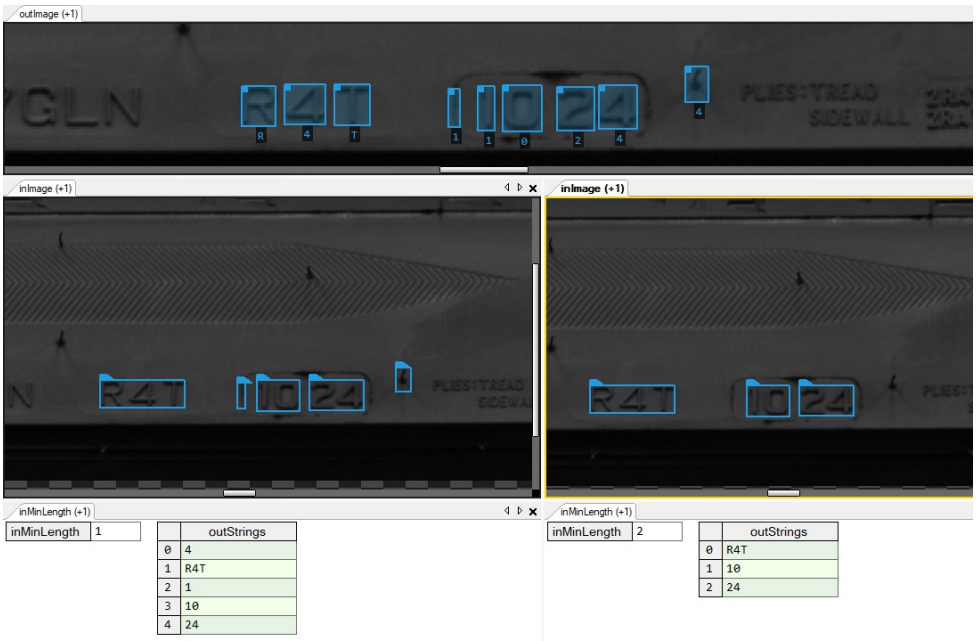
Depending on the inMaxGap and inMaxShift values, we can get different numbers of lines. See the image below, where increasing the inMaxGap results in one line of text, whereas a smaller value will return two separate lines:



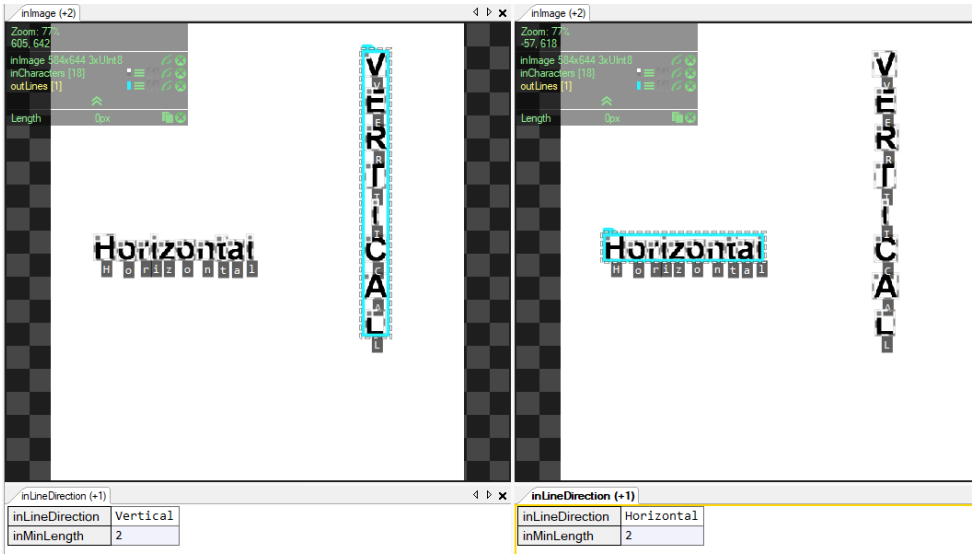
The lines are sorted by the Y value, e.g.:



The tool can also be used to get rid of false characters by setting a different value of the inMinLength parameter. In the image below, setting the inMinLength to 2 resulted in filtering out single false characters returned by the AvsFilter_DL_ReadCharacters tool.



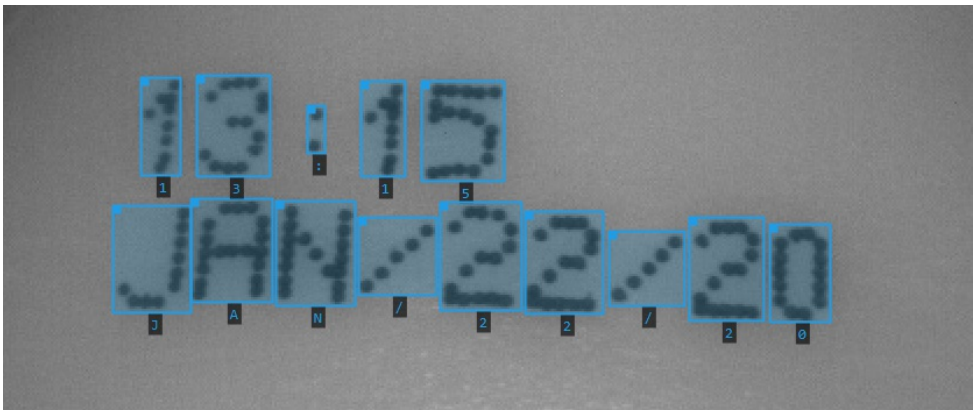
The **inLineDirection** parameter specifies the text orientation: Horizontal for left-to-right text, Vertical for top-to-bottom text. When set to Vertical, characters are grouped into columns instead of rows, and reading order follows the vertical axis.



Examples

Using of grammar rules:

1. To find date on this image:



inPattern= (JAN|FEB|MAR|APR|MAY|JUN|JUL|AUG|SEP|OCT|NOV|DEC)/\d\d/\d\d
outStrings= [JAN/22/20]

2. Finding website address:

inPattern= www\.[a-z]+\.com[a-z/]*
outStrings= [www.zebra.com/silverline]

3. To get serial number:

inPattern= Serial Number: \d+
outStrings=[Serial Number: 678000004455]

Remarks

This article concerns the functionalities related to another product: Deep Learning Add-on.

Errors

List of possible exceptions:

Error type	Description
DomainError	If you want to use grammar rules, please add inCandidates from filter DL_ReadCharacters.outCandidates and set True value on DL_ReadCharacters.inCalculateCandidates.
DomainError	inCandidates and inCharacters must have the same size.

MergeCharactersIntoOneLine

Header: AVL.h
Namespace: avl
Module: DL_OCR

Converts the output of the Deep Learning filter DL_ReadCharacters into a single text value, with the detected lines separated by a new line character.

Syntax

```
void avl::MergeCharactersIntoOneLine
(
 const atl::Array<avl::OcrResult>& inCharacters,
 float inMaxGap,
 float inMaxShift,
 float inMargin,
 int inMinLength,
 const avl::GrammarRulesPattern& inPattern,
 atl::Optional<const atl::Array<atl::Array<avl::OcrCandidate>>&> inCandidates,
 float inMinScore,
 avl::LineDirection::Type inLineDirection,
 atl::String& outText,
 avl::Rectangle2D& outLine,
 float& outScore,
 atl::Array<atl::Conditional<int>>& outMapping,
 atl::Array<avl::OcrResult>& outProcessedCharacters
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCharacters	const Array<OcrResult>&			Output of DL_ReadCharacters
→	inMaxGap	float	0.0 – 10.0	0.25f	Maximum gap between adjacent characters along the reading direction, denoted as fraction of 'A' char height
→	inMaxShift	float	0.0 – 1.0	0.25f	Maximum misalignment between adjacent characters perpendicular to the reading direction, denoted as fraction of 'A' char height
→	inMargin	float	0.0 – 10.0		Additional margin added to result, denoted as fraction of 'A' char height
→	inMinLength	int	1 – 200	1	Minimal number of chars to create line
→	inPattern	const GrammarRulesPattern&			Pattern used in Grammar rules filtering; a new line escape sequence is supported to match across detected lines
→	inCandidates	Optional<const Array<Array<OcrCandidate>>&>		NIL	Candidates – optional output of DL_ReadCharacters, Required when using grammar rules (when inPattern is not empty)
→	inMinScore	float	0.0 – 1.0	0.2f	Minimum score for filtering the line of text
→	inLineDirection	LineDirection::Type		Horizontal	Expected text orientation direction
←	outText	String&			All merged characters as a single text value, with the detected lines separated by a new line character
←	outLine	Rectangle2D&			Minimal box which covers all selected character boxes
←	outScore	float&			Calculated score for the whole result
←	outMapping	Array<Conditional<int>>&			Mapping between input characters and the output text, outMapping[i] is 0 if inCharacters[i] has been added to the result, NIL otherwise
←	outProcessedCharacters	Array<OcrResult>&			Contains the full set of character results after grammar rule processing. Maintains a one-to-one correspondence with inCharacters, preserving original positions but possibly with modified values, scores, or other attributes based on grammar rule application.

Description

This tool takes the text contained in OcrResultArray from the **DL_ReadCharacters** and merges it into a single text value returned in **outText**. Characters placed in the same line are joined with a space (exactly like **MergeCharactersIntoLines** with **inFlatten = True**), and the detected lines, stacked one above another, are joined with a new line character (\n). The whole result is therefore returned as one value together with a single bounding box **outLine** and a single **outScore**, instead of an array of lines.

Use **MergeCharactersIntoLines** when you need each line as a separate result; use this filter when the text should be read as one multi-line value.

Grammar Rules:

This feature can be used if we know the structure of the text we want to read. Define the **inPattern** string that you want to match against OCR results using regex syntax. This function uses more internal information **inCandidates** from Deep Learning filter **DL_ReadCharacters** to achieve the best matching to **inPattern**. Pattern is concatenation of pattern element. With this filter the grammar rules run once over the whole text, so a pattern may also span several lines (see the \n element below).

Note: To use grammar rules the inputs: **inCharacters**, **inPattern**, **inCandidates** are required

Pattern elements can be:

- **Individual character**: one of character supported in **DL_ReadCharacters**
  - Escaping operational characters: Use a backslash to treat operational characters as normal: \\, *, \?, \., \+, \-, \], \[, \), \(.
  - Whitespace Macro: \s represents a whitespace gap between words on the same line, space is also supported.
  - New line: \n matches a line break between two detected lines. Unlike \s (and space), which match a whitespace gap between words on the same line, \n matches only the transition to the next line, so a single pattern can span several lines. Example: \w+\n\d+ matches a word on one line directly followed by digits on the next line. Note: . (dot) does not match a line break.

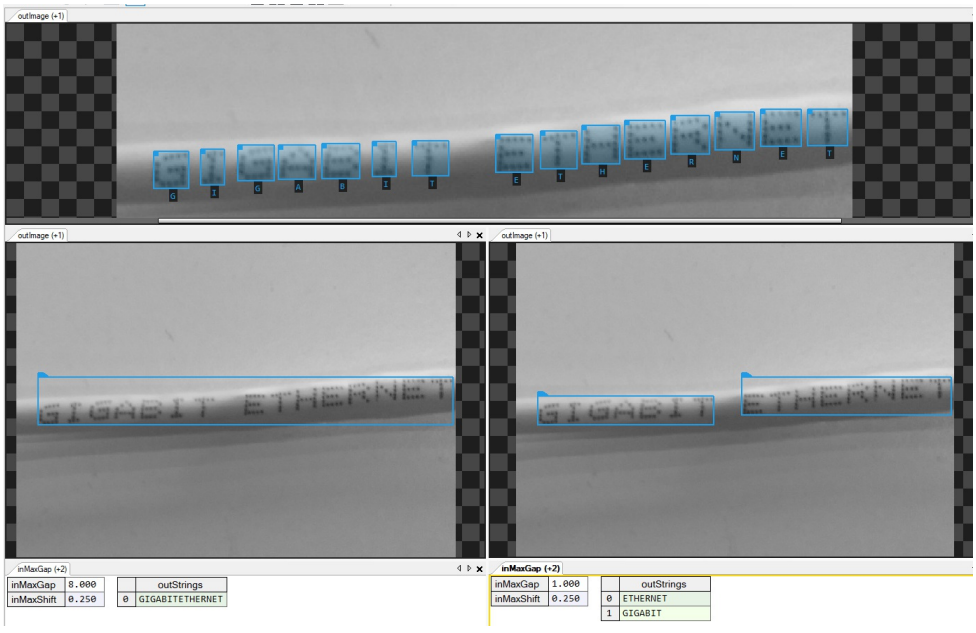
- **Character class** is a set of characters enclosed within square brackets []. It allows you to match any one character from the specified set. Example of usage:
  - List of characters: [abc] Matches any one of the characters a, b, or c.
  - Range: [a-z] Matches any one of the characters from a to z.
  - Mix of them: [a-zA-Z12] Matches any one of the characters from a to z, A to Z and 1,2.
  - Predefined character classes:
    - \d is equivalent to [0-9]
    - \w corresponds to [a-zA-Z0-9_]
    - . (dot) matches any single character on a line (\w plus special characters); it does not match a line break

  Note: Inside a character class, the following characters require escaping with a backslash \\, \-, \].
  Ex. [a.*|] is valid pattern which matches with the characters: a,.,*,|.
- **Chain** is an extended string created by concatenating individual characters and character classes. Instance:
  - abc – matches text abc
  - [Aa]bc – matches texts: abc and Abc
  - \dabc – matches texts: 0abc, 1abc, ..., 9abc
- **Alternative** is used to match one pattern or another. It's sequence of chains separated by pipe symbol | in round brackets (). Demonstration:
  - (abc|def) matches texts: abc and def
  - ([Aa]bc|\dabc) matches texts: abc, Abc, 0abc, 1abc, ..., 9abc

    Note: Round round brackets are required. Ex. ~~a|b~~
    Note: Nested brackets aren't supported. Ex. ~~(a|(b|c))~~
- **Special operators** can modify or repeat the preceding expression.
  - * (star): means zero or more occurrences of the preceding expression (in particular ".*" means any sequence), but tries to match as many characters as possible
  - + (plus): means one or more occurrences of the preceding element, maximizing the number of characters matched.
  - ? (question mark): means zero or one occurrence of the preceding element, with a preference for one.
  - *? (lazy star): means zero or more occurrences of the preceding expression, but tries to match as few characters as possible.
  - +? (lazy plus): means one or more occurrences, but minimizes the number of characters matched.

  Special operators can be added after the pattern element; Ex. [ABC]*, [0-9]?, (ABC|DEF)+
  Note: Special operators cannot be used inside alternative: Ex. ~~(a*|b)~~

Depending on the inMaxGap and inMaxShift values, characters are grouped into a different number of lines, which then end up separated by a new line character in **outText**. See the image below, where increasing the inMaxGap results in one line of text, whereas a smaller value will return two separate lines:

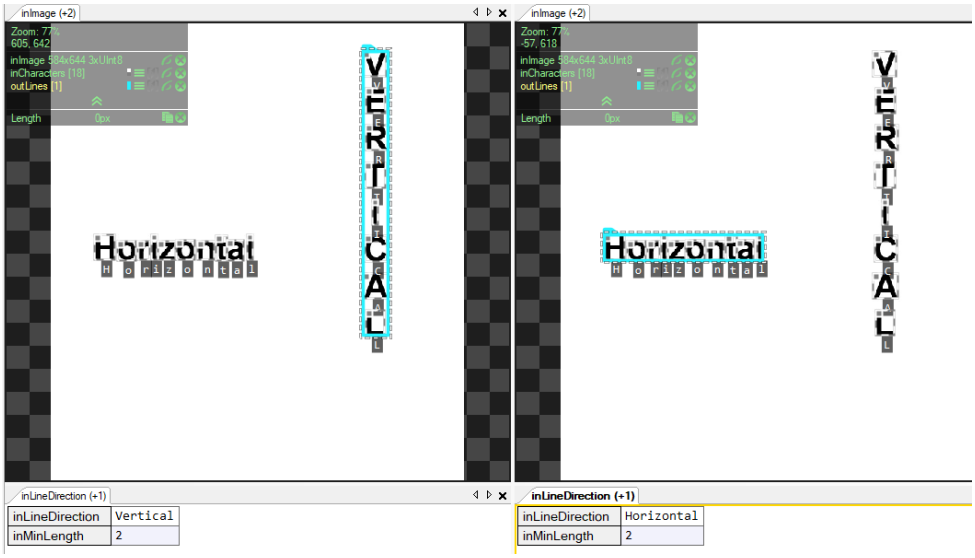


The lines are sorted by the Y value before being joined with a new line character.

The tool can also be used to get rid of false characters by setting a different value of the inMinLength parameter, which filters out short groups of characters returned by the AvsFilter_DL_ReadCharacters tool.

The **inLineDirection** parameter specifies the text orientation: Horizontal for left-to-right text, Vertical for top-to-bottom text. When set to Vertical, characters are grouped into columns instead of

rows, and reading order follows the vertical axis.



Examples

Assume **DL_ReadCharacters** returned the following two-line label:

PRD:2021/07/07 08:45
BEST BEF0RE:2024/07/07

1. Reading the whole label as a single value (empty **inPattern**). Characters on a line are joined with a space and the two lines with a new line character:

inPattern= (empty)
outText= PRD:2021/07/07 08:45\nBEST BEF0RE:2024/07/07

2. Matching across the line break with the \n element - the time at the end of the first line followed by the beginning of the second line:

inPattern= \d\d:\d\d\nBEST
outText= 08:45\nBEST

3. Matching a value that continues on the next line, e.g. a "best before" date split over two lines:

inPattern= BEF0RE:\d\d\d\d/\d\d/\d\d
outText= BEF0RE:2024/07/07

Remarks

This article concerns the functionalities related to another product: Deep Learning Add-on.

Errors

List of possible exceptions:

Error type	Description
DomainError	If you want to use grammar rules, please add inCandidates from filter DL_ReadCharacters.outCandidates and set True value on DL_ReadCharacters.inCalculateCandidates.
DomainError	inCandidates and inCharacters must have the same size.

ChargeImageMemoryPools

Header: AVL.h
Namespace: avl
Module: FoundationLite

Preallocates memory buffers for images.

Applications: This may improve performance when many images are created and destroyed in an application.

Syntax

```
void avl::ChargeImageMemoryPools
(
 const atl::Array<int>& inRequestedPoolSizes,
 bool inTouch
)
```

Parameters

	Name	Type	Default	Description
→	inRequestedPoolSizes	const Array<int>&		Copy a value from InspectImageMemoryPools.outPoolSizes
→	inTouch	bool		Forces getting the new memory pools to the cache memory

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect size of 'inRequestedPoolSizes' array.

Also in AVL Lite

CheckLicense

Header: AVL.h
Namespace: avl
Module: FoundationLite

Check license for a specified module.

Syntax

```
void avl::CheckLicense
(
 avl::ProductType::Type inProductType,
 bool& outIsValid
)
```

Parameters

	Name	Type	Default	Description
→	inProductType	ProductType::Type		
←	outIsValid	bool&		

ControlAVX2

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables or disables AVX2 cpu extension usage by other filters.

Syntax

```
void avl::ControlAVX2
(
 bool inIsEnabled,
 bool& outIsAvailable
)
```

Parameters

	Name	Type	Default	Description
→	inIsEnabled	bool	True	When 'true' AVX2 instructions are used
←	outIsAvailable	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

ControlImageMemoryPools

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables or disables deterministic image memory allocator.

Applications: This may improve performance when many images are created and destroyed in an application.

Syntax

```
void avl::ControlImageMemoryPools
(
 bool inIsEnabled
)
```

Parameters

	Name	Type	Default	Description
→	inIsEnabled	bool	True	Specifies whether memory pools should be used or not

ControlParallelComputing

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables or disables filters multithreading parallelization.

Syntax

```
void avl::ControlParallelComputing
(
 bool inIsEnabled,
 atl::Optional<int> inThreadCount,
 atl::Optional<int> inBlockTime,
 int& outThreadCount
)
```

Parameters

	Name	Type	Range	Default	Description
→	inIsEnabled	bool		True	When 'true' parallel computing is used.
→	inThreadCount	Optional<int>	1 - 128	NIL	Requested number of threads.
→	inBlockTime	Optional<int>		NIL	Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping.
←	outThreadCount	int&			Actually available number of threads.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported on this platform.

ControlSIMD

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables or disables SIMD cpu extension (e.g. SSE, AVX2, NEON) usage by other filters. This filter does not affect third party components e.g. camera software, OpenCV.

Syntax

```
void avl::ControlSIMD
(
 atl::Optional<avl::SimdLevel::Type> inLevel,
 avl::SimdLevel::Type& outLevel
)
```

Parameters

	Name	Type	Default	Description
→	inLevel	Optional<SimdLevel::Type>	NIL	Maximum simd level to be enabled
←	outLevel	SimdLevel::Type&		Actually adjusted simd level

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ControlSSE

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enables or disables SSE cpu extension usage by other filters.

Syntax

```
void avl::ControlSSE
(
 bool inIsEnabled,
 bool& outIsAvailable
)
```

Parameters

	Name	Type	Default	Description
→	inIsEnabled	bool	True	When 'true' SSE instructions are used
←	outIsAvailable	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

DischargeImageMemoryPools

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Releases preallocated image memory buffers.

Syntax

```
void avl::DischargeImageMemoryPools()
```

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

GetAvailableLicenses

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reads available licenses in the system.

Syntax

```
void avl::GetAvailableLicenses
(
 atl::Array<avl::License>& outLicenses
)
```

Parameters

	Name	Type	Default	Description
←	outLicenses	Array<License>&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

GetComputerID

Header: AVL.h
Namespace: avl
Module: FoundationLite

Gets current Computer ID.

Applications: Can be used for creating custom license protection for integrator's applications.

Syntax

```
void avl::GetComputerID
(
 atl::String& outComputerID
)
```

Parameters

	Name	Type	Default	Description
⬅	outComputerID	String&		

GetDongleSerialNumber

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Gets the current usb dongle's serial number.

Syntax

```
void avl::GetDongleSerialNumber
(
 atl::String& outDongleSerialNumber
)
```

Parameters

	Name	Type	Default	Description
⬅	outDongleSerialNumber	String&		

GetLibraryVersion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Gets current library version.

Syntax

```
void avl::GetLibraryVersion
(
 int& outMajor,
 int& outMinor,
 int& outBuild,
 int& outRevision
)
```

Parameters

	Name	Type	Default	Description
⬅	outMajor	int&		
⬅	outMinor	int&		
⬅	outBuild	int&		
⬅	outRevision	int&		

Also in AVL Lite

GetThreadLimitInfo

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns how many threads are possible and a list of threads currently being used.

Applications: Makes it easier to diagnose licensing problems related to exceeding the limit of threads.

Syntax

```
void avl::GetThreadLimitInfo
(
 atl::Conditional<int>& outThreadLimit,
 atl::Array<atl::String>& outActiveThreadIds
)
```

Parameters

	Name	Type	Default	Description
⬅	outThreadLimit	Conditional<int>&		
⬅	outActiveThreadIds	Array<String>&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

InitLibrary

Header: AVL.h
Namespace: avl
Module: FoundationLite

Initializes library internals. Should be called before any other function from AVL.

Applications: If you do not call this first, initialization will be done in the first iteration, possibly affecting system's performance.

Syntax

```
void avl::InitLibrary()
```

Also in AVL Lite

InspectImageMemoryPools

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns information about allocated image memory buffers. This information can be used for preallocation.

Syntax

```
void avl::InspectImageMemoryPools
(
 bool& outIsEnabled,
 atl::Array<int>& outPoolSizes,
 atl::Array<int>& outBlockLengths,
 int& outTotalUsage
)
```

Parameters

	Name	Type	Default	Description
⬅	outIsEnabled	bool&		Specifies whether memory pools are used or not
⬅	outPoolSizes	Array<int>&		Count of blocks in consecutive pools
⬅	outBlockLengths	Array<int>&		Length of blocks in consecutive pools
⬅	outTotalUsage	int&		Total image memory allocated [B]

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VerifyProjectID

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Verifies a project ID.

Applications: This tools is useful for system integrators who need verification if a system is used with a license coming from a legitimate source.

Syntax

```
void avl::VerifyProjectID
(
 int inProjectID,
 bool inThrowError,
 bool& outIsLicenseValid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProjectID	int	0 – ∞		Project ID assigned to your license
→	inThrowError	bool			
←	outIsLicenseValid	bool&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

WriteLog

Header: AVL.h
Namespace: avl
Module: FoundationLite

Write log message with selected log level.

Syntax

```
void avl::WriteLog
(
 const atl::String& inMessage,
 const avl::LogsLevel::Type& inLogLevel
)
```

Parameters

	Name	Type	Default	Description
→	inMessage	const String&		
→	inLogLevel	const LogsLevel::Type&

CreateCircleFittingMap3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Precomputes a data object that is required for fast circle fitting on surfaces.

Applications: Used together with circle fitting, but can be moved before the loop.

Syntax

```
void avl::CreateCircleFittingMap3D
(
 const avl::SurfaceFormat& inSurfaceFormat,
 const avl::CircleFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 const int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 avl::CircleFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceFormat	const SurfaceFormat&			Dimensions, depth image pixel type, coordinate offsets and scales of a surface on which circle fitting will be performed
→	inFittingField	const CircleFittingField&			Defines a ring in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	const int	3 – ∞	10	The number of points that will be searched to estimate the position of the circle
→	inSamplingStep	Optional<float>		NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	The width of each scan field in pixels of the surface depth image
→	inSurfaceInterpolation	InterpolationMethod::Type		InterpolationMethod::NearestNeighbour	Interpolation method used for extraction of depth image pixel values
←	outFittingMap	CircleFittingMap&			Optimized data required for circle fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

CreatePathFittingMap3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Precomputes a data object that is required for fast path fitting on surfaces.

Applications: Used together with path fitting, but can be moved before the loop.

Syntax

```
void avl::CreatePathFittingMap3D
(
 const avl::SurfaceFormat& inSurfaceFormat,
 const avl::PathFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 atl::Optional<float> inScanStep,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 avl::PathFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceFormat	const SurfaceFormat&			Dimensions, depth image pixel type, coordinate offsets and scales of a surface on which path fitting will be performed
→	inFittingField	const PathFittingField&			Defines a stripe in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanStep	Optional<float>	0.0 – ∞	NIL	Optional implicit conversion of the input path to an equidistant one
→	inSamplingStep	Optional<float>		NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	The width of each scan field in pixels of the surface depth image
→	inSurfaceInterpolation	InterpolationMethod::Type		InterpolationMethod::NearestNeighbour	Interpolation method used for extraction of depth image pixel values
←	outFittingMap	PathFittingMap&			Optimized data required for path fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

CreateSegmentFittingMap3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Precomputes a data object that is required for fast segment fitting on surfaces.

Applications: Used together with segment fitting, but can be moved before the loop.

Syntax

```
void avl::CreateSegmentFittingMap3D
(
 const avl::SurfaceFormat& inSurfaceFormat,
 const avl::SegmentFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 const int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 avl::SegmentFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceFormat	const SurfaceFormat&			Dimensions, depth image pixel type, coordinate offsets and scales of a surface on which segment fitting will be performed
→	inFittingField	const SegmentFittingField&			Defines a rectangle in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	const int	3 – ∞	10	The number of points that will be searched to estimate the position of the segment
→	inSamplingStep	Optional<float>		NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	The width of each scan field in pixels of the surface depth image
→	inSurfaceInterpolation	InterpolationMethod::Type		InterpolationMethod::NearestNeighbour	Interpolation method used for extraction of depth image pixel values
←	outFittingMap	SegmentFittingMap&			Optimized data required for segment fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

CreateSurfaceMeasurementMap

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

(Pre)computes surface sampling locations used by MeasureObjectWidth3D function.

Syntax

```
void avl::CreateSurfaceMeasurementMap
(
 const avl::SurfaceFormat& inSurfaceFormat,
 const avl::SegmentScanField& inScanField,
 atl::Optional<const avl::CoordinateSystem2D&> inScanFieldAlignment,
 int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 atl::Array<avl::ScanMap>& outMeasurementMap,
 atl::Optional<avl::SegmentScanField&> outAlignedScanField = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceFormat	const SurfaceFormat&			Information about dimensions, depth and pixel type of the surface
→	inScanField	const SegmentScanField&			Field in which scans will be performed
→	inScanFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan field to the position of the inspected object
→	inScanCount	int	2 – ∞	5	Number of scans to be performed
→	inSamplingStep	Optional<float>		NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	Width of the scan area
→	inSurfaceInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used in extraction of image pixel values
←	outMeasurementMap	Array<ScanMap>&			
←	outAlignedScanField	Optional<SegmentScanField&>		NIL	Field in which the scans will be performed
🔍	diagScanSegments	Array<Segment2D>&			Array of scan segments

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanField**.

Read more about Optional Outputs.

FitCircleToEdges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D edge detections and finds a circle that best matches the detected points.

Applications: Precise detection of a circular object or hole, whose rough location is known beforehand.

Syntax

```
void avl::FitCircleToEdges3D
(
 const avl::Surface& inSurface,
 const CircleFittingMap& inFittingMap,
 const EdgeScanParams3D& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 float inMaxIncompleteness,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle,
 atl::Optional<atl::Array<atl::Conditional<avl::SurfaceEdge1D>>&> outEdges = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Surface to fit the circle to
→	inFittingMap	const CircleFittingMap&			Input fitting map
→	inEdgeScanParams	const EdgeScanParams3D&			Parameters controlling the edge extraction process
→	inEdgeSelection	Selection::Type		SelectionBest	Selection mode of edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of edge points not found
→	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit a circle
→	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
←	outCircle	Conditional<Circle3D>&			Fitted circle or nothing if the fitting fails
←	outEdges	Optional<Array<Conditional<SurfaceEdge1D>>&>		NIL	Found edges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual circle points and the corresponding reference circle points
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the fitting Circle
←	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outInliers**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

FitCircleToEdges3D_Direct

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D edge detections in 3D and finds a circle that best matches the detected points.

Applications: Precise detection of a circular object or hole, whose rough location is known beforehand.

Syntax

```
void avl::FitCircleToEdges3D_Direct
(
 const avl::Surface& inSurface,
 const avl::CircleFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 const avl::InterpolationMethod::Type inSurfaceInterpolation,
 const avl::EdgeScanParams3D& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 float inMaxIncompleteness,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle,
 atl::Optional<atl::Array<atl::Conditional<avl::SurfaceEdge1D>>&> outEdges = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<avl::CircleFittingField&> outAlignedFittingField = atl::NIL,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			Surface to fit the circle to
➡	inFittingField	const CircleFittingField&			Circle fitting field
➡	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
➡	inScanCount	int	3 – ∞	10	The number of points that will be searched to estimate the position of the circle
➡	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
➡	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
➡	inSurfaceInterpolation	const InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
➡	inEdgeScanParams	const EdgeScanParams3D&		EdgeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 1.0f MinMagnitude: 5.0f EdgeTransition: LowToHigh)	Parameters controlling the edge extraction process
➡	inEdgeSelection	Selection::Type			Selection mode of edges
➡	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
➡	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
➡	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of edge points not found
➡	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit a circle
➡	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
⬅	outCircle	Conditional<Circle3D>&			Fitted circle or nothing if the fitting fails
⬅	outEdges	Optional<Array<Conditional<SurfaceEdge1D>>&>		NIL	Found edges
⬅	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual circle points and the corresponding reference circle points
⬅	outAlignedFittingField	Optional<CircleFittingField&>		NIL	Fitting field used; in the image coordinate system
⬅	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the fitting Circle
⬅	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
⬅	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outAlignedFittingField**, **outInliers**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Sampling step set to zero in FitCircleToEdges3D.

FitCircleToRidges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D ridge detections and finds a circle that best matches the detected points.

Applications: Precise detection of a circular object or hole, whose rough location is known beforehand.

Syntax

```
void avl::FitCircleToRidges3D
(
 const avl::Surface& inSurface,
 const CircleFittingMap& inFittingMap,
 const RidgeScanParams3D& inRidgeScanParams,
 avl::Selection::Type inRidgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 float inMaxIncompleteness,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle,

 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Surface to fit the circle to
→	inFittingMap	const CircleFittingMap&			Input fitting map
→	inRidgeScanParams	const RidgeScanParams3D&			Parameters controlling the ridge extraction process
→	inRidgeSelection	Selection::Type		SelectionBest	Selection mode of ridges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of ridge points not found
→	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit a circle
→	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
←	outCircle	Conditional<Circle3D>&			Fitted circle or nothing if the fitting fails
←	outRidges	Optional<Array<Conditional<SurfaceRidge1D>>&>		NIL	Found ridges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual circle points and the corresponding reference circle points
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the fitting Circle
←	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the ridge operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRidges**, **outDeviationProfile**, **outInliers**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Ridge operator parameters are too low in surface ridges detector in FitCircleToRidges3D.

FitCircleToRidges3D_Direct

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D ridge detections in 3D and finds a circle that best matches the detected points.

Applications: Precise detection of a circular object or hole, whose rough location is known beforehand.

Syntax

```
void avl::FitCircleToRidges3D_Direct
(
 const avl::Surface& inSurface,
 const avl::CircleFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 const avl::InterpolationMethod::Type inSurfaceInterpolation,
 const avl::RidgeScanParams3D& inRidgeScanParams,
 avl::Selection::Type inRidgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 float inMaxIncompleteness,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle,

 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			Surface to fit the circle to
➡	inFittingField	const CircleFittingField&			Circle fitting field
➡	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
➡	inScanCount	int	3 – ∞	10	The number of points that will be searched to estimate the position of the circle
➡	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
➡	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
➡	inSurfaceInterpolation	const InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
➡	inRidgeScanParams	const RidgeScanParams3D&		RidgeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f RidgeWidth: 5.0f RidgeMargin: 2.0f RidgeOperator: Minimum MinMagnitude: 5.0f RidgePolarity: Low)	Parameters controlling the ridge extraction process
➡	inRidgeSelection	Selection::Type			Selection mode of ridges
➡	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
➡	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
➡	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of ridge points not found
➡	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit a circle
➡	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
⬅	outCircle	Conditional<Circle3D>&			Fitted circle or nothing if the fitting fails
⬅	outRidges	Optional<Array<Conditional<SurfaceRidge1D>>&>		NIL	Found ridges
⬅	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual circle points and the corresponding reference circle points
⬅	outAlignedFittingField	Optional<CircleFittingField&>		NIL	Fitting field used; in the image coordinate system
⬅	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the fitting Circle
⬅	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
⬅	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the ridge operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRidges**, **outDeviationProfile**, **outAlignedFittingField**, **outInliers**, **outHeightProfiles**, **outResponseProfiles**.

)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			Surface to fit the path to
➡	inFittingField	const PathFittingField&			Path fitting field
➡	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
➡	inScanStep	Optional<float>	0.0 – ∞	5.0f	Optional implicit conversion of the input path to an equidistant one
➡	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
➡	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
➡	inSurfaceInterpolation	const InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
➡	inRidgeScanParams	const RidgeScanParams3D&		RidgeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f RidgeWidth: 5.0f RidgeMargin: 2.0f RidgeOperator: Minimum MinMagnitude: 5.0f RidgePolarity: Low)	Parameters controlling the ridge extraction process
➡	inRidgeSelection	Selection::Type			Selection mode of ridges

	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
	inMaxPathInterpolationLength	Optional<int>	0 – ∞	1	Maximal number of consecutive points not found
	inMaxDeviationDelta	Optional<float>	0.0 – ∞	NIL	Maximal difference between deviations of consecutive path points
	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of ridge points not found
	outPath	Conditional<Array<Point3D> >&			Fitted path or nothing if the fitting failed
	outRidges	Optional<Array<Conditional<SurfaceRidge1D>>&>		NIL	Found ridges
	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual path points and the corresponding reference path points
	outAlignedFittingField	Optional<PathFittingField&>		NIL	Fitting field used; in the image coordinate system
	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the ridge operator response
	outPathSegments	Optional<Conditional<Array<Segment3D> >&>		NIL	Segments of the fitted path or nothing if the fitting failed
	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRidges**, **outDeviationProfile**, **outAlignedFittingField**, **outHeightProfiles**, **outResponseProfiles**, **outPathSegments**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Ridge operator parameters are too low in surface ridges detector in FitPathToRidges3D.
DomainError	Sampling step set to zero in FitPathToRidges3D.

FitPathToStripe3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D stripe detections and creates a path from the detected points.

Applications: Tracing of a stripe, whose rough location and shape is known beforehand.

Syntax

```
void avl::FitPathToStripe3D
(
 const avl::Surface& inSurface,
 const avl::PathFittingMap& inFittingMap,
 const StripeScanParams3D& inStripeScanParams,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Optional<int> inMaxPathInterpolationLength,
 atl::Optional<float> inMaxDeviationDelta,
 float inMaxIncompleteness,
 atl::Conditional<atl::Array<avl::Point3D> >& outPath,
 atl::Conditional<atl::Array<avl::Point3D> >& outLeftPath,
 atl::Conditional<atl::Array<avl::Point3D> >& outRightPath,
 atl::Optional<atl::Array<atl::Conditional<avl::SurfaceStripe1D> >&> outStripes = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL,
 atl::Optional<atl::Conditional<atl::Array<avl::Segment3D>>&> outPathSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Surface to fit the path to
→	inFittingMap	const PathFittingMap&			Input fitting map
→	inStripeScanParams	const StripeScanParams3D&			Parameters controlling the stripe extraction process
→	inStripeSelection	Selection::Type		Selection::Best	Selection mode of stripe
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
→	inMaxPathInterpolationLength	Optional<int>		NIL	Maximal number of consecutive points not found
→	inMaxDeviationDelta	Optional<float>	0.0 – ∞	NIL	Maximal difference between deviations of consecutive path points
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of stripe points not found
←	outPath	Conditional<Array<Point3D> >&			Fitted path or nothing if the fitting failed
←	outLeftPath	Conditional<Array<Point3D> >&			Fitted left path
←	outRightPath	Conditional<Array<Point3D> >&			Fitted right path
←	outStripes	Optional<Array<Conditional<SurfaceStripe1D> >&>		NIL	Found stripes
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual path points and the corresponding reference path points
←	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
←	outPathSegments	Optional<Conditional<Array<Segment3D>>&>		NIL	Segments of the fitted path or nothing if the fitting failed

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outDeviationProfile**, **outHeightProfiles**, **outResponseProfiles**, **outPathSegments**.

←	outStripes	Optional<Array<Conditional<SurfaceStripe1D>>&>		NIL	Found stripes
←	outStripePoints	Optional<Array<Point3D>&>		NIL	Extracted points of middle segment of a surface stripe
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual segment points and the corresponding reference segment points
←	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outStripePoints**, **outDeviationProfile**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

FitSegmentToStripe3D_Direct

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Performs a series of 1D edge detections in 3D and finds a segment that best matches the detected points.

Applications: Precise detection of a straight edge, whose rough location is known beforehand.

Syntax

```
void avl::FitSegmentToStripe3D_Direct
(
 const avl::Surface& inSurface,
 const avl::SegmentFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 int inScanCount,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 const avl::InterpolationMethod::Type inSurfaceInterpolation,
 const avl::StripeScanParams3D& inStripeScanParams,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 float inMaxIncompleteness,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Segment3D>& outSegment,
 atl::Conditional<avl::Segment3D>& outLeftSegment,
 atl::Conditional<avl::Segment3D>& outRightSegment,
 atl::Optional<atl::Array<atl::Conditional<avl::SurfaceStripe1D>>&> outStripes = atl::NIL,
 atl::Optional<atl::Array<avl::Point3D>&> outStripePoints = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<avl::SegmentFittingField&> outAlignedFittingField = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
	inSurface	const Surface&			Surface to fit segment to
	inFittingField	const SegmentFittingField&			Segment fitting field
	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
	inScanCount	int	3 – ∞	10	The number of points that will be searched to estimate the position of the segment
	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Desired distance between consecutive sampling points on the scan segments; if Nil, the bigger of surface X and Y scales is chosen
	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
	inSurfaceInterpolation	const InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
	inStripeScanParams	const StripeScanParams3D&		StripeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 1.0f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil MinStripeWidth: 0.0f MaxStripeWidth: Nil StripePolarity: High)	Parameters controlling the stripe extraction process
	inStripeSelection	Selection::Type			Selection mode of stripe
	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of stripe points not found
	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points

⬅	outSegment	Conditional<Segment3D>&		Fitted segment or nothing if the fitting fails
⬅	outLeftSegment	Conditional<Segment3D>&		Fitted left segment
⬅	outRightSegment	Conditional<Segment3D>&		Fitted right segment
⬅	outStripes	Optional<Array<Conditional<SurfaceStripe1D>>&>	NIL	Found stripes
⬅	outStripePoints	Optional<Array<Point3D>&>	NIL	Extracted points of middle segment of a surface stripe
⬅	outDeviationProfile	Optional<Conditional<Profile>&>	NIL	Profile of distances between the actual segment points and the corresponding reference segment points
⬅	outAlignedFittingField	Optional<SegmentFittingField&>	NIL	Fitting field used; in the image coordinate system
⬅	outHeightProfiles	Optional<Array<Profile>&>	NIL	Extracted surface height profiles
⬅	outResponseProfiles	Optional<Array<Profile>&>	NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&		Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&		Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outStripePoints**, **outDeviationProfile**, **outAlignedFittingField**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Sampling step set to zero in FitSegmentToStripe3D.

MeasureObjectWidth3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Measures the width of an object using stripe detection.

Applications: Easy and precise measurement of distances between to straight parallel edges.

Syntax

```
void avl::MeasureObjectWidth3D
(
 const avl::Surface& inSurface,
 const atl::Array<avl::ScanMap>& inMeasurementMap,
 const avl::StripeScanParams3D& inStripeScanParams,
 avl::MeasureObjectMethod::Type inMeasureMethod,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 int inOutlierCount,
 atl::Conditional<float>& outObjectWidth,
 atl::Conditional<avl::Segment2D>& outSegment1,
 atl::Conditional<avl::Segment2D>& outSegment2,
 atl::Optional<atl::Array<atl::Conditional<avl::SurfaceStripe1D>>&> outStripes = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outHeightProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inMeasurementMap	const Array<ScanMap>&			Input measurement map
→	inStripeScanParams	const StripeScanParams3D&			Parameters controlling the object stripe extraction process
→	inMeasureMethod	MeasureObjectMethod::Type			Method used to measure the object
→	inStripeSelection	Selection::Type		Selection::Best	Selection mode of edges of the object
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
→	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
→	inOutlierCount	int	0 – ∞		Determines how many outlying points are rejected before the width is measured
←	outObjectWidth	Conditional<float>&			Width of the object
←	outSegment1	Conditional<Segment2D>&			First edge of the object
←	outSegment2	Conditional<Segment2D>&			Second edge of the object
←	outStripes	Optional<Array<Conditional<SurfaceStripe1D>>&>		NIL	Detected stripes
←	outHeightProfiles	Optional<Array<Profile>&>		NIL	Extracted surface height profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outHeightProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid MeasurementMap in MeasureObjectWidth3D function. Use CreateSurfaceMeasurementMap function to create it properly.

BayerToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a Bayer-encoded color image into RGB color space.

Applications: Use this filter only if the conversion functionality is not provided by the camera (check appropriate pixel types).

Syntax

```
void avl::BayerToRgb
(
 const avl::Image& inMonoImage,
 avl::DebayeringMethod::Type inDebayeringMethod,
 avl::BayerType::Type inBayerType,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inMonoImage	const Image&		
→	inDebayeringMethod	DebayeringMethod::Type		
→	inBayerType	BayerType::Type		
←	outRgbImage	Image&		

Requirements

For input **inMonoImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSSE3 technology for pixels of types: UINT8(for inDebayeringMethod=Bilinear).

This operation is optimized for NEON technology for pixels of types: UINT8(for inDebayeringMethod=Bilinear).

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 1-channel image at input of BayerToRgb.
DomainError	Unsupported inBayerAlgorithm in BayerToRgb.
DomainError	Not supported inMonoImage pixel format in BayerToRgb. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

CmykToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Cyan-Magenta-Yellow-Key into Red-Green-Blue.

Applications: CMYK color space is designed for printing - not recommended for machine vision.

Syntax

```
void avl::CmykToRgb
(
 const avl::Image& inCmykImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inCmykImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inCmykImage** only pixel formats are supported: 4×uint8, 4×int8, 4×uint16, 4×int16, 4×int32, 4×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 4-channel image in CmykToRgb.
DomainError	Not supported inCmykImage pixel format in CmykToRgb. Supported formats: 4xUInt8, 4xInt8, 4xUInt16, 4xInt16, 4xInt32, 4xReal.

HsiToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Hue-Saturation-Intensity into Red-Green-Blue.

Syntax

```
void avl::HsiToRgb
(
 const avl::Image& inHsiImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inHsiImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inHsiImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in HsiToRgb.
DomainError	Not supported inHsiImage pixel format in HsiToRgb. Supported formats: 3xUInt8.

HslToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Hue-Saturation-Luminance to Red-Green-Blue.

Syntax

```
void avl::HslToRgb
(
 const avl::Image& inHslImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inHslImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inHslImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in HslToRgb.
DomainError	Not supported inHslImage pixel format in HslToRgb. Supported formats: 3xUInt8.

HsvToRgb

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts color space from Hue-Saturation-Value to Red-Green-Blue.

Syntax

```
void avl::HsvToRgb
(
 const avl::Image& inHsvImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inHsvImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inHsvImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in HsvToRgb.
DomainError	Not supported inHsvImage pixel format in HsvToRgb. Supported formats: 3xUInt8.

LabToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from L*a*b* to Red-Green-Blue.

Syntax

```
void avl::LabToRgb
(
 const avl::Image& inLabImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inLabImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inLabImage** only pixel formats are supported: 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in LabToRgb.
DomainError	Not supported inLabImage pixel format in LabToRgb. Supported formats: 3xReal.

Rgb555ToRgb888

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a RGB555 image into a RGB888 one.

Applications: Decompression of pixel depth from 2 to 3 bytes.

Syntax

```
void avl::Rgb555ToRgb888
(
 const avl::Image& inRgb555Image,
 avl::Image& outRgb888Image
)
```

Parameters

	Name	Type	Default	Description
→	inRgb555Image	const Image&		
←	outRgb888Image	Image&		

Requirements

For input **inRgb555Image** only pixel formats are supported: 1×uint16.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 1-channel and 16-bit image in Rgb555ToRgb888.
DomainError	Not supported inRgb555Image pixel format in Rgb555ToRgb888. Supported formats: 1xUInt16.

Rgb565ToRgb888

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a RGB565 image into a RGB888 one.

Applications: Decompression of pixel depth from 2 to 3 bytes.

Syntax

```
void avl::Rgb565ToRgb888
(
 const avl::Image& inRgb565Image,
 avl::Image& outRgb888Image
)
```

Parameters

	Name	Type	Default	Description
→	inRgb565Image	const Image&		
←	outRgb888Image	Image&		

Requirements

For input **inRgb565Image** only pixel formats are supported: 1×uint16.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 1-channel and 16-bit image in Rgb565ToRgb888.
DomainError	Not supported inRgb565Image pixel format in Rgb565ToRgb888. Supported formats: 1xUInt16.

Rgb888ToRgb555

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a RGB888 image into a RGB555 one.

Applications: Compression of pixel depth from 3 to 2 bytes.

Syntax

```
void avl::Rgb888ToRgb555
(
 const avl::Image& inRgb888Image,
 avl::Image& outRgb555Image
)
```

Parameters

	Name	Type	Default	Description
→	inRgb888Image	const Image&		
←	outRgb555Image	Image&		

Requirements

For input **inRgb888Image** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in Rgb888ToRgb555.
DomainError	Not supported inRgb888Image pixel format in Rgb888ToRgb555. Supported formats: 3xUInt8.

Rgb888ToRgb565

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a RGB888 image into a RGB565 one.

Applications: Compression of pixel depth from 3 to 2 bytes.

Syntax

```
void avl::Rgb888ToRgb565
(
 const avl::Image& inRgb888Image,
 avl::Image& outRgb565Image
)
```

Parameters

	Name	Type	Default	Description
→	inRgb888Image	const Image&		
←	outRgb565Image	Image&		

Requirements

For input **inRgb888Image** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in Rgb888ToRgb565.
DomainError	Not supported inRgb888Image pixel format in Rgb888ToRgb565. Supported formats: 3xUInt8.

RgbToBayer

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a RGB color image into Bayer-encoded color image.

Syntax

```
void avl::RgbToBayer
(
 const avl::Image& inRgbImage,
 avl::BayerType::Type inBayerType,
 avl::Image& outBayerImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
→	inBayerType	BayerType::Type		
←	outBayerImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image at input of RgbToBayer.
DomainError	Not supported bayer type value in RgbToBayer.
DomainError	Not supported inRgbImage pixel format in RgbToBayer. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToCmyk

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue into Cyan-Magenta-Yellow-Key.

Applications: CMYK color space is designed for printing - not recommended for machine vision.

Syntax

```
void avl::RgbToCmyk
(
 const avl::Image& inRgbImage,
 avl::Image& outCmykImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outCmykImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in RgbToCmyk.
DomainError	Not supported inRgbImage pixel format in RgbToCmyk. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToHsi

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue into Hue-Saturation-Intensity.

Applications: Color analysis is easier in the HSI color space than in RGB.

Syntax

```
void avl::RgbToHsi
(
 const avl::Image& inRgbImage,
 avl::Image& outHsiImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outHsiImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in RgbToHsi.
DomainError	Not supported inRgbImage pixel format in RgbToHsi. Supported formats: 3xUInt8.

RgbToHsl

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue to Hue-Saturation-Luminance.

Applications: Color analysis is easier in the HSL color space than in RGB.

Syntax

```
void avl::RgbToHsl
(
 const avl::Image& inRgbImage,
 avl::Image& outHslImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outHslImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in RgbToHsl.
DomainError	Not supported inRgbImage pixel format in RgbToHsl. Supported formats: 3xUInt8.

RgbToHsv

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts color space from Red-Green-Blue to Hue-Saturation-Value.

Applications: Color analysis is easier in the HSV color space than in RGB.

Syntax

```
void avl::RgbToHsv
(
 const avl::Image& inRgbImage,
 avl::Image& outHsvImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outHsvImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for SSE4 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in RgbToHsv.
DomainError	Not supported inRgbImage pixel format in RgbToHsv. Supported formats: 3xUInt8.

RgbToLab

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue to L*a*b*.

Syntax

```
void avl::RgbToLab
(
 const avl::Image& inRgbImage,
 avl::Image& outLabImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outLabImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in RgbToLab.
DomainError	Not supported inRgbImage pixel format in RgbToLab. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToXyz

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue to XYZ.

Applications: XYZ color space is designed for human perception - not recommended for machine vision.

Syntax

```
void avl::RgbToXyz
(
 const avl::Image& inRgbImage,
 avl::Image& outXyzImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outXyzImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when pixel type is uint8).

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in RgbToXyz.
DomainError	Not supported inRgbImage pixel format in RgbToXyz. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToYCoCg

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue into pseudointensitY-Orange-Green.

Syntax

```
void avl::RgbToYCoCg
(
 const avl::Image& inRgbImage,
 avl::Image& outYCoCgImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outYCoCgImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in RgbToYCoCg.
DomainError	Not supported inRgbImage pixel format in RgbToYCoCg. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToYCoCgR

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue into pseudointensitY-Orange-Green-with-Reversibility.

Syntax

```
void avl::RgbToYCoCgR
(
 const avl::Image& inRgbImage,
 avl::Image& outYCoCgRImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outYCoCgRImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in RgbToYCoCgR.
DomainError	Not supported inRgbImage pixel format in RgbToYCoCgR. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

RgbToYuv

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from Red-Green-Blue into YUV.

Syntax

```
void avl::RgbToYuv
(
 const avl::Image& inRgbImage,
 avl::Image& outYuvImage
)
```

Parameters

	Name	Type	Default	Description
→	inRgbImage	const Image&		
←	outYuvImage	Image&		

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8 bit image in RgbToYuv.
DomainError	Not supported inRgbImage pixel format in RgbToYuv. Supported formats: 3xUInt8.

SplitBayerImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates several monochromatic images from individual pixels of the input Bayer pattern image.

Syntax

```
void avl::SplitBayerImage
(
 const avl::Image& inBayerImage,
 avl::Image& outImage1,
 avl::Image& outImage2,
 avl::Image& outImage3,
 avl::Image& outImage4
)
```

Parameters

	Name	Type	Default	Description
→	inBayerImage	const Image&		
←	outImage1	Image&		First output image
←	outImage2	Image&		Second output image
←	outImage3	Image&		Third output image
←	outImage4	Image&		Fourth output image

Requirements

For input **inBayerImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input image must have even dimensions in SplitBayerImage.
DomainError	Only one channel input image is allowed in SplitBayerImage.
DomainError	Not supported inBayerImage pixel format in SplitBayerImage. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

XyzToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from XYZ to Red-Green-Blue.

Applications: XYZ color space is designed for human perception - not recommended for machine vision.

Syntax

```
void avl::XyzToRgb
(
 const avl::Image& inXyzImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inXyzImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inXyzImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when pixel type is uint8).

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in XyzToRgb.
DomainError	Not supported inXyzImage pixel format in XyzToRgb. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

YCoCgRToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from pseudointensitY-Orange-Green-with-Reversibility into Red-Green-Blue.

Syntax

```
void avl::YCoCgRToRgb
(
 const avl::Image& inYCoCgRImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inYCoCgRImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inYCoCgRImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in YCoCgRToRgb.
DomainError	Not supported inYCoCgRImage pixel format in YCoCgRToRgb. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

YCoCgToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from pseudointensitY-Orange-Green into Red-Green-Blue.

Syntax

```
void avl::YCoCgToRgb
(
 const avl::Image& inYCoCgImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inYCoCgImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inYCoCgImage** only pixel formats are supported: 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel image in YCoCgToRgb.
DomainError	Not supported inYCoCgImage pixel format in YCoCgToRgb. Supported formats: 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

Yuv442ToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts a YUV-encoded image into RGB color space.

Syntax

```
void avl::Yuv442ToRgb
(
 const avl::Image& inYuvImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inYuvImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inYuvImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in Yuv442ToRgb.
DomainError	Not an even width of a YUV image in Yuv442ToRgb.
DomainError	Not supported inYuvImage pixel format in Yuv442ToRgb. Supported formats: 3xUInt8.

YuvToRgb

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Converts color space from YUV into Red-Green-Blue.

Syntax

```
void avl::YuvToRgb
(
 const avl::Image& inYuvImage,
 avl::Image& outRgbImage
)
```

Parameters

	Name	Type	Default	Description
→	inYuvImage	const Image&		
←	outRgbImage	Image&		

Requirements

For input **inYuvImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8 bit image in YuvToRgb.
DomainError	Not supported inYuvImage pixel format in YuvToRgb. Supported formats: 3xUInt8.

55. OAuth

Table of content:

- BeginOAuthAuthorization
- EndOAuthAuthorization
- InitOAuth_Google
- InitOAuth_Microsoft
- RefreshOAuthToken
- RevokeOAuthAccess

BeginOAuthAuthorization

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Begins the OAuth 2.0 device authorization flow.

Syntax

```
void avl::BeginOAuthAuthorization
(
 avl::OAuthProvider::Type inProvider,
 atl::Conditional<atl::String>& outVerificationUrl,
 atl::Conditional<atl::String>& outUserCode,
 atl::Conditional<atl::String>& diagResponse
)
```

Parameters

	Name	Type	Default	Description
➡	inProvider	OAuthProvider::Type		Authorization provider
⬅	outVerificationUrl	Conditional<String>&		Verification URL the user need to visit.
⬅	outUserCode	Conditional<String>&		User Code to pass at the verification site.
🔍	diagResponse	Conditional<String>&		Raw response from the server

EndOAuthAuthorization

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Waits until the verification flow is completed at the verification url. Once the flow is ended, retrieves the information of the currently signed in OAuth user.

Syntax

```
void avl::EndOAuthAuthorization
(
 avl::OAuthProvider::Type inProvider,
 const atl::Optional<int>& inTimeout,
 atl::Conditional<avl::OAuthUser>& outUser,
 atl::Conditional<atl::String>& outError
)
```

Parameters

	Name	Type	Default	Description
➡	inProvider	OAuthProvider::Type		Authorization provider
➡	inTimeout	const Optional<int>&	NIL	The timeout in milliseconds.
⬅	outUser	Conditional<OAuthUser>&		The authenticated OAuth user or NIL if the timeout has elapsed.
⬅	outError	Conditional<String>&		

InitOAuth_Google

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Sets up the OAuth 2.0 framework for Google Authorization.

Syntax

```
void avl::InitOAuth_Google
(
 const atl::String& inClientId,
 const atl::String& inClientSecret,
 const atl::Optional<atl::Array<atl::String>>& inAdditionalScope = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
➡	inClientId	const String&		Google ClientId.
➡	inClientSecret	const String&		Google ClientSecret.
➡	inAdditionalScope	const Optional<Array<String>>&	NIL	Scope that is added to the minimal required scope

InitOAuth_Microsoft

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Sets up the OAuth 2.0 framework for Microsoft Authorization.

Syntax

```
void avl::InitOAuth_Microsoft
(
 const atl::String& inClientId,
 const atl::String& inTenant,
 const atl::Optional<atl::Array<atl::String>>& inAdditionalScope = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
➡	inClientId	const String&		Microsoft ClientId.
➡	inTenant	const String&		GUID or friendly name of the tenant.
➡	inAdditionalScope	const Optional<Array<String>>&	NIL	Scope that is added to the minimal required scope

RefreshOAuthToken

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Requests for refreshing current OAuth token.

Syntax

```
void avl::RefreshOAuthToken
(
 avl::OAuthProvider::Type inProvider,
 const atl::String& inRefreshToken,
 atl::Conditional<avl::OAuthUser>& outRefreshedUser,
 atl::Conditional<atl::String>& diagResponse
)
```

Parameters

	Name	Type	Default	Description
→	inProvider	OAuthProvider::Type		Authorization provider
→	inRefreshToken	const String&		Refresh token.
←	outRefreshedUser	Conditional<OAuthUser>&		The user authenticated with the refresh token.
🔍	diagResponse	Conditional<String>&		Raw response from the server

RevokeOAuthAccess

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Revokes the current OAuth access.

Syntax

```
void avl::RevokeOAuthAccess
(
 avl::OAuthProvider::Type inProvider
)
```

Parameters

	Name	Type	Default	Description
→	inProvider	OAuthProvider::Type		Authorization provider

56. Image Local Transforms

BottomHatImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological black top hat (bottom hat) operation on a image using a predefined kernel.

Syntax

```
void avl::BottomHatImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Selects kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height
←	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

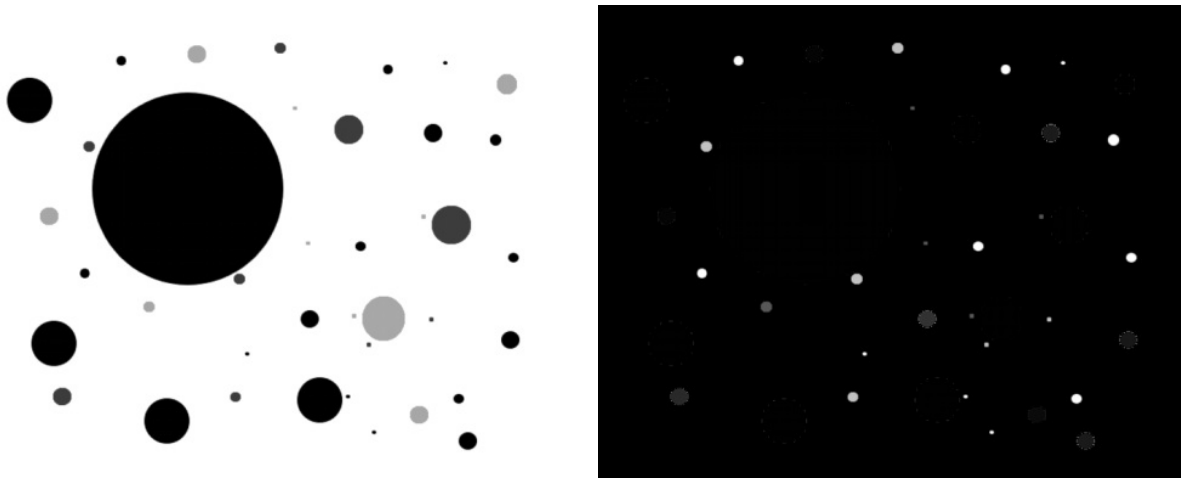
Read more about In-place Computation.

Description

Extracts from image small objects that are darker than surroundings.

Is performed by running consecutively two filters. CloseImage to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



*Bottom Hat used to remove bigger objects. Used parameters **inKernel**=Ellipse and **inRadiusX**=6. Source image on the left and result on the right.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in BottomHatImage.

BottomHatImage_AnyKernel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological black top hat (bottom hat) operation on a image using an arbitrary kernel.

Syntax

```
void avl::BottomHatImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Selects kernel shape
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

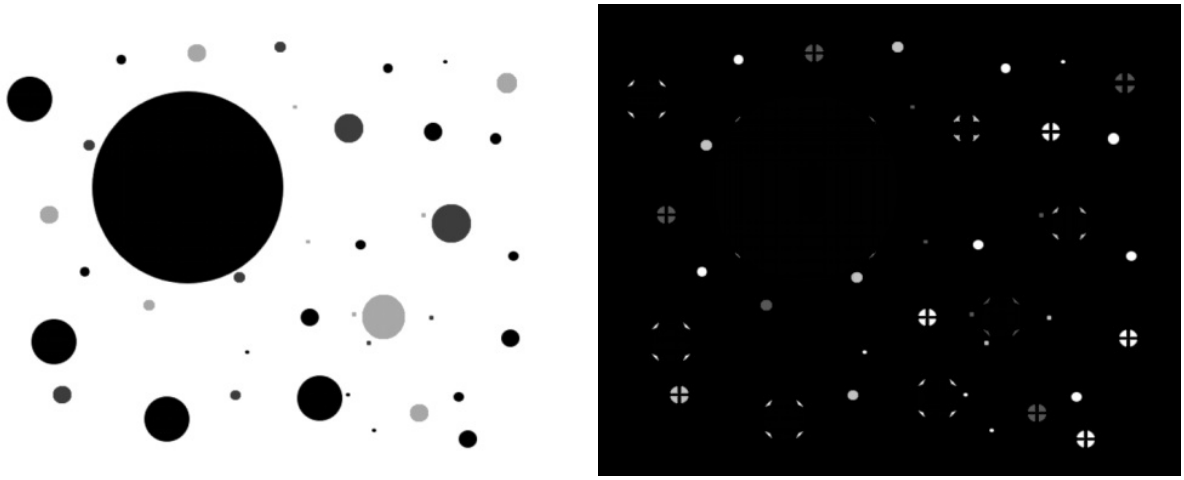
Read more about In-place Computation.

Description

Extracts from image small objects that are darker than surroundings. Uses user-defined kernel.

Is performed by running consecutively two filters. CloseImage_AnyKernel to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



Bottom Hat used to remove bigger objects. Source image on the left and result on the right.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in BottomHatImage_AnyKernel.

BottomHatImage_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological black top hat (bottom hat) operation on a image using a predefined mask.

Syntax

```
void avl::BottomHatImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	MorphologyKernel::Type		Selects kernel shape
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

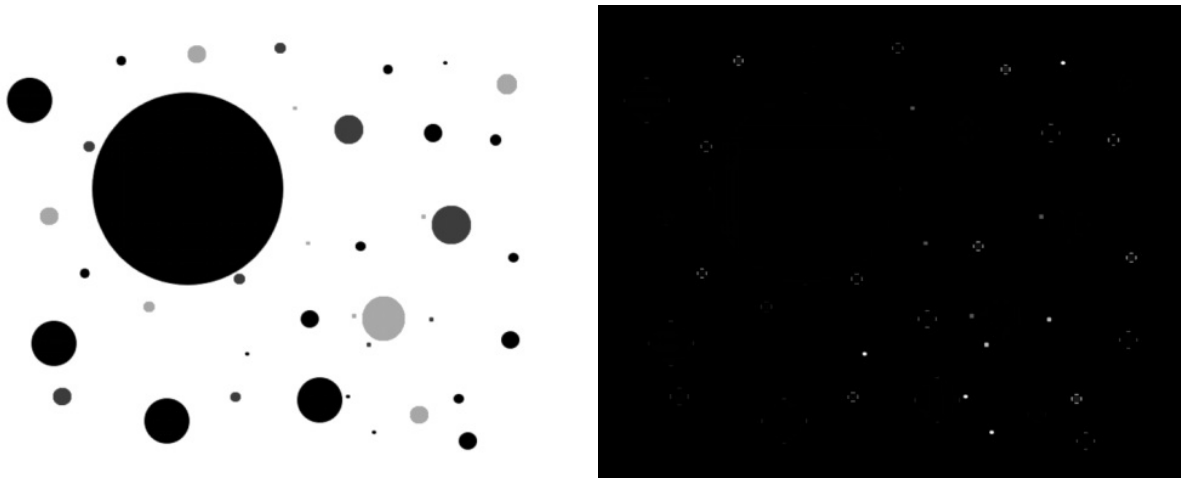
Read more about In-place Computation.

Description

Extracts from image small objects that are darker than surroundings. Uses predefined mask.

Is performed by running consecutively two filters. CloseImage_Mask to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



*Bottom Hat used to remove bigger objects. Used parameters **inKernel**=Box5x5. Source image on the left and result on the right.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in BottomHatImage_Mask.

Also in AVL Lite

CloseImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small dark structures from an image (or fills in bright ones) by applying consecutive dilation and erosion.

Applications: E.g. removal of the "pepper" component of salt-and-pepper noise.

Syntax

```
void avl::CloseImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

Parameters

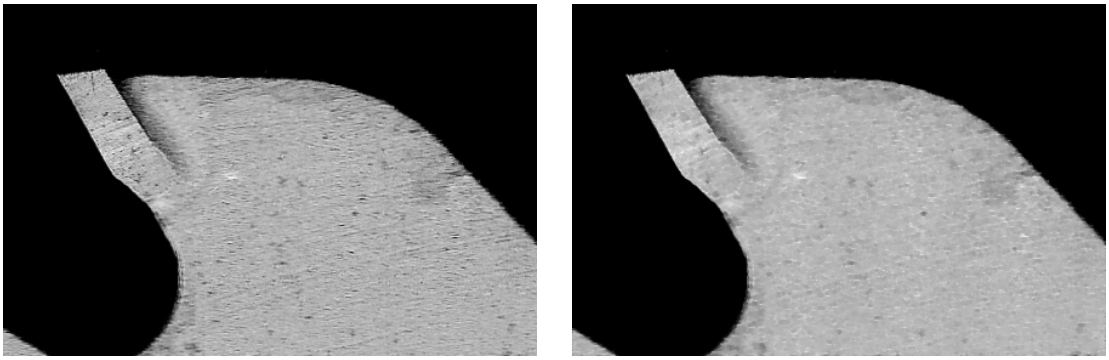
	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
➡	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
➡	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
➡	inKernel	KernelShape::Type			Selects kernel shape
➡	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
➡	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height
⬅	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Examples



CloseImage *used to remove dark scratches from an image.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CloseImage.

CloseImage_AnyKernel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small dark structures from an image (or fills in bright ones) by applying consecutive dilation and erosion.

Applications: E.g. removal of the "pepper" component of salt-and-pepper noise.

Syntax

```
void avl::CloseImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CloseImage_AnyKernel.

CloseImage_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small dark structures from an image (or fills in bright ones) by applying consecutive dilation and erosion.

Applications: E.g. removal of the "pepper" component of salt-and-pepper noise.

Syntax

```
void avl::CloseImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	MorphologyKernel::Type		Selects kernel shape
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in CloseImage_Mask.
DomainError	Unsupported kernel shape in CloseImage_Mask.

ConvolveImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a convolution of the input image with a user-specified mask.

Applications: Non-standard local transforms defined by the user.

Syntax

```
void avl::ConvolveImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Matrix& inMask,
 bool inNormalizeMaskValues,
 atl::Optional<const avl::Location&> inMaskOrigin,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inMask	const Matrix&		Image convolution kernel
→	inNormalizeMaskValues	bool	False	Normalize sum of weights in mask to one
→	inMaskOrigin	Optional<const Location&>	NIL	Relative location of point to its mask
←	outImage	Image&		Output image

Description

The operation computes new value of pixel as a convolution of **inImage** pixels and the **inMask** values. Pixels which mask exceeds **inRoi** region are set to black. Input and output pixel have the same type. If result value does not fit into pixel type you should use ConvertPixelType.

Examples

ConvolveImage *performed on the sample image with* ***inMask*** $\begin{pmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{pmatrix}$.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when inRoi=NIL).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty convolution mask on input in ConvolveImage.
DomainError	Mask origin is outside the dimensions of the mask in ConvolveImage.
DomainError	Region exceeds an input image in ConvolveImage.
DomainError	Sum of weights in Mask is equal zero. Cannot normalize values in ConvolveImage.

DifferenceOfGaussians

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Applies difference of Gaussians on an image, i.e. computes difference of two Gaussian smoothed images.

Applications: Emphasizes high-frequency image features such as lines or patches / dots.

Syntax

```
void avl::DifferenceOfGaussians
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDev,
 float inStdDevRatio,
 float inKernelRelativeSize,
 float inScale,
 avl::Image& outImage,
 avl::Profile& diagKernelShape
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of output pixels to be computed
→	inStdDev	float	0.0 – ∞	3.0f	Smoothing standard deviation for the smaller kernel
→	inStdDevRatio	float	1.0 – ∞	1.6f	Defines how many times larger is the second kernel
→	inKernelRelativeSize	float	0.0 – 3.0	3.0f	A multiple of the standard deviation determining the size of the kernel
→	inScale	float		1.0f	Output image scaling factor
←	outImage	Image&			Output image
🔍	diagKernelShape	Profile&			Middle row of the kernel being used

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE41 technology for pixels of type: UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in DifferenceOfGaussians.

DilateAndErodeImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Calculates dilation and erosion simultaneously for faster execution.

Syntax

```
void avl::DilateAndErodeImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outDilated,
 avl::Image& outEroded
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be read
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outDilated	Image&			
←	outEroded	Image&			

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inBorderColor is relevant only when inSourceRoi is set to Auto (NIL) in DilateAndErodeImage.
DomainError	Not supported kernel on input in DilateAndErodeImage.
DomainError	Region exceeds an input image in DilateAndErodeImage.

Also in AVL Lite

DilateImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the maximum of pixels within a kernel.

Applications: Thickens bright features in an images and thins dark ones.

Syntax

```
void avl::DilateImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

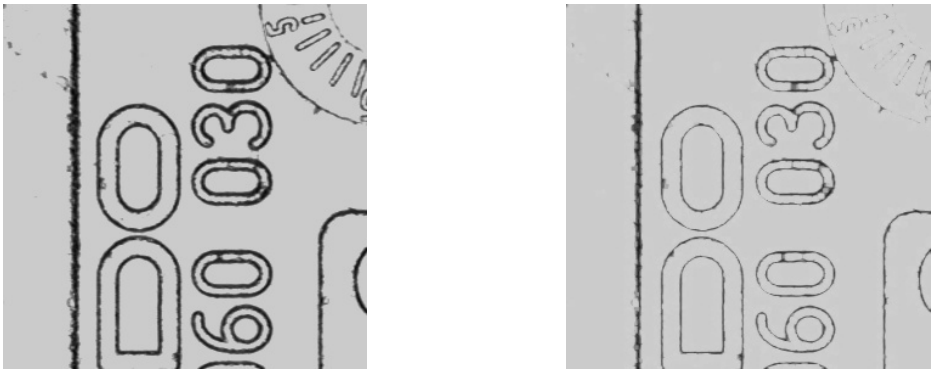
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

Description

The operation replaces each pixel with the brightest pixel in its neighbourhood, thus shrinking dark areas in **inImage** and expanding the bright ones.

Examples



DilateImage *performed on the sample image with* ***inKernel*** *= Box,* ***inRadiusX*** *= 1,* ***inRadiusY*** *= 1.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inBorderColor is relevant only when inSourceRoi is set to Auto (NIL) in DilateImage.
DomainError	Not supported kernel on input in DilateImage.
DomainError	Region exceeds an input image in DilateImage.

See Also

- ErodeImage – Replaces each pixel with the minimum of pixels within a kernel.

DilateImage_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationPro

Replaces each pixel with the maximum of pixels within an arbitrary kernel.

Syntax

```
void avl::DilateImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape (any)
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when inRoi=NIL, inSourceRoi=NIL, inBorderColor=NIL).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in DilateImage_AnyKernel.
DomainError	Region exceeds an input image in DilateImage_AnyKernel.

Also in AVL Lite

DilateImage_Mask

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the maximum of pixels within a small rectangular kernel.

Syntax

```
void avl::DilateImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inKernel	MorphologyKernel::Type		Selects a predefined kernel
←	outImage	Image&		Output image

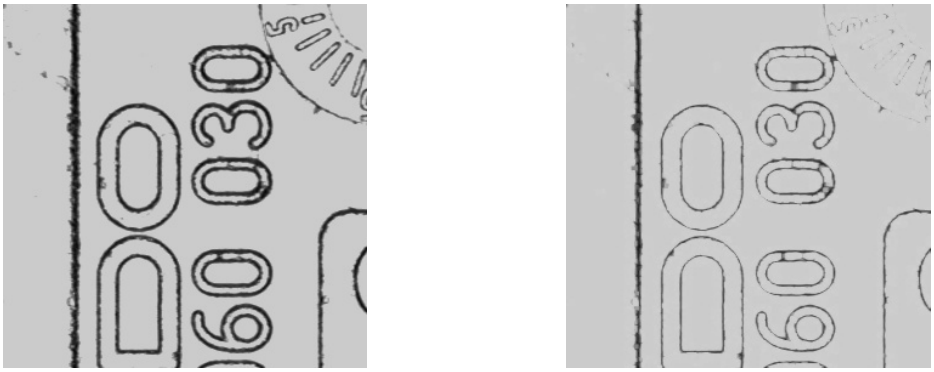
Description

The operation replaces each pixel with the brightest pixel in its neighbourhood, thus shrinking dark areas in **inImage** and expanding the bright ones.

This filter is a simplified version of DilateImage. It is limited to only a few symmetric kernels and supports only basic ROI handling.

Please note that on some machines the filter execution time can be greater than execution time of the corresponding DilateImage filter.

Examples



DilateImage_Mask *performed on the sample image with* ***inKernel*** *= Box3x3.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, SINT16, UINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in DilateImage_Mask.

See Also

ErodeImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the minimum of pixels within a kernel.

Applications: Thins bright features in an image and thickens dark ones.

Syntax

```
void avl::ErodeImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

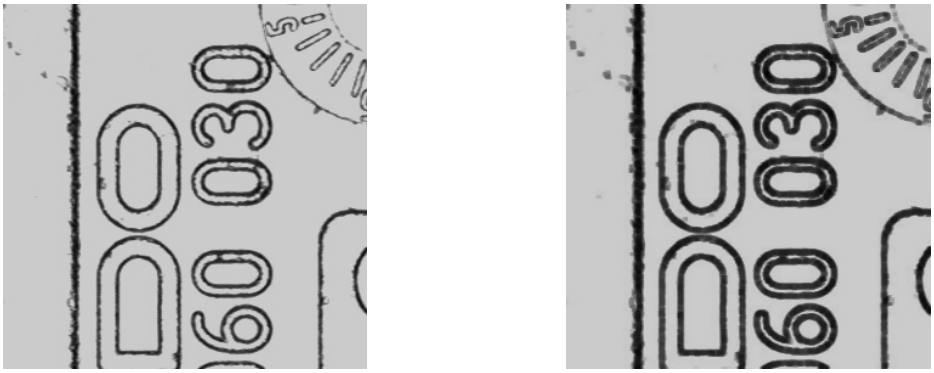
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

Description

The operation replaces each pixel with the darkest pixel in its neighbourhood, thus shrinking bright areas in **inImage** and expanding the dark ones.

Examples



ErodeImage *performed on the sample image with* ***inKernel*** *= Box,* ***inRadiusX*** *= 1,* ***inRadiusY*** *= 1.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inBorderColor is relevant only when inSourceRoi is set to Auto (NIL) in ErodeImage.
DomainError	Not supported kernel on input in ErodeImage.
DomainError	Region exceeds an input image in ErodeImage.

See Also

- DilateImage – Replaces each pixel with the maximum of pixels within a kernel.

ErodeImage_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationPro

Replaces each pixel with the minimum of pixels within an arbitrary kernel.

Syntax

```
void avl::ErodeImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape (any)
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when inRoi=NIL, inSourceRoi=NIL, inBorderColor=NIL).

Errors

DomainError	Region exceeds an input image in ErodeImage_AnyKernel.

Also in AVL Lite

ErodeImage_Mask

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the minimum of pixels within a small rectangular kernel.

Syntax

```
void avl::ErodeImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inKernel	MorphologyKernel::Type		Selects a predefined kernel
←	outImage	Image&		Output image

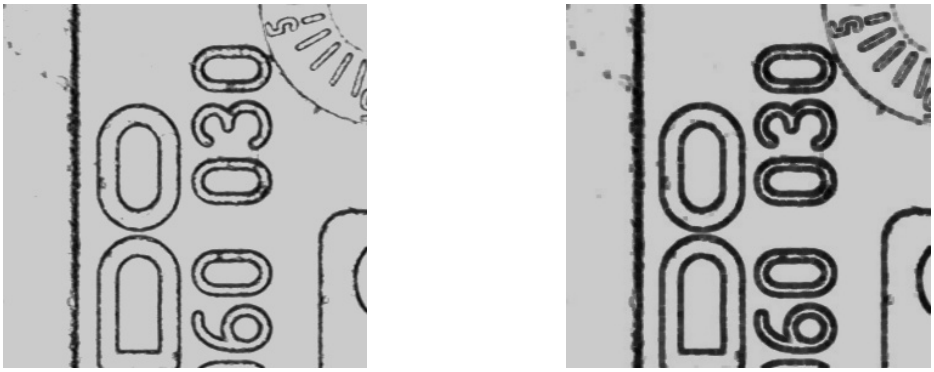
Description

The operation replaces each pixel with the darkest pixel in its neighbourhood, thus shrinking bright areas in **inImage** and expanding the dark ones.

This filter is a simplified version of ErodeImage. It is limited to only a few symmetric kernels and supports only basic ROI handling.

Please note that on some machines the filter execution time can be greater than execution time of the corresponding ErodeImage filter.

Examples



ErodeImage_Mask *performed on the sample image with* ***inKernel*** *= Box3x3.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, SINT16, UINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

GradientDirAndPresenceImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an image of gradient directions mapped to the range from 1 to 255. Zero means "no edge".

Applications: For highly optimized analysis of gradient directions.

Syntax

```
void avl::GradientDirAndPresenceImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientMaskOperator::Type inOperator,
 float inEdgeThreshold,
 avl::AngleRange::Type inAngleRange,
 avl::Image& outDirectionsImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of output pixels to be computed
→	inOperator	GradientMaskOperator::Type			Defines how the gradient is computed
→	inEdgeThreshold	float	0.01 – ∞	10.0f	Minimum edge magnitude (other pixels will be set to 0)
→	inAngleRange	AngleRange::Type		_0_360	Range of output angles
←	outDirectionsImage	Image&			

Description

The operation computes the angle of the intensity change direction at each pixel of the **inImage**. Firstly the selected **inOperator** is used to obtain two-dimensional gradient vector at each pixel. When this vector length exceeds **inEdgeThreshold** the angle of the vector is calculated, scaled and stored in **outDirectionsImage** pixel.

This operation always generates a single-channel image with the uint8 pixel type on the output, regardless of the input image format, with following pixel values:

- When gradient length does not exceed threshold, the value of 0 is stored in pixel.
- When gradient length exceeds threshold, its angle is scaled to range 0..255 and stored in pixel value.

When a pixel value is non-zero, one can restore the original angle with the formula:

```
double angle = value * 360.0 / 255.0;   // if inAngleRange == _0_360
double angle = value * 180.0 / 255.0;   // if inAngleRange == _0_180
double angle = value * 90.0 / 255.0;    // if inAngleRange == _0_90
```

To measure the angular distance between two directions described by two non-zero pixel values, use the following formulas:

```
   int valueDif = abs(inValue1 - inValue2);
double angleDif = (valueDif < 128 ? (double)valueDif : (255.0 - valueDif)) * 360.0 / 255.0;  // if inAngleRange ==
_0_360
 double angleDif = ((double)valueDif) * 180.0 / 255.0;                                       // if inAngleRange ==
_0_180
 double angleDif = ((double)valueDif) * 90.0 / 255.0;                                        // if inAngleRange ==
_0_90
```

Hardware Acceleration

This operation is optimized for SSE41 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in GradientDirAndPresenceImage.

See Also

- GradientMagnitudeImage – Measures the strength of gradient at each pixel location.

GradientImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a gradient image with smoothing operator of any size. The output pixels are signed.

Syntax

```
void avl::GradientImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientOperator::Type inOperator,
 const float inStdDevX,
 atl::Optional<float> inStdDevY,
 avl::Image& outGradientImage,
 avl::Image& diagGradientDirections
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outGradientImage pixels to be computed
→	inOperator	GradientOperator::Type			Defines how the gradient is computed
→	inStdDevX	const float	0.0 – ∞	2.0f	Horizontal smoothing standard deviation
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Vertical smoothing standard deviation
←	outGradientImage	Image&			Gradients of the image
🔍	diagGradientDirections	Image&			Gradient directions presented in a human readable format

Remarks

Please note that about a half of the pixels will be negative and in the preview windows they will be displayed as black.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in GradientImage.

GradientImage_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a gradient image with a Sobel or Prewitt operator.

Syntax

```
void avl::GradientImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientMaskOperator::Type inOperator,
 const int inScale,
 avl::Image& outGradientImage,
 avl::Image& diagGradientDirections
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outGradientImage pixels to be computed
→	inOperator	GradientMaskOperator::Type			Defines how the gradient is computed
→	inScale	const int	1 – 16	1	Scales the resulting gradients
←	outGradientImage	Image&			Gradients of the image
🔍	diagGradientDirections	Image&			Gradient directions presented in a human readable format

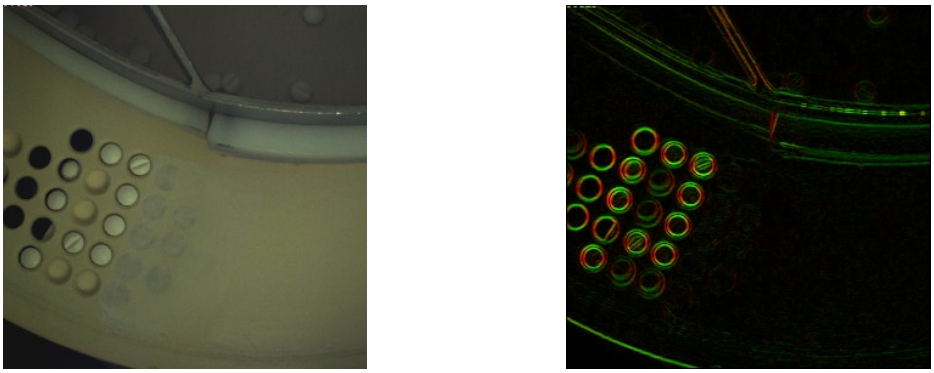
Description

The operation computes the image gradient, which is directional change of the image intensity at each pixel. Each pixel of the resulting two-channel **outGradientImage** represents the gradient at the corresponding **inImage** pixel as a two-dimensional vector (each dimension on a separate, signed image channel). The length and direction of the vector represents the strength and direction of the intensity change.

Note that the format of the resulting image is not perfectly legible for a human eye. Firstly, the resulting image contains negative values. Secondly, directions of the gradients are represented indirectly.

- To extract information about the sole **strength** of the intensity change one could use GradientMagnitudeImage filter.

Examples



GradientImage_Mask *performed on the sample image with* ***inOperator*** *= Sobel. Image on the right is actually an absolute value of the resulting* ***outGradientImage****, so negative pixel values are also visible.*

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in GradientImage_Mask.

See Also

- GradientImage – Computes a gradient image with smoothing operator of any size. The output pixels are signed.
- GradientMagnitudeImage – Measures the strength of gradient at each pixel location.

GradientMagnitudeImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the strength of gradient at each pixel location.

Syntax

```
void avl::GradientMagnitudeImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientMaskOperator::Type inOperator,
 avl::MagnitudeMeasure::Type inMeasure,
 const int inScale,
 avl::Image& outValueImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of output pixels to be computed
→	inOperator	GradientMaskOperator::Type			Defines how the gradient is computed
→	inMeasure	MagnitudeMeasure::Type		Hypot	Defines how the gradient magnitude is computed
→	inScale	const int	1 – 16	1	Scales the resulting gradient magnitudes
←	outValueImage	Image&			Gradient magnitudes of the image

Description

The operation computes the magnitude of the intensity change at each pixel of the **inImage**. Firstly the selected **inOperator** is used to obtain two-dimensional gradient vector at each pixel. Then the magnitudes of the vectors are estimated using the **inMeasure** method.

Specified by **inMeasure** method computes magnitude (A) from horizontal gradient component (x) and vertical gradient component (y) using one of following formulas:

$$A_{Horizontal} = |x|$$

$$A_{Vertical} = |y|$$

$$A_{Average} = \frac{|x| + |y|}{2}$$

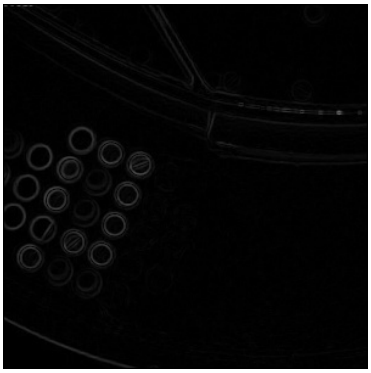
$$A_{Sum} = |x| + |y|$$

$$A_{Maximum} = Max(|x|, |y|)$$

$$A_{Hypot} = \sqrt{x^2 + y^2}$$

The magnitudes are multiplied by **inScale** factor and saturated if they exceed the greatest value of their type.

Examples



GradientMagnitudeImage *performed on the sample image with* ***inOperator*** *= Sobel,* ***inMeasure*** *= Hypot.*

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in GradientMagnitudeImage.

See Also

- GradientImage_Mask – Computes a gradient image with a Sobel or Prewitt operator.
- GradientImage – Computes a gradient image with smoothing operator of any size. The output pixels are signed.

GradientMagnitudeImage_Signed

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an image of gradient for only selected direction.

Applications: For highly optimized analysis of gradient directions.

Syntax

```
void avl::GradientMagnitudeImage_Signed
(
 const avl::Image& inImage,
 avl::EdgeTransition::Type inEdgeTransition,
 avl::DifferentiationMethod::Type inDiffMethod,
 avl::GradientOrientation::Type inGradientOrientation,
 bool inSigned,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inEdgeTransition	EdgeTransition::Type		Defines what is considered as an edge in the image.
→	inDiffMethod	DifferentiationMethod::Type		Defines which finite difference approach to use
→	inGradientOrientation	GradientOrientation::Type		Defines which gradient orientation to compute
→	inSigned	bool	False	Defines whether or not to output a signed result (true) or just a positive result (false)
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation is optimized for SSE41 technology for pixels of type: UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in GradientMagnitudeImage_Signed. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

OpenImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small bright structures from an image (or fills in dark ones) by applying consecutive erosion and dilation.

Applications: E.g. removal of the "salt" component of salt-and-pepper noise.

Syntax

```
void avl::OpenImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

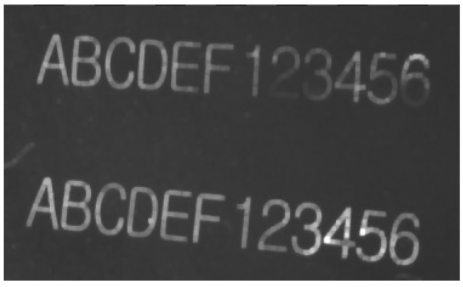
In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Examples

Input image with salt-and-pepper noise.



Result of applying OpenImage.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in OpenImage.

OpenImage_AnyKernel

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small bright structures from an image (or fills in dark ones) by applying consecutive erosion and dilation.

Applications: E.g. removal of the "salt" component of salt-and-pepper noise.

Syntax

```
void avl::OpenImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

Read more about In-place Computation.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in OpenImage_AnyKernel.

OpenImage_Mask

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes small bright structures from an image (or fills in dark ones) by applying consecutive erosion and dilation.

Applications: E.g. removal of the "salt" component of salt-and-pepper noise.

Syntax

```
void avl::OpenImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	MorphologyKernel::Type		Kernel shape
←	outImage	Image&		Output image

In-place Processing

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in OpenImage_Mask.
DomainError	Unsupported kernel shape in OpenImage_Mask.

SmoothImage_Bilateral

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths an image while preserving sharp edges.

Syntax

```
void avl::SmoothImage_Bilateral
(
 const avl::Image& inImage,
 atl::Optional<const avl::Image&> inEdgesImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inDistanceSigma,
 const float inColorSigma,
 avl::BilateralSamplingMethod::Type inSamplingMethod,
 const int inIterationCount,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inEdgesImage	Optional<const Image&>		NIL	Image to be used for edge detection
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inDistanceSigma	const float	0.0 – 128.0	5.0f	Sigma used when calculating the gaussian difference two pixel positions
→	inColorSigma	const float	0.0 – ∞	35.0f	Sigma used when calculating the gaussian difference between two colors
→	inSamplingMethod	BilateralSamplingMethod::Type		Poisson	Whether to use a naive (full) or a subsampling method
→	inIterationCount	const int	1 – ∞	1	Determines how many times the bilateral filter will be run
←	outImage	Image&			Output image

Description

The bilateral filter is a low pass filtering algorithm weighting pixels not just in the spatial domain (which is what the gaussian filter does) but also in the color domain. This allows the filter to consider only the pixels that are both nearby and similar in color. The resulting image is smoothed but sharp edges are maintained.

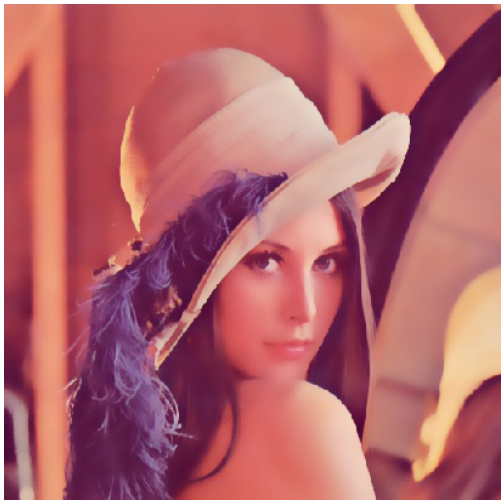
A different image can be used for color distance calculations if the **inEdgesImage** parameter is set. This allows to transfer edges from other images or preserve edges only for part of an image.

The filter can be run in a iterative mode. When **inIterationCount** is set to a value greater than 1 the filter runs **inIterationCount** times using the result from the previous iteration as the edges image in the next.

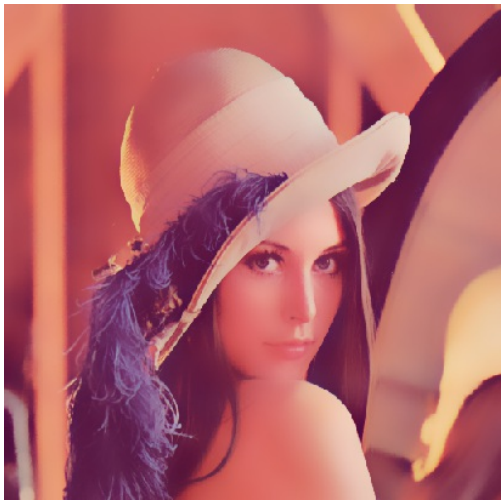
The algorithm is computationally complex so, if high accuracy is not needed, Poisson Disk subsampling can be used to significantly speed up the algorithms execution time with minimal looses in quality.

Examples

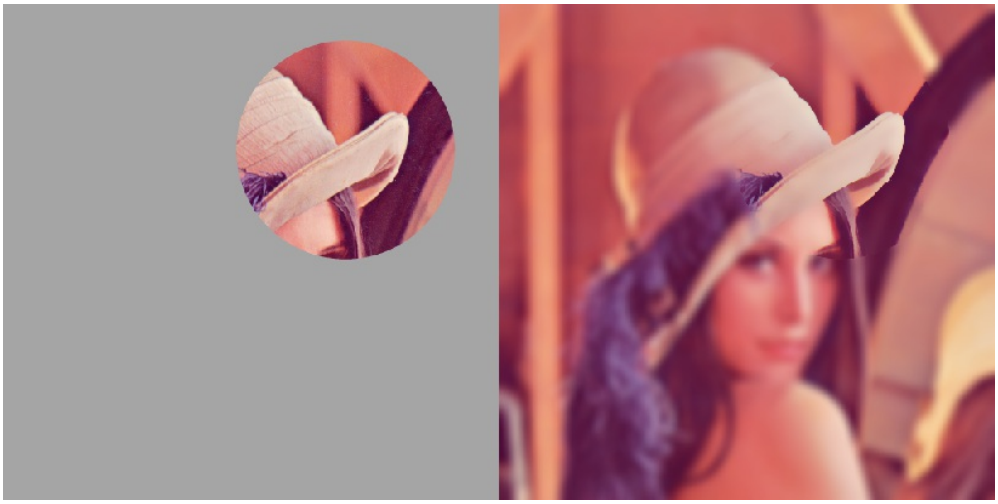
Example input image



Output image with distance sigma set to 5 and color sigma set to 35

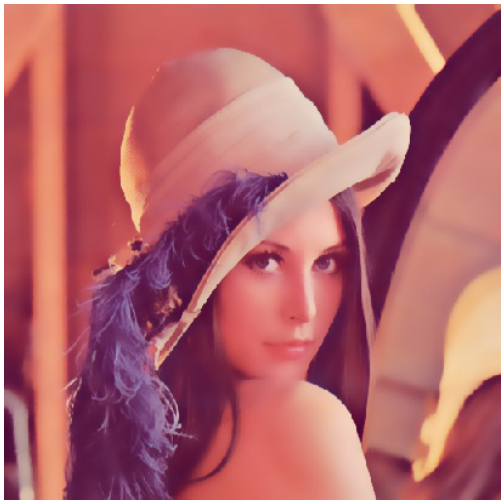


Output image with distance sigma set to 10 and color sigma set to 35

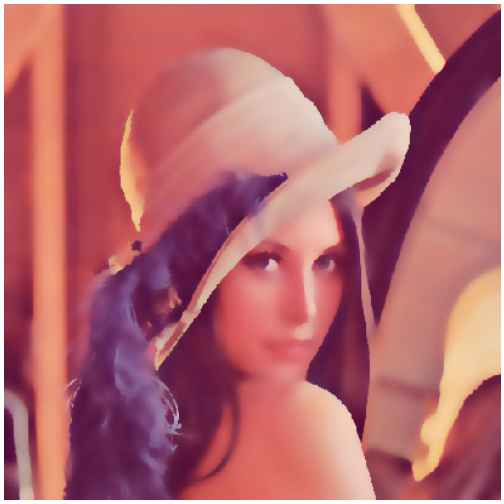


Edges image that is grey everywhere outside of a circle and the resulting output image.

Edges image which is different from the input image and the resulting output image.



Output image with distance sigma set to 5 and color sigma set to 35 after one iteration



Output image with distance sigma set to 5 and color sigma set to 35 after three iterations

Remarks

The **inDistanceSigma** parameter behaves similarly to standard deviation in the gaussian filter.

Higher values of **inColorSigma** allow the filter to blend pixel that differ more in terms of color.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image and edges image must be of the same size in SmoothImage_Bilateral.
DomainError	Image and edges image must be of the same type in SmoothImage_Bilateral.
DomainError	Image and edges image must have the same depth in SmoothImage_Bilateral.
DomainError	Region exceeds an input image in SmoothImage_Bilateral.

See Also

- SmoothImage_Gauss – Smooths an image using a gaussian kernel.

SmoothImage_Deriche

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an image using Deriche filter.

Applications: Approximation of the gaussian filter, which can be faster for large kernels.

Syntax

```
void avl::SmoothImage_Deriche
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inAlphaX,
 atl::Optional<float> inAlphaY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of output pixels to be computed
→	inAlphaX	const float	0.001 – ∞	0.5f	Horizontal coefficient
→	inAlphaY	Optional<float>	0.001 – ∞	NIL	Vertical coefficient
←	outImage	Image&			Output image

Hints

- To make smoothing stronger, decrease the **inAlphaX** and – optionally – **inAlphaY**.
- If the smoothing kernel is not very big, it is recommended to use SmoothImage_Gauss instead.

Examples

SmoothImage_Deriche *performed on a sample image with* ***inAlphaX*** *= 0.5.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SmoothImage_Deriche.

SmoothImage_DirAndPresence

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths the result of GradientDirAndPresenceImage.

Syntax

```
void avl::SmoothImage_DirAndPresence
(
 const avl::Image& inDirectionsImage,
 const int inRadiusX,
 atl::Optional<int> inRadiusY,
 const int inQuantizationLevel,
 const int inMinSampleCount,
 avl::Image& outDirectionsImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDirectionsImage	const Image&			
→	inRadiusX	const int	0 – ∞	1	Horizontal radius of the kernel (width is 2r+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Vertical radius of the kernel (height is 2r+1)
→	inQuantizationLevel	const int	1 – 5	5	Determines angular quantization level; the lower the better but slower
→	inMinSampleCount	const int	1 – ∞	1	A window is evaluated to 0 if it contains less than this number of non-zero pixels
←	outDirectionsImage	Image&			

Errors

List of possible exceptions:

Error type	Description
DomainError	The result of GradientDirAndPresenceImage (of type 1xUInt8) should be provided in inGradientDirAndPresenceImage in SmoothImage_DirAndPresence.

SmoothImage_Gauss

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an image using a gaussian kernel.

Applications: Removal of gaussian noise from images.

Syntax

```
void avl::SmoothImage_Gauss
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 const float inKernelRelativeSize,
 avl::Image& outImage,
 int& diagKernelRadiusX,
 int& diagKernelRadiusY
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of output pixels to be computed
→	inStdDevX	float	0.0 – ∞	1.0f	Horizontal smoothing standard deviation
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Vertical smoothing standard deviation
→	inKernelRelativeSize	const float	0.0 – 3.0	2.0f	A multiple of the standard deviation determining the size of the kernel
←	outImage	Image&			Output image
🔍	diagKernelRadiusX	int&			Horizontal radius of Gaussian kernel being used
🔍	diagKernelRadiusY	int&			Vertical radius of Gaussian kernel being used

Hints

- To make smoothing stronger, increase the **inStdDevX** and – optionally – **inStdDevY**.
- Increase **inKernelRelativeSize** to achieve better quality at the cost of a bit longer execution time.
- For small kernels consider switching to SmoothImage_Gauss_Mask to achieve the highest performance.

Examples

SmoothImage_Gauss *performed on a sample image with* ***inStdDevX*** *= 3.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16, REAL.

This operation is optimized for SSE41 technology for pixels of type: UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT16, UINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT16, UINT16, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SmoothImage_Gauss.

SmoothImage_Gauss_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an image using a predefined gaussian kernel.

Applications: Removal of gaussian noise from images (fast).

Syntax

```
void avl::SmoothImage_Gauss_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GaussKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
➡	inImage	const Image&		Input image
➡	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
➡	inKernel	GaussKernel::Type	_3x3	Predefined Gauss kernel
⬅	outImage	Image&		Output image

Description

This operation is a simplified, fast in computation, version of SmoothImage_Gauss, with predefined kernel and simplified ROI handling.

Kernel used in operation can be chosen by **inKernel** parameter:

- **Box_2x2**: 3 by 3 pixels kernel similar to 2 by 2 gaussian kernel rotated by 45 degrees; with StdDev ≈ 0.6:

$$\frac{1}{8}\begin{bmatrix}0 & 1 & 0\\ 1 & (4) & 1\\ 0 & 1 & 0\end{bmatrix}$$

- **Box_3x3**: 3 by 3 pixels kernel with StdDev ≈ 0.85 of following form:

$$\frac{1}{16}\begin{bmatrix}1 & 2 & 1\\ 2 & (4) & 2\\ 1 & 2 & 1\end{bmatrix}$$

- **Box_4x4**: 5 by 5 pixels kernel with StdDev ≈ 0.91 of following form:

$$\frac{1}{256}\begin{bmatrix}1 & 4 & 6 & 4 & 1\\ 4 & 16 & 24 & 16 & 4\\ 6 & 24 & (36) & 24 & 6\\ 4 & 16 & 24 & 16 & 4\\ 1 & 4 & 6 & 4 & 1\end{bmatrix}$$

- **Box_5x5**: 5 by 5 pixels kernel with StdDev ≈ 1.1 of following form:

$$\frac{1}{169}\begin{bmatrix}1 & 3 & 5 & 3 & 1\\ 3 & 9 & 15 & 9 & 3\\ 5 & 15 & (25) & 15 & 5\\ 3 & 9 & 15 & 9 & 3\\ 1 & 3 & 5 & 3 & 1\end{bmatrix}$$

- **Box_6x6**: 5 by 5 pixels kernel with StdDev ≈ 1.25 of following form:

$$\frac{1}{196}\begin{bmatrix}4 & 6 & 8 & 6 & 4\\ 6 & 9 & 12 & 9 & 6\\ 8 & 12 & (16) & 12 & 8\\ 6 & 9 & 12 & 9 & 6\\ 4 & 6 & 8 & 6 & 4\end{bmatrix}$$

- **Box_7x7**: 7 by 7 pixels kernel with StdDev ≈ 1.7 of following form:

$$\frac{1}{256}\begin{bmatrix}1 & 2 & 3 & 4 & 3 & 2 & 1\\ 2 & 4 & 6 & 8 & 6 & 4 & 2\\ 3 & 6 & 9 & 12 & 9 & 6 & 3\\ 4 & 8 & 12 & (16) & 12 & 8 & 4\\ 3 & 6 & 9 & 12 & 9 & 6 & 3\\ 2 & 4 & 6 & 8 & 6 & 4 & 2\\ 1 & 2 & 3 & 4 & 3 & 2 & 1\end{bmatrix}$$

- **Box_8x8**: 9 by 9 pixels kernel with StdDev ≈ 1.85 of following form:

$$\frac{1}{1024}\begin{bmatrix}1 & 2 & 3 & 6 & 8 & 6 & 3 & 2 & 1\\ 2 & 4 & 6 & 12 & 16 & 12 & 6 & 4 & 2\\ 3 & 6 & 9 & 18 & 24 & 18 & 9 & 6 & 3\\ 6 & 12 & 18 & 36 & 48 & 36 & 18 & 12 & 6\\ 8 & 16 & 24 & 48 & (64) & 48 & 24 & 16 & 8\\ 6 & 12 & 18 & 36 & 48 & 36 & 18 & 12 & 6\\ 3 & 6 & 9 & 18 & 24 & 18 & 9 & 6 & 3\\ 2 & 4 & 6 & 12 & 16 & 12 & 6 & 4 & 2\\ 1 & 2 & 3 & 6 & 8 & 6 & 3 & 2 & 1\end{bmatrix}$$

- **Box_9x9**: 9 by 9 pixels kernel with StdDev ≈ 2.0 of following form:

$$\frac{1}{1089}\begin{bmatrix}1 & 2 & 4 & 6 & 7 & 6 & 4 & 2 & 1\\ 2 & 4 & 8 & 12 & 14 & 12 & 8 & 4 & 2\\ 4 & 8 & 16 & 24 & 28 & 24 & 16 & 8 & 4\\ 6 & 12 & 24 & 36 & 42 & 36 & 24 & 12 & 6\\ 7 & 14 & 28 & 42 & (49) & 42 & 28 & 14 & 7\\ 6 & 12 & 24 & 36 & 42 & 36 & 24 & 12 & 6\\ 4 & 8 & 16 & 24 & 28 & 24 & 16 & 8 & 4\\ 2 & 4 & 8 & 12 & 14 & 12 & 8 & 4 & 2\\ 1 & 2 & 4 & 6 & 7 & 6 & 4 & 2 & 1\end{bmatrix}$$

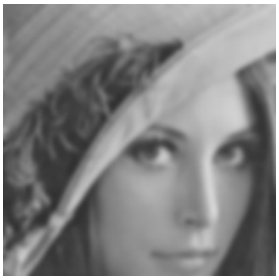
- **Box_11x11**: 11 by 11 pixels kernel with StdDev ≈ 2.2 of following form:

$$\frac{1}{4096}\begin{bmatrix}1 & 2 & 4 & 8 & 11 & 12 & 11 & 8 & 4 & 2 & 1\\ 2 & 4 & 8 & 16 & 22 & 24 & 22 & 16 & 8 & 4 & 2\\ 4 & 8 & 16 & 32 & 44 & 48 & 44 & 32 & 16 & 8 & 4\\ 8 & 16 & 32 & 64 & 88 & 96 & 88 & 64 & 32 & 16 & 8\\ 11 & 22 & 44 & 88 & 121 & 132 & 121 & 88 & 44 & 22 & 11\\ 12 & 24 & 48 & 96 & 132 & (144) & 132 & 96 & 48 & 24 & 12\\ 11 & 22 & 44 & 88 & 121 & 132 & 121 & 88 & 44 & 22 & 11\\ 8 & 16 & 32 & 64 & 88 & 96 & 88 & 64 & 32 & 16 & 8\\ 4 & 8 & 16 & 32 & 44 & 48 & 44 & 32 & 16 & 8 & 4\\ 2 & 4 & 8 & 16 & 22 & 24 & 22 & 16 & 8 & 4 & 2\\ 1 & 2 & 4 & 8 & 11 & 12 & 11 & 8 & 4 & 2 & 1\end{bmatrix}$$

Hints

- Select kernel size by setting the **inKernel** input.

Examples



SmoothImage_Gauss_Mask *performed on a sample image with* ***inKernel*** *= _11x11.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16.

This operation is optimized for SSE4.1 technology for pixels of types: Kernel 11x11 UINT8.

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SmoothImage_Gauss_Mask.

See Also

- SmoothImage_Mean_Mask – Smooths an image by averaging pixels within a small rectangular kernel.
- SmoothImage_Gauss – Smooths an image using a gaussian kernel.

SmoothImage_Mean

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an image by averaging pixels within a rectangular kernel.

Applications: Usually used for computing features related to local image "windows". Can be also used for noise removal, but Gauss is superior here.

Syntax

```
void avl::SmoothImage_Mean
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be read
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Description

Replaces each pixel with the average of all pixels contained in a rectangular kernel. The width of the kernel is **2 * inRadiusX + 1**, the height is **2 * inRadiusY + 1**. When **inRadiusY** is set to **Auto**, then its value is implicitly copied from **inRadiusX**.

Hints

- Define the size of the kernel by setting **inRadiusX** and – optionally – **inRadiusY**.
- Highest performance will be achieved with **inKernel** = Box. Other kernel shapes will result is longer execution time.
- Define **inSourceRoi** is some pixels of the input images should be ignored (advanced).

Examples

SmoothImage_Mean *performed on a sample image with* ***inRadiusX*** *= 4.*

Hardware Acceleration

This operation is optimized for PARALLEL SSE2 technology for pixels of types: UINT8, SINT8, SINT16, SINT32, REAL.

This operation is optimized for SSE41 technology for pixels of type: UINT16.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, SINT16, SINT32, REAL, UINT16.

This operation is optimized for NEON technology for pixels of types: UINT8, UINT16.

Errors

List of possible exceptions:

Error type	Description
DomainError	inBorderColor is relevant only when inSourceRoi is set to Auto (NIL) in SmoothImage_Mean.
DomainError	Not supported kernel on input in SmoothImage_Mean.
DomainError	Region exceeds an input image in SmoothImage_Mean.

SmoothImage_Mean_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths an image by averaging pixels within an arbitrary kernel.

Applications: Usually used for computing features related to local image "windows" having non-standard shape.

Syntax

```
void avl::SmoothImage_Mean_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape (any)
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

Hints

- Define the kernel shape by setting the **inKernel** input.
- Define the kernel center point by setting the **inKernelAnchor** input. If you leave it **NIL**, the mass center will be used.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in SmoothImage_Mean_AnyKernel.
DomainError	Region exceeds an input image in SmoothImage_Mean_AnyKernel.

See Also

- SmoothImage_Mean – Smooths an image by averaging pixels within a rectangular kernel.

Also in AVL Lite

SmoothImage_Mean_Mask

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an image by averaging pixels within a small rectangular kernel.

Applications: This is a faster alternative to SmoothImage_Mean when the kernel is very small.

Syntax

```
void avl::SmoothImage_Mean_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::MeanKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inKernel	MeanKernel::Type		Selects a predefined kernel
←	outImage	Image&		Output image

Description

This operation is a simplified, fast in computation, version of SmoothImage_Mean, with predefined kernel and simplified ROI handling.

Kernel used in operation can be chosen by **inKernel** parameter:

- **Box_3x3**: 3 by 3 pixels, the closest equivalent is SmoothImage_Mean call with **inKernel** = Box, **inRadiusX** = 1, **inRadiusY** = 1, **inIterationsCount** = 1
- **Box_5x5**: 5 by 5 pixels, the closest equivalent is SmoothImage_Mean call with **inKernel** = Box, **inRadiusX** = 2, **inRadiusY** = 2, **inIterationsCount** = 1

Although above calls are described as closest equivalent their results may vary.

Hints

- Choose kernel size by setting **inKernel** input.
- If a larger kernel is required, switch to SmoothImage_Mean.
- If you want to remove noises from an image, consider using SmoothImage_Gauss_Mask instead.

Examples

SmoothImage_Mean_Mask *performed on a sample image with* ***inKernel*** *= Box5x5.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT16.

This operation is optimized for AVX2 technology for pixels of types: SSE2: UINT8, SINT16.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SmoothImage_Mean_Mask.

See Also

- SmoothImage_Gauss_Mask – Smooths an image using a predefined gaussian kernel.
- SmoothImage_Mean – Smooths an image by averaging pixels within a rectangular kernel.

SmoothImage_Median

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the median of pixels within a kernel.

Applications: Edge-preserving noise removal (but slow).

Syntax

```
void avl::SmoothImage_Median
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 avl::SmoothImageMedianKernel::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels being written
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels being read
→	inKernel	SmoothImageMedianKernel::Type			
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Hints

- Define the kernel size by setting the **inRadiusX** and **inRadiusY** inputs.
- For small kernels consider switching to SmoothImage_Median_Mask to achieve higher performance.

Examples

SmoothImage_Median *performed on a sample image with* ***inRadiusX*** *= 4,* ***inRadiusY*** *= Nil.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported kernel in SmoothImage_Median.
DomainError	Not supported pixel format in SmoothImage_Median.
DomainError	Region exceeds an input image in SmoothImage_Median.
DomainError	Source roi exceeds an input image in SmoothImage_Median.
DomainError	Not supported inImage pixel format in SmoothImage_Median. Supported formats: UInt8.

SmoothImage_Median_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the median of pixels within a 3x3 rectangular kernel (faster).

Syntax

```
void avl::SmoothImage_Median_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Examples

SmoothImage_Median_Mask *performed on a sample image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SmoothImage_Median_Mask.
DomainError	Not supported inImage pixel format in SmoothImage_Median_Mask. Supported formats: UInt8.

SmoothImage_Middle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with the average of maximum and minimum calculated within a kernel.

Applications: Useful for calculating per-pixel threshold values for image binarization.

Syntax

```
void avl::SmoothImage_Middle
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be read
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for technology.

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	inBorderColor is relevant only when inSourceRoi is set to Auto (NIL) in SmoothImage_Middle.
DomainError	Not supported kernel on input in SmoothImage_Middle.
DomainError	Region exceeds an input image in SmoothImage_Middle.

SmoothImage_Quantile

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Replaces each pixel with a quantile of pixels within a kernel.

Applications: Edge-preserving noise removal (but slow).

Syntax

```
void avl::SmoothImage_Quantile
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 float inQuantile,
 avl::SmoothImageMedianKernel::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels being written
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels being read
→	inQuantile	float	0.0 – 1.0	0.8f	The quantile to be calculated for a neighbourhood of each pixel
→	inKernel	SmoothImageMedianKernel::Type			
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported kernel in SmoothImage_Quantile.
DomainError	Not supported pixel format in SmoothImage_Quantile.
DomainError	Region exceeds an input image in SmoothImage_Quantile.
DomainError	Source roi exceeds an input image in SmoothImage_Quantile.
DomainError	Not supported inImage pixel format in SmoothImage_Quantile. Supported formats: UInt8.

SmoothRegion_Mean

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Smooths an region by averaging pixels within a rectangular kernel.

Applications: Usually used for computing features related to local image "windows". Can be also used for noise removal, but Gauss is superior here.

Syntax

```
void avl::SmoothRegion_Mean
(
 const avl::Region& inRegion,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

StandardDeviationImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates image of pixels' local standard deviations.

Syntax

```
void avl::StandardDeviationImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 const int inKernelRadius,
 avl::Image& outStdDevImage
)
```

Parameters

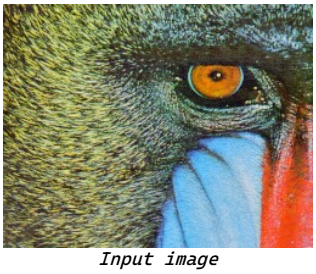
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image.
→	inRoi	Optional<const Region&>		NIL	Region of Interest.
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be read
→	inKernelRadius	const int	1 - 40	4	Radius of square kernel (width and height are 2r+1).
←	outStdDevImage	Image&			Resulting image.

Requirements

For input **inImage** only pixel formats are supported: uint8, int8, uint16, int16, real.

Read more about pixel formats in Image documentation.

Examples



Input image

Output image (with additional postprocessing: normalization)

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in StandardDeviationImage.
DomainError	Not supported inImage pixel format in StandardDeviationImage. Supported formats: UInt8, Int8, UInt16, Int16, Real.

TopHatImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological white top hat operation on a image using a predefined kernel.

Syntax

```
void avl::TopHatImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Image& outImage,
 avl::Region& diagKernel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>		NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>		NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outImage	Image&			Output image
🔍	diagKernel	Region&			Kernel shape

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outImage**

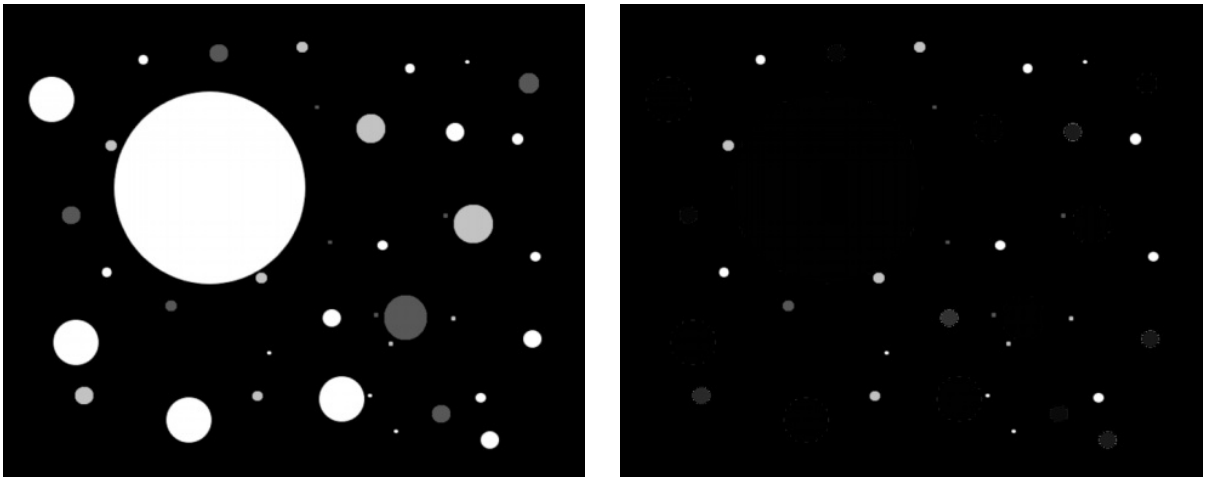
Read more about In-place Computation.

Description

Extracts from image small objects that are brighter than surroundings.

Is performed by running consecutively two filters. OpenImage to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



*Top Hat used to remove bigger objects. Used parameters **inKernel**=Ellipse and **inRadiusX**=6. Source image on the left and result on the right.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in TopHatImage.

TopHatImage_AnyKernel

Also in **AVL Lite**

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological white top hat operation on a image using an arbitrary kernel.

Syntax

```
void avl::TopHatImage_AnyKernel
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inSourceRoi	Optional<const Region&>	NIL	Range of inImage pixels to be considered in computations
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	const Region&		Kernel shape
→	inKernelAnchor	Optional<const Location&>	NIL	A location within inKernel, defining its center
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

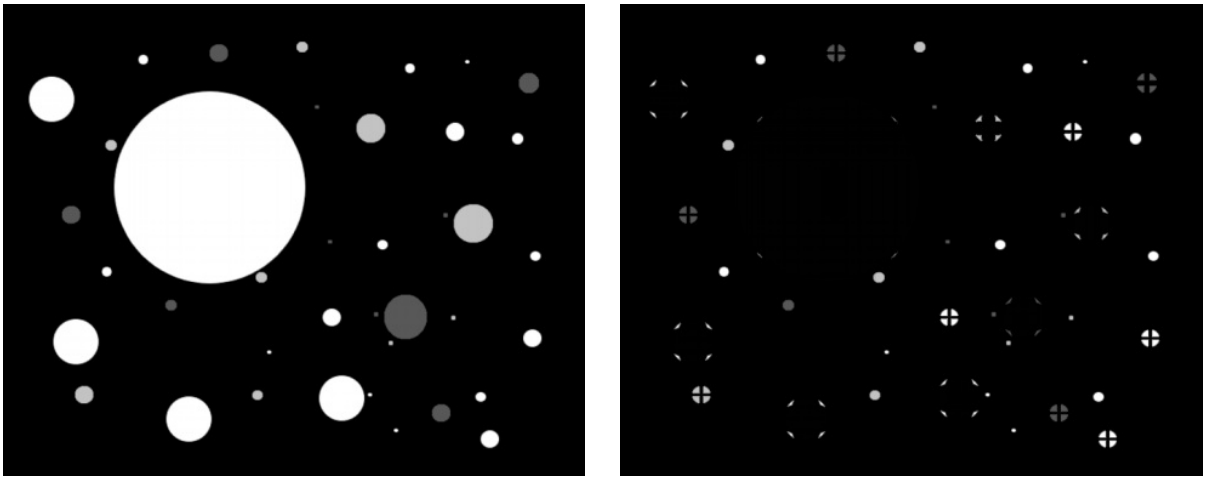
Read more about In-place Computation.

Description

Extracts from image small objects that are brighter than surroundings. Uses user-defined kernel.

Is performed by running consecutively two filters. OpenImage_AnyKernel to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



Top Hat used to remove bigger objects. Source image on the left and result on the right.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in TopHatImage_AnyKernel.

TopHatImage_Mask

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Performs a morphological white top hat operation on a image using a predefined mask.

Syntax

```
void avl::TopHatImage_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::MorphologyKernel::Type inKernel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of outImage pixels to be computed
→	inBorderColor	Optional<Pixel>	NIL	Color of the imaginary pixels outside the image boundaries
→	inKernel	MorphologyKernel::Type		Kernel shape
←	outImage	Image&		Output image

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inImage** and **outImage**

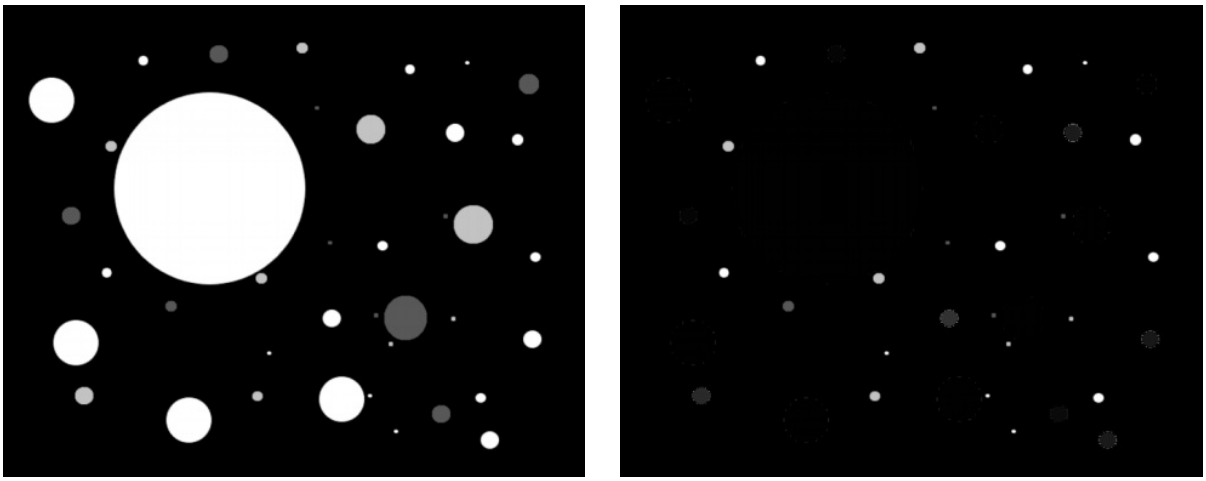
Read more about In-place Computation.

Description

Extracts from image small objects that are brighter than surroundings. Uses predefined mask.

Is performed by running consecutively two filters. OpenImage_Mask to get the image without small objects and SubtractFromImage to remove everything but them.

Examples



Top Hat used to remove bigger objects. Used parameters ***inKernel****=Box5x5. Source image on the left and result on the right.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation is optimized for NEON technology for pixels of types: all formats (when inSourceRoi = NIL and inBorderColor = NIL).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in TopHatImage_Mask.

BottomHatRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological black top hat (bottom hat) operation on a region using a predefined kernel.

Syntax

```
void avl::BottomHatRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

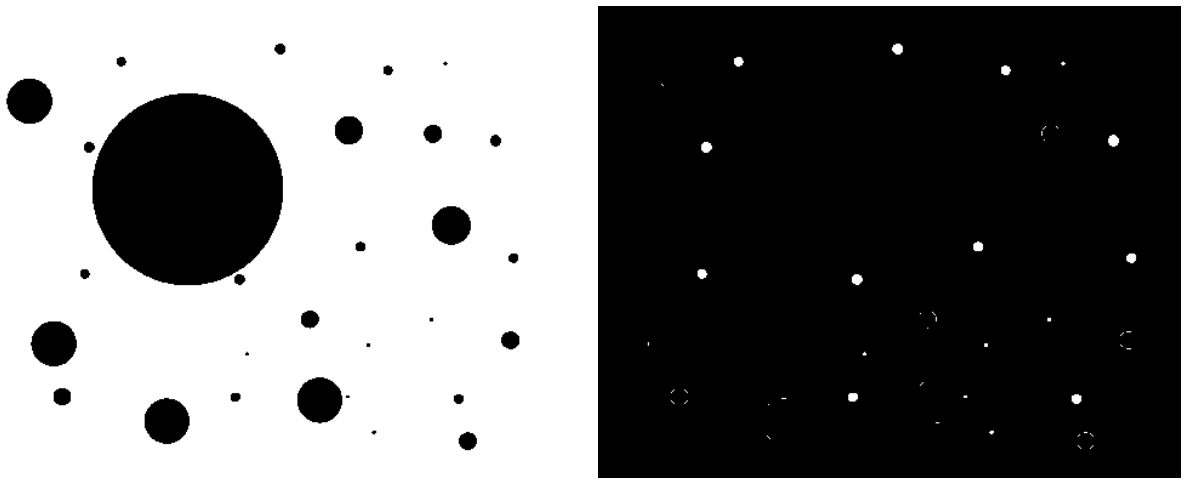
	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outRegion	Region&			Output region

Description

Extracts small parts which do not belong to region. Uses predefined kernels.

Is performed by running consecutively two filters. CloseRegion to remove small holes from region and RegionDifference to remove rest of the region.

Examples



*Top Hat used to remove bigger parts of which do not belong to region. Used parameters **inKernel**=Ellipse and **inRadiusX**=5. Region marked white. Source image on the left and result on the right.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in BottomHatRegion.

BottomHatRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological black top hat (bottom hat) operation on a region using an arbitrary kernel.

Syntax

```
void avl::BottomHatRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 avl::Region& outRegion
)
```

Parameters

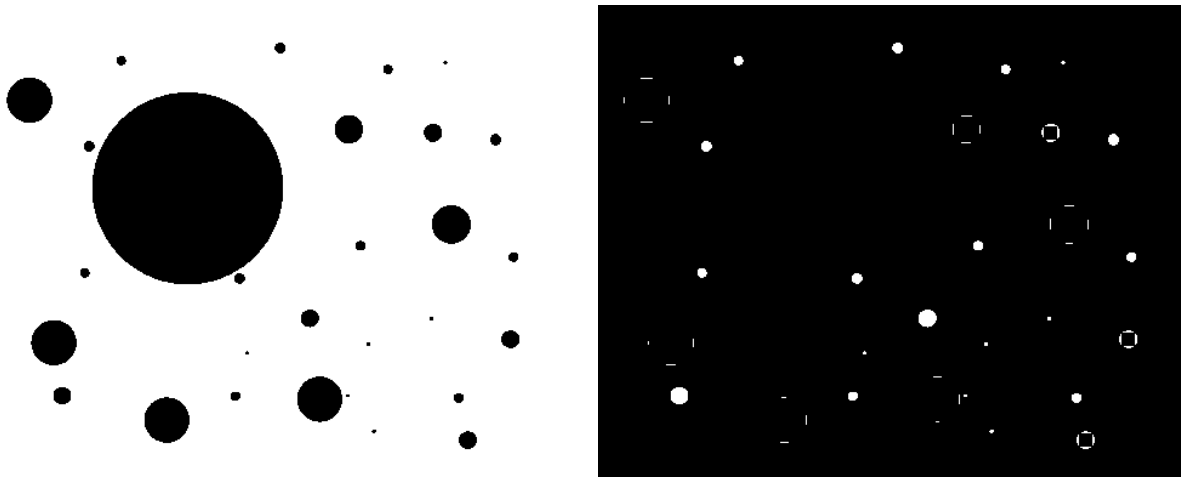
	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inKernel	const Region&		Kernel shape (any)
←	outRegion	Region&		Output region

Description

Extracts small parts which do not belong to region. Uses user-defined kernels.

Is performed by running consecutively two filters. CloseRegion to remove small holes from region and RegionDifference to remove rest of the region.

Examples



Top Hat used to remove bigger parts of which do not belong to region. Region marked white. Source image on the left and result on the right.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in BottomHatRegion_AnyKernel.

CloseRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological closing on a region using selected predefined kernel.

Applications: Filling-in small gaps in a region without making it thicker.

Syntax

```
void avl::CloseRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outRegion	Region&			Output region

Description

The operation performs a morphological closing, which is a tool used for filling gaps in a region. The operation is a convolution of two basic morphological operations:

- Firstly, the input region is dilated using DilateRegion operation.
- Then, the resulting region is eroded using ErodeRegion operation.

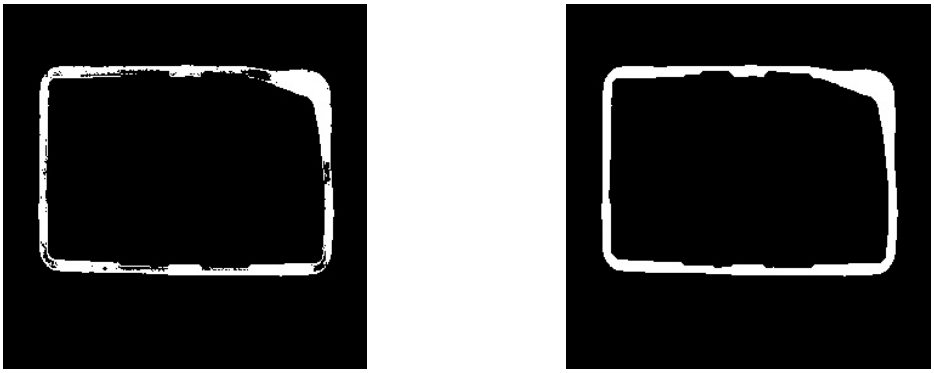
During the dilation gaps that are small enough are actually closed, while further erosion assures that the width of region limbs is preserved.

Both of the component operations are conducted using the same **inKernel**, **inRadiusX** and **inRadiusY** parameters.

Hints

- Increase **inRadiusX** to fill-in bigger gaps in the region.
- Change **inKernel** to Ellipse to make the filter work equally strongly in each direction (execution will be slower).

Examples



*CloseRegion run with **inKernel** = Ellipse of dimensions **inRadiusX** = 5, **inRadiusY** = 5.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in CloseRegion.

See Also

CloseRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological closing on a region using an arbitrary kernel.

Applications: Filling-in gaps of a particular shape without making the region thicker.

Syntax

```
void avl::CloseRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 avl::Region& outRegion
)
```

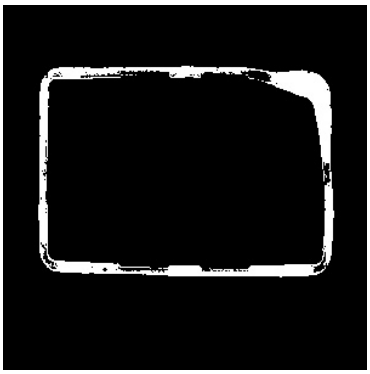
Parameters

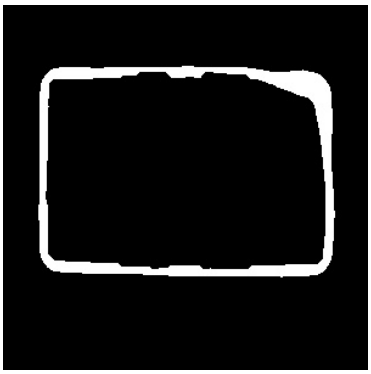
	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
➡	inKernel	const Region&		Kernel shape (any)
⬅	outRegion	Region&		Output region

Description

The operation is a cousin of the CloseRegion filter, yet it uses any proper region selected by user as a structuring element. The center of a kernel is assumed to be at location (width/2,height/2). Refer to the CloseRegion article for further information regarding the morphological closing itself.

Examples





Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in CloseRegion_AnyKernel.

See Also

- CloseRegion – Performs a morphological closing on a region using selected predefined kernel.

DemarcateRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits common pixels of the input regions among these regions.

Applications: Use this filter to make sure that the regions of an array do not intersect.

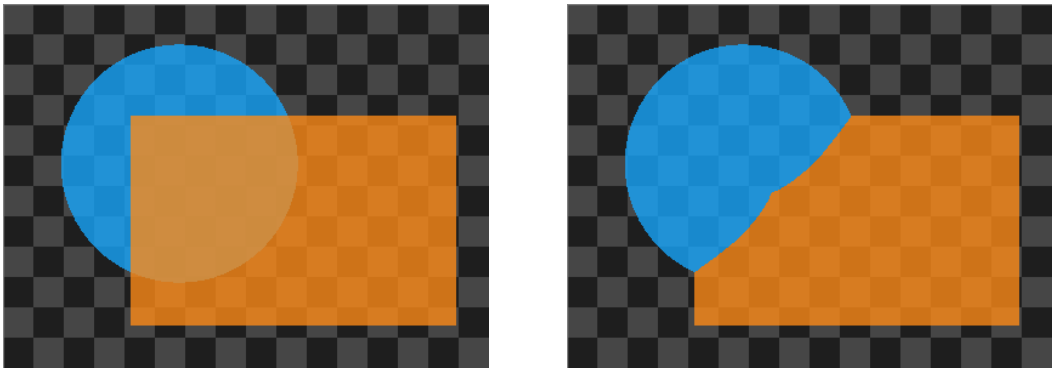
Syntax

```
void avl::DemarcateRegions
(
 const atl::Array<avl::Region>& inRegions,
 atl::Optional<avl::Metric::Type> inMetric,
 atl::Array<avl::Region>& outRegions
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		
→	inMetric	Optional<Metric::Type>	NIL	Metric used for deciding which region owns a pixel; if set to NIL, region with lowest index in the input array is chosen
←	outRegions	Array<Region>&		

Examples



*DemarcateRegions performed with **inMetric** = Euclidean.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Dimensions of two or more regions differ in DemarcateRegions.

DilateRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological dilation on a region using a predefined kernel.

Applications: Making the region thicker or filling-in small holes within it.

Syntax

```
void avl::DilateRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inRegion	const Region&			Input region
➡	inKernel	KernelShape::Type			Kernel shape (predefined)
➡	inRadiusX	int	0 - ∞	1	Nearly half of the kernel's width (2*R+1)
➡	inRadiusY	Optional<int>	0 - ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
⬅	outRegion	Region&			Output region

Description

The operation performs a morphological dilation, which is a basic tool used for region expansion. Similarly to other region morphology operations, dilation is conducted using a shape called kernel (or structuring element). The kernel is repeatedly centered at each location within the dimensions of the input region. Then, pixel location **L** is added to the resulting region if and only if at least one of the input region pixels lies inside the kernel centered at this (**L**) location.

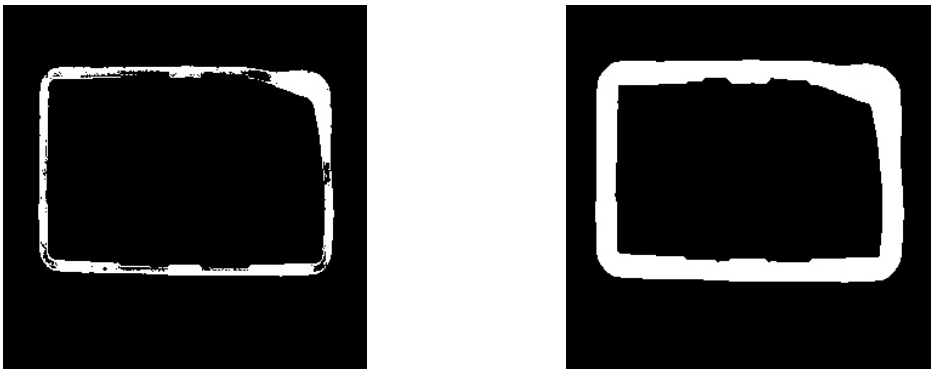
The input parameter **inKernel** allows to choose the shape of a kernel, while parameters **inRadiusX**, **inRadiusY** allow to determine its dimensions. For instance:

- **inKernel** = Ellipse together with **inRadiusX** = **inRadiusY** results in expansion performed equally in all directions.
- Setting **inRadiusX** to higher value than **inRadiusY** results in expansion performed more significantly along horizontal axis.

Hints

- Increase **inRadiusX** to make the output region thicker.
- Change **inKernel** to Ellipse to make the filter work equally strongly in each direction (execution will be slower).

Examples



*DilateRegion run with **inKernel** = Ellipse of dimensions **inRadiusX** = 5, **inRadiusY** = 5.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in DilateRegion.

See Also

- CloseRegion – Performs a morphological closing on a region using selected predefined kernel.

- ErodeRegion – Performs a morphological erosion on a region using a predefined kernel.

DilateRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological dilation on a region using an arbitrary kernel.

Applications: Making the region thicker in a non-symmetrical way or filling-in gaps of a particular shape.

Syntax

```
void avl::DilateRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Region& outRegion
)
```

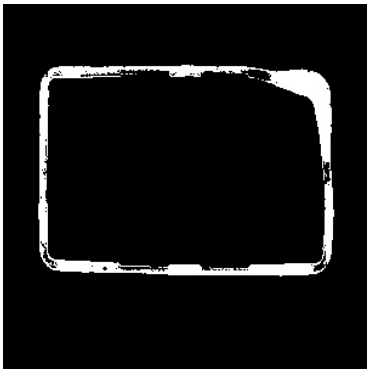
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inKernel	const Region&		Kernel shape (any)
→	inKernelAnchor	Optional<const Location&>	NIL	Location within inKernel, defining its center
←	outRegion	Region&		Output region

Description

The operation is a cousin of the DilateRegion filter, yet it uses any proper region selected by user as a structuring element. The center of a kernel is assumed to be at location (width/2,height/2). Refer to the DilateRegion article for further information regarding the morphological dilation itself.

Examples



Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in DilateRegion_AnyKernel.

See Also

- DilateRegion – Performs a morphological dilation on a region using a predefined kernel.

ErodeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological erosion on a region using a predefined kernel.

Applications: Making the region thinner or removing small parts.

Syntax

```
void avl::ErodeRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outRegion	Region&			Output region

Description

The operation performs a morphological erosion, which is a basic tool used for region shrinking. Similarly to other region morphology operations, erosion is conducted using a shape called kernel (or structuring element). The kernel is repeatedly centered at each location within the dimensions of the input region. Then, pixel location **L** is added to the resulting region if and only if all of the input region pixels lies inside the kernel centered at this (**L**) location.

The input parameter **inKernel** allows to choose the shape of a kernel, while parameters **inRadiusX**, **inRadiusY** allow to determine its dimensions. For instance:

- **inKernel** = Ellipse together with **inRadiusX** = **inRadiusY** results in shrinking performed equally in all directions.
- Setting **inRadiusX** to higher value than **inRadiusY** results in shrinking performed more significantly along horizontal axis.

Hints

- Increase **inRadiusX** to make the output region thinner.
- Change **inKernel** to Ellipse to make the filter work equally strongly in each direction (execution will be slower).

Examples

*ErodeRegion run with **inKernel** = Ellipse of dimensions **inRadiusX** = 3, **inRadiusY** = 3.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in ErodeRegion.

See Also

- OpenRegion – Performs a morphological opening on a region using a predefined kernel.

- DilateRegion – Performs a morphological dilation on a region using a predefined kernel.

ErodeRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological erosion on a region using an arbitrary kernel.

Applications: Making the region thinner in a non-symmetrical way or removing small parts of a particular shape.

Syntax

```
void avl::ErodeRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 avl::Region& outRegion
)
```

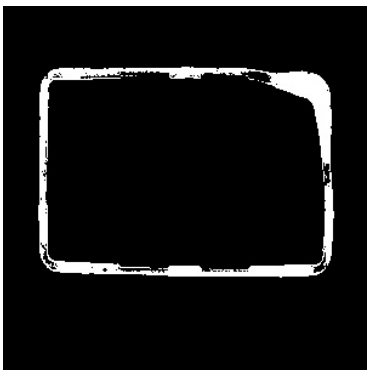
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inKernel	const Region&		Kernel shape (any)
→	inKernelAnchor	Optional<const Location&>	NIL	Location within inKernel, defining its center
←	outRegion	Region&		Output region

Description

The operation is a cousin of the ErodeRegion filter, yet it uses any proper region selected by user as a structuring element. The center of a kernel is assumed to be at location (width/2,height/2). Refer to the ErodeRegion article for further information regarding the morphological erosion itself.

Examples



Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in ErodeRegion_AnyKernel.

See Also

- ErodeRegion – Performs a morphological erosion on a region using a predefined kernel.

ErodeRegion_Threshold

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Erodes a region with inThresholdValue pixels of inKernel.

Syntax

```
void avl::ErodeRegion_Threshold
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 atl::Optional<const avl::Location&> inKernelAnchor,
 const int inThresholdValue,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inKernel	const Region&			
→	inKernelAnchor	Optional<const Location&>		NIL	
→	inThresholdValue	const int	0 – ∞		
←	outRegion	Region&			Output region

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in ErodeRegion_Threshold.

ExpandRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits pixels of the input regions and their complement among these regions.

Applications: Use this filter to make sure that every pixel belongs to a region.

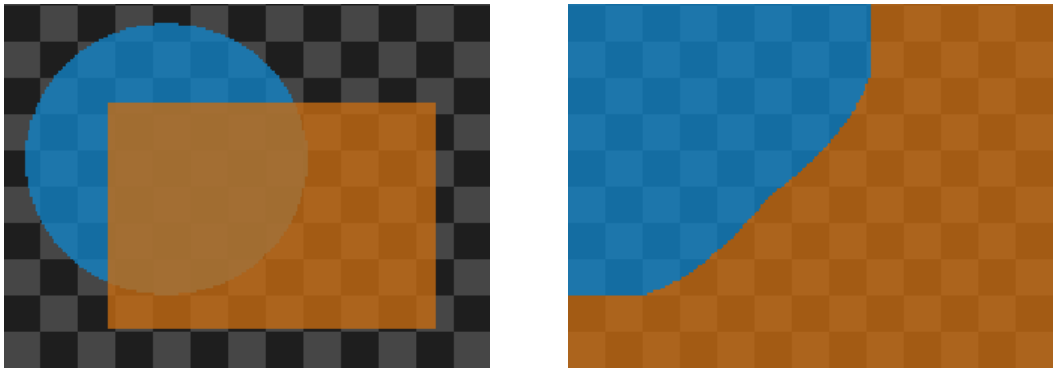
Syntax

```
void avl::ExpandRegions
(
 const atl::Array<avl::Region>& inRegions,
 atl::Optional<avl::Metric::Type> inMetric,
 atl::Array<avl::Region>& outRegions
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		
→	inMetric	Optional<Metric::Type>	NIL	Metric used for deciding which region receives a pixel; if set to NIL, Taxi metric is used after demarcating with NIL metric
←	outRegions	Array<Region>&		

Examples



*ExpandRegions performed with **inMetric** = Taxi.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Dimensions of two or more regions differ in ExpandRegions.
DomainError	Input and output arrays are not distinct in ExpandRegions.

OpenRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological opening on a region using a predefined kernel.

Applications: Removing small parts from a region without making it thinner.

Syntax

```
void avl::OpenRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inRegion	const Region&			Input region
➡	inKernel	KernelShape::Type			Kernel shape (predefined)
➡	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
➡	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
⬅	outRegion	Region&			Output region

Description

The operation performs a morphological opening, which is a tool used for removing thin parts from a region. The operation is a convolution of two basic morphological operations:

- Firstly, the input region is eroded using ErodeRegion operation.
- Then, the resulting region is dilated using DilateRegion operation.

During the erosion thin parts of a region are eliminated, while further dilation assures that the width of region limbs is preserved.

Both of the component operations are conducted using the same **inKernel**, **inRadiusX** and **inRadiusY** parameters.

Hints

- Increase **inRadiusX** to remove more small parts from the region.
- Change **inKernel** to Ellipse to make the filter work equally strongly in each direction (execution will be slower).

Examples

*OpenRegion run with **inKernel** = Ellipse of dimensions **inRadiusX** = 3, **inRadiusY** = 3.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in OpenRegion.

See Also

- ErodeRegion – Performs a morphological erosion on a region using a predefined kernel.
- OpenRegion_AnyKernel – Performs a morphological opening on a region using an arbitrary kernel.
- CloseRegion – Performs a morphological closing on a region using selected predefined kernel.

OpenRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological opening on a region using an arbitrary kernel.

Applications: Removing small parts of a particular shape without making the region thinner.

Syntax

```
void avl::OpenRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 avl::Region& outRegion
)
```

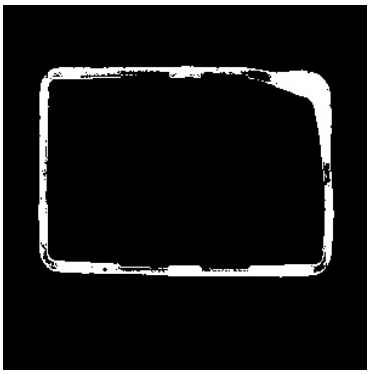
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inKernel	const Region&		Kernel shape (any)
←	outRegion	Region&		Output region

Description

The operation is a cousin of the OpenRegion filter, yet it uses any proper region selected by user as a structuring element. The center of a kernel is assumed to be at location (width/2,height/2). Refer to the OpenRegion article for further information regarding the morphological opening itself.

Examples



Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in OpenRegion_AnyKernel.

See Also

- OpenRegion – Performs a morphological opening on a region using a predefined kernel.

PruneRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Removes one pixel wide branches from a region.

Syntax

```
void avl::PruneRegion
(
 const avl::Region& inRegion,
 const int inMaxLength,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inMaxLength	const int	0 – ∞	3	Maximal length of a branch of the input region to be pruned
←	outRegion	Region&			Output region

Description

The operation removes all branches with length at most **inMaxLength** from the input region. The branches being removed have to be at most one pixel wide, so the filter should be invoked on thinned regions such as the results of SkeletonizeRegion operation only.

Examples

PruneRegion *run on a sample one pixel wide region with* ***inMaxLength*** *= 58.*

See Also

- SkeletonizeRegion – Thins a region to its skeleton.

RegionHitAndMissTransform

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a hit-and-miss transformation on a region using arbitrary kernels.

Syntax

```
void avl::RegionHitAndMissTransform
(
 const avl::Region& inRegion,
 const avl::Region& inHitKernel,
 atl::Optional<const avl::Location&> inHitKernelAnchor,
 const avl::Region& inMissKernel,
 atl::Optional<const avl::Location&> inMissKernelAnchor,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
➡	inHitKernel	const Region&		The kernel of pixels that should be present
➡	inHitKernelAnchor	Optional<const Location&>	NIL	Location withing inHitKernel, defining its center
➡	inMissKernel	const Region&		The kernel of pixels that should be missing
➡	inMissKernelAnchor	Optional<const Location&>	NIL	Location withing inMissKernel, defining its center
⬅	outRegion	Region&		Output region

Description

The operation performs a hit-and-miss transformation. Similarly to other region morphology operations, hit-and-miss is conducted using a shape called kernel (or structuring element). In this particular case, there are two kernels: **inHitKernel** and **inMissKernel**. Both of them are repeatedly centered at each location within the dimensions of the input region. Then, pixel location **L** is added to the resulting region if and only if all of the **inHitKernel** pixels centered at **L** lie inside and all of the **inMissKernel** pixels centered at **L** lie outside the input region.

Examples

RegionHitAndMissTransform *run with kernels* $\begin{bmatrix} 1 & x & x \\ 1 & 0 & x \\ 1 & x & x \end{bmatrix}$ *where* `1`*'s represent pixels from* ***inHitKernel***, `0`*'s from* ***inMissKernel*** *and* `x`*'s the other ones.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Hit kernel empty in RegionHitAndMissTransform.
DomainError	Inconsistent region dimensions in RegionHitAndMissTransform.
DomainError	Miss kernel empty in RegionHitAndMissTransform.

See Also

- ErodeRegion_AnyKernel – Performs a morphological erosion on a region using an arbitrary kernel.
- DilateRegion_AnyKernel – Performs a morphological dilation on a region using an arbitrary kernel.

SkeletonizeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thins a region to its skeleton.

Syntax

```
void avl::SkeletonizeRegion
(
 const avl::Region& inRegion,
 avl::RegionSkeletonMethod::Type inRegionSkeletonMethod,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inRegionSkeletonMethod	RegionSkeletonMethod::Type	TwelveConnected	
←	outRegion	Region&		Output region

Description

The operation performs skeletonization presenting result as a region.

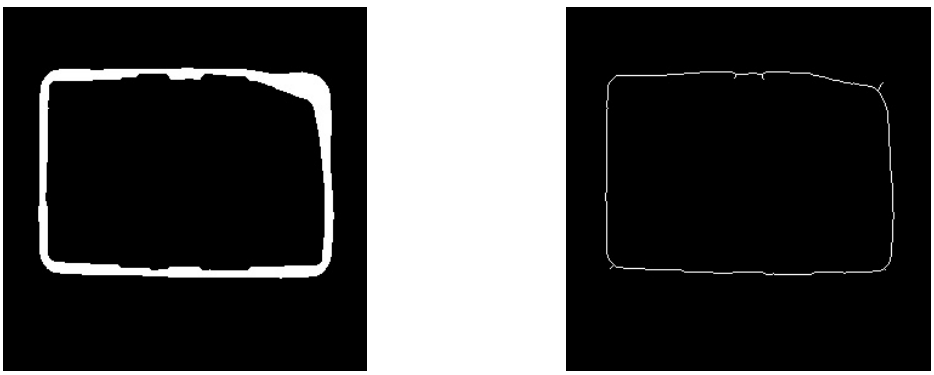
Skeleton of a region is a connected set of medial axis of its limbs. It is a useful tool when one is interested only in general structure of a shape and wants to disregard width of its limbs. Two methods are available, depending on the value of **inRegionSkeletonMethod** being chosen:

- **EightConnected**: the input region is thinned as long as the thinning procedure affects it; the structuring elements come from the well known Golay alphabet
- **TwelveConnected**: the input region is thinned also, but the structuring elements being used are slightly larger than in previous method (they consider 12-neighborhood of the given pixel instead of 8-neighborhood). The method comes from the paper of U. Eckhardt and G. Maderlechner "Invariant thinning"

The second method is slower than the first one, but its results look in most cases much better than the first one's results.

This filter is a cousin of RegionMedialAxis which represents the results as an array of paths instead of a region.

Examples



__SkeletonizeRegion__ run on a sample region with __inRegionSkeletonMethod__ = __TwelveConnected__.

See Also

- RegionMedialAxis – Computes an array of paths corresponding to the skeleton of the input region.

ThickenRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological thickening on a region using predefined kernels.

Syntax

```
void avl::ThickenRegion
(
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

The operation performs a morphological thickening. Similarly to other region morphology operations, thickening is conducted using a shape called kernel (or structuring element). There are two kernels: hit kernel and miss kernel, which are passed as parameters to RegionHitAndMissTransform. This operation's result is then added to the input region giving the output region. The filter uses internally predefined kernels, which are dual to those from ThinRegion filter.

See Also

- ThinRegion – Performs a morphological thinning on a region using predefined kernels.
- RegionHitAndMissTransform – Performs a hit-and-miss transformation on a region using arbitrary kernels.
- DilateRegion_AnyKernel – Performs a morphological dilation on a region using an arbitrary kernel.

ThinRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological thinning on a region using predefined kernels.

Syntax

```
void avl::ThinRegion
(
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

The operation performs a morphological thinning. Similarly to other region morphology operations, thinning is conducted using a shape called kernel (or structuring element). There are two kernels: hit kernel and miss kernel, which are passed as parameters to RegionHitAndMissTransform. This operation's result is then subtracted from the input region giving the output region. The filter uses internally predefined kernels, which are the same as in SkeletonizeRegion filter.

See Also

- SkeletonizeRegion – Thins a region to its skeleton.
- ThickenRegion – Performs a morphological thickening on a region using predefined kernels.
- RegionHitAndMissTransform – Performs a hit-and-miss transformation on a region using arbitrary kernels.
- ErodeRegion_AnyKernel – Performs a morphological erosion on a region using an arbitrary kernel.

ThresholdSmoothedRegion_Mean

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns region of pixels witch collect minAmount of pixels in rectangle in input region.

Syntax

```
void avl::ThresholdSmoothedRegion_Mean
(
 const avl::Region& inRegion,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 float inMinCount,
 int& outMinAmount,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inRadiusX	int			Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>		NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
→	inMinCount	float	0.0 - 1.0		Minimal part of pixels in rectangle to be in region
←	outMinAmount	int&			
←	outRegion	Region&			Output region

TopHatRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological white top hat operation on a region using a predefined kernel.

Syntax

```
void avl::TopHatRegion
(
 const avl::Region& inRegion,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Region& outRegion
)
```

Parameters

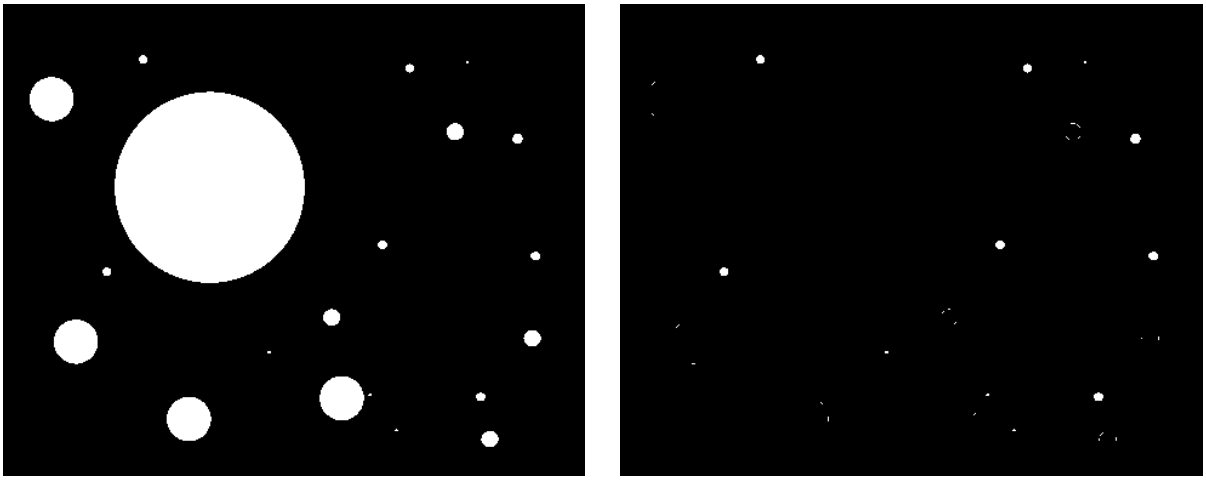
	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inKernel	KernelShape::Type			Kernel shape (predefined)
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outRegion	Region&			Output region

Description

Extracts from region small parts. Uses predefined kernels.

Is performed by running consecutively two filters. OpenRegion to remove small parts from region and RegionDifference to remove rest of the region.

Examples



*Top Hat used to remove bigger parts of region. Used parameters **inKernel**=Ellipse and **inRadiusX**=5. Region marked white. Source image on the left and result on the right.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported kernel in TopHatRegion.

TopHatRegion_AnyKernel

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological white top hat operation on a region using an arbitrary kernel.

Syntax

```
void avl::TopHatRegion_AnyKernel
(
 const avl::Region& inRegion,
 const avl::Region& inKernel,
 avl::Region& outRegion
)
```

Parameters

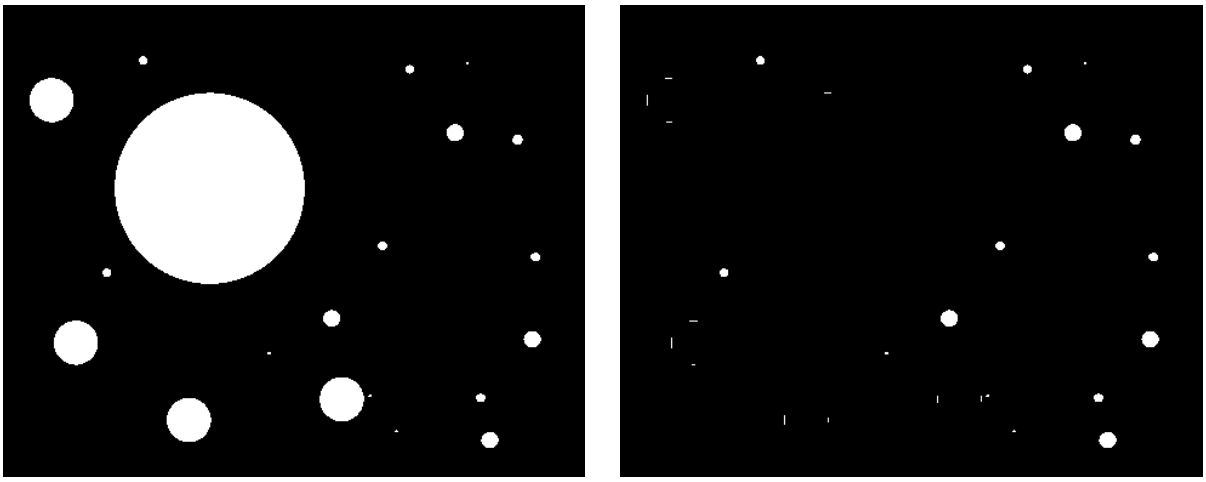
	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inKernel	const Region&		Kernel shape (any)
←	outRegion	Region&		Output region

Description

Extracts from region small parts. Uses user-defined kernels.

Is performed by running consecutively two filters. OpenRegion to remove small parts from region and RegionDifference to remove rest of the region.

Examples



Top Hat used to remove bigger parts of region. Region marked white. Source image on the left and result on the right.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty kernel on input in TopHatRegion_AnyKernel.

Box3DCenter

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns the center of the input box in 3D.

Syntax

```
void avl::Box3DCenter
(
 const avl::Box3D& inBox3D,
 avl::Point3D& outCenter
)
```

Parameters

	Name	Type	Default	Description
➡	inBox3D	const Box3D&		
⬅	outCenter	Point3D&		

Box3DCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns a characteristic point of a box in 3D.

Syntax

```
void avl::Box3DCharacteristicPoint
(
 const avl::Box3D& inBox3D,
 const avl::Anchor3D& inPoint3DAnchor,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Default	Description
➡	inBox3D	const Box3D&		
➡	inPoint3DAnchor	const Anchor3D&		Selecting one of the 27 characteristic points
⬅	outPoint3D	Point3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid Anchor3D in Box3DCharacteristicPoint.

Box3DSurfaceArea

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns the surface area of the input box in 3D.

Syntax

```
void avl::Box3DSurfaceArea
(
 const avl::Box3D& inBox3D,
 float& outSurfaceArea
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
←	outSurfaceArea	float&		

Box3DVolume

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns the volume of the input box in 3D.

Syntax

```
void avl::Box3DVolume
(
 const avl::Box3D& inBox3D,
 float& outVolume
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D	const Box3D&		
←	outVolume	float&		

Boxes3DBoundingBox3D_OrNil

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the bounding box 3D of given boxes in 3D; returns NIL if the array is empty.

Syntax

```
void avl::Boxes3DBoundingBox3D_OrNil
(
 const atl::Array<avl::Box3D>& inBoxes3D,
 atl::Conditional<avl::Box3D>& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBoxes3D	const Array<Box3D>&		
←	outBoundingBox3D	Conditional<Box3D>&		

BoxesBoundingBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the bounding box 3D of given boxes in 3D.

Syntax

```
void avl::BoxesBoundingBox3D
(
 const atl::Array<avl::Box3D>& inBoxes3D,
 avl::Box3D& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
➡	inBoxes3D	const Array<Box3D>&		
⬅	outBoundingBox3D	Box3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in BoxesBoundingBox3D.

Circle3DArea

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the area of a circle in 3D.

Syntax

```
void avl::Circle3DArea
(
 const avl::Circle3D& inCircle3D,
 float& outArea
)
```

Parameters

	Name	Type	Default	Description
➡	inCircle3D	const Circle3D&		
⬅	outArea	float&		

Circle3DBoundingBox

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the smallest box in 3D containing a circle in 3D.

Syntax

```
void avl::Circle3DBoundingBox
(
 const avl::Circle3D& inCircle3D,
 avl::Box3D& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
←	outBoundingBox3D	Box3D&		

Circle3DPerimeterLength

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the length of a circle in 3D perimeter.

Syntax

```
void avl::Circle3DPerimeterLength
(
 const avl::Circle3D& inCircle3D,
 float& outPerimeterLength
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
←	outPerimeterLength	float&		

Plane3DNormalVector

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the normal vector of a line.

Syntax

```
void avl::Plane3DNormalVector
(
 const avl::Plane3D& inPlane,
 avl::Vector3D& outNormalVector
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
←	outNormalVector	Vector3D&		

Plane3DOrientation

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the orientation of a plane as angles in the range from 0 to 180 between the plane and coordinate planes.

Syntax

```
void avl::Plane3DOrientation
(
 const avl::Plane3D& inPlane,
 float& outAngleXY,
 float& outAngleXZ,
 float& outAngleYZ,
 atl::Optional<avl::Point3D&> outPointOnPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPlane	const Plane3D&		
←	outAngleXY	float&		
←	outAngleXZ	float&		
←	outAngleYZ	float&		
←	outPointOnPlane	Optional<Point3D&>	NIL	Projection of the beginning of the coordinate axes on the input plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPointOnPlane**.

Read more about Optional Outputs.

Points3DMedian

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the geometric median of the input points.

Syntax

```
void avl::Points3DMedian
(
 const atl::Array<avl::Point3D>& inPoints,
 atl::Optional<const atl::Array<float>&> inWeights,
 const int inMaxIterationCount,
 avl::Point3D& outGeometricMedian,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Array<avl::Point3D>& diagApproximationSteps = atl::Dummy<atl::Array<Point3D>>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			Input points
→	inWeights	Optional<const Array<float>&>		NIL	Optional input weights
→	inMaxIterationCount	const int	1 – ∞	10	Maximum number of iterations
←	outGeometricMedian	Point3D&			Geometric median
←	outDistanceSum	Optional<float&>		NIL	Sum of distances from input points to geometric median
🔍	diagApproximationSteps	Array<Point3D>&			Approximate geometric medians calculated during subsequent iterations

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input arrays must be of the same size in Points3DMedian.
DomainError	Input point array is empty in Points3DMedian.

PointsBoundingBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the smallest box in 3D containing an array of points in 3D.

Syntax

```
void avl::PointsBoundingBox3D
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::Box3D& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
←	outBoundingBox3D	Box3D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in PointsBoundingBox3D.

PointsBoundingBox3D_OrNil

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the smallest box in 3D containing an array of points in 3D; returns NIL if the array is empty.

Syntax

```
void avl::PointsBoundingBox3D_OrNil
(
 const atl::Array<avl::Point3D>& inPoints,
 atl::Conditional<avl::Box3D>& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
←	outBoundingBox3D	Conditional<Box3D>&		

PointsMassCenter3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the central point of the input points.

Syntax

```
void avl::PointsMassCenter3D
(
 const atl::Array<avl::Point3D>& inPoints,
 avl::Point3D& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		Input array of points
←	outMassCenter	Point3D&		Central point of input points

Errors

List of possible exceptions:

Error type	Description
DomainError	Input point array is empty in PointsMassCenter3D.

Segment3DBisector

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a plane passing through the center of a segment in 3D at a right angle.

Syntax

```
void avl::Segment3DBisector
(
 const avl::Segment3D& inSegment3D,
 avl::Plane3D& outBisector
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outBisector	Plane3D&		

Segment3DBoundingBox

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the smallest box in 3D containing a segment in 3D.

Syntax

```
void avl::Segment3DBoundingBox
(
 const avl::Segment3D& inSegment3D,
 avl::Box3D& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outBoundingBox3D	Box3D&		

Segment3DCenter

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the center point of a segment in 3D.

Syntax

```
void avl::Segment3DCenter
(
 const avl::Segment3D& inSegment3D,
 avl::Point3D& outCenterPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outCenterPoint	Point3D&		

Segment3DLength

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the length of a segment in 3D.

Syntax

```
void avl::Segment3DLength
(
 const avl::Segment3D& inSegment3D,
 float& outLength
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outLength	float&		

Segment3DLine

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the line in 3D passing through a segment.

Syntax

```
void avl::Segment3DLine
(
 const avl::Segment3D& inSegment3D,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		Input segment in 3D
←	outLine3D	Line3D&		The resulting line

Segment3DVector

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Returns the vector [x2 - x1, y2 - y1, z2 - z1].

Syntax

```
void avl::Segment3DVector
(
 const avl::Segment3D& inSegment3D,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
←	outVector3D	Vector3D&		

Vector3DAzimuth

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the angle between a 3D vector's projection to the XY plane and the X axis measured toward Y axis, as an angle in the range from 0 to 360.

Syntax

```
void avl::Vector3DAzimuth
(
 const avl::Vector3D& inVector3D,
 float& outAzimuth
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
←	outAzimuth	float&		

Vector3DElevation

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the angle between a 3D vector's projection to the XY plane and itself measured toward Z axis, as an angle in the range from -90 to 90.

Syntax

```
void avl::Vector3DElevation
(
 const avl::Vector3D& inVector3D,
 float& outElevation
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
←	outElevation	float&		

Vector3DLength

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the length of a 3D vector.

Syntax

```
void avl::Vector3DLength
(
 const avl::Vector3D& inVector3D,
 float& outLength
)
```

Parameters

	Name	Type	Default	Description
→	inVector3D	const Vector3D&		
←	outLength	float&		

Vectors3DMedian

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the geometric median of the input vectors.

Syntax

```
void avl::Vectors3DMedian
(
 const atl::Array<avl::Vector3D>& inVectors,
 atl::Optional<const atl::Array<float>&> inWeights,
 const int inMaxIterationCount,
 avl::Vector3D& outGeometricMedian,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Array<avl::Vector3D>& diagApproximationSteps = atl::Dummy<atl::Array<Vector3D>>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVectors	const Array<Vector3D>&			Input vectors
→	inWeights	Optional<const Array<float>&>		NIL	Optional input weights
→	inMaxIterationCount	const int	1 – ∞	10	Maximum number of iterations
←	outGeometricMedian	Vector3D&			Geometric median
←	outDistanceSum	Optional<float&>		NIL	Sum of distances from input vectors to geometric median
🔍	diagApproximationSteps	Array<Vector3D>&			Approximate geometric medians calculated during subsequent iterations

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input arrays must be of the same size in Vectors3DMedian.
DomainError	Input vector array is empty in Vectors3DMedian.

59. Geometry 3D Intersections

Table of content:

- BoxIntersection3D
- CirclePlaneIntersection3D
- LineLineIntersection3D
- LinePlaneIntersection3D
- PlanePlaneIntersection3D
- SegmentPlaneIntersection3D

BoxIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the common part of two boxes in 3D.

Syntax

```
void avl::BoxIntersection3D
(
 const avl::Box3D& inBox3D1,
 const avl::Box3D& inBox3D2,
 avl::Box3D& outBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inBox3D1	const Box3D&		
→	inBox3D2	const Box3D&		
←	outBox3D	Box3D&		

CirclePlaneIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes common points of a circle in 3D and a plane.

Syntax

```
void avl::CirclePlaneIntersection3D
(
 const avl::Circle3D& inCircle3D,
 const avl::Plane3D& inPlane,
 atl::Conditional<avl::Point3D>& outIntersectionPoint1,
 atl::Conditional<avl::Point3D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inCircle3D	const Circle3D&		
→	inPlane	const Plane3D&		
←	outIntersectionPoint1	Conditional<Point3D>&		
←	outIntersectionPoint2	Conditional<Point3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in CirclePlaneIntersection3D.
DomainError	Indefinite plane on input in CirclePlaneIntersection3D.

LineLineIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a common point of two lines in 3D.

Syntax

```
void avl::LineLineIntersection3D
(
 const avl::Line3D& inLine1,
 const avl::Line3D& inLine2,
 atl::Conditional<avl::Point3D>& outIntersectionPoint
)
```

Parameters

	Name	Type	Default	Description
→	inLine1	const Line3D&		
→	inLine2	const Line3D&		
←	outIntersectionPoint	Conditional<Point3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LineLineIntersection3D.

LinePlaneIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the intersection point of a line in 3D and a plane.

Syntax

```
void avl::LinePlaneIntersection3D
(
 const avl::Line3D& inLine3D,
 const avl::Plane3D& inPlane,
 atl::Conditional<avl::Point3D>& outIntersectionPoint
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inPlane	const Plane3D&		
←	outIntersectionPoint	Conditional<Point3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LinePlaneIntersection3D.
DomainError	Indefinite plane on input in LinePlaneIntersection3D.

PlanePlaneIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a common line in 3D of two planes.

Syntax

```
void avl::PlanePlaneIntersection3D
(
 const avl::Plane3D& inPlane1,
 const avl::Plane3D& inPlane2,
 atl::Conditional<avl::Line3D>& outIntersectionLine
)
```

Parameters

	Name	Type	Default	Description
→	inPlane1	const Plane3D&		
→	inPlane2	const Plane3D&		
←	outIntersectionLine	Conditional<Line3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in PlanePlaneIntersection3D.

SegmentPlaneIntersection3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes the intersection point of a segment in 3D and a plane.

Syntax

```
void avl::SegmentPlaneIntersection3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Plane3D& inPlane,
 atl::Conditional<avl::Point3D>& outIntersectionPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSegment3D	const Segment3D&		
→	inPlane	const Plane3D&		
←	outIntersectionPoint	Conditional<Point3D>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SegmentPlaneIntersection3D.

60. Image Thresholding

Table of content:

- SelectThresholdValue
- ThresholdImage

- ThresholdToRegion_HSx
- ThresholdToRegion_Relative
- ThresholdToRegion_Relative_DarkBright
- ThresholdToRegion_RGB

SelectThresholdValue

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects best threshold value using the image histogram.

Applications: Usually used before a thresholding filter when the image brightness is variable. Use with care.

Syntax

```
void avl::SelectThresholdValue
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::ThresholdSelectionMethod::Type inMethod,
 float& outThresholdValue,
 atl::Array<float>& diagThresholdRatings,
 atl::Array<float>& diagBackgroundPixelsFraction,
 atl::Array<float>& diagForegroundPixelsFraction
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inMethod	ThresholdSelectionMethod::Type		Method used to select the best threshold
←	outThresholdValue	float&		Best threshold separating background pixels from foreground pixels
🔍	diagThresholdRatings	Array<float>&		Contains ratings gained if that threshold would be chosen
🔍	diagBackgroundPixelsFraction	Array<float>&		Fraction of pixels that are darker than the index value
🔍	diagForegroundPixelsFraction	Array<float>&		Fraction of pixels that are brighter than the index value

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Description

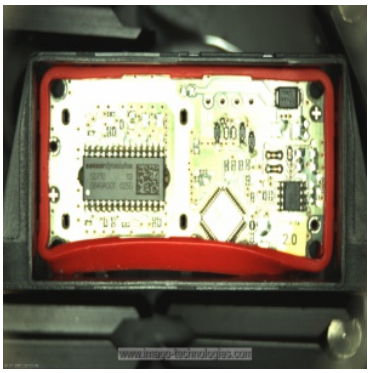
The operation estimates an intensity threshold value that discriminates foreground pixels from background pixels in **inImage**.

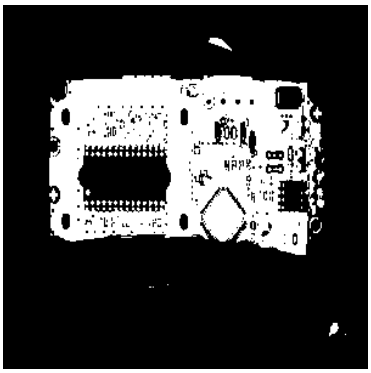
Note that to provide meaningful results it is required that the image in fact consists of foreground and background components that strongly differ in brightness.

Hints

- Choose **inMethod** that works best in your application. None of the methods is perfect, but **ClusteringOtsu** is the most universal one.

Examples





__SelectThresholdValue__ performed on the sample image (on the left) with __inMethod__ = ClusteringKittler yields __outThresholdValue__ = 189.5. Pixels of the input image brighter than 189.5 are presented on the right.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in SelectThresholdValue.
DomainError	Not supported inImage pixel format in SelectThresholdValue. Supported formats: UInt8.

See Also

- ThresholdImage – Transforms each pixel value to maximum or minimum depending on whether they belong to the specified range.

ThresholdImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms each pixel value to maximum or minimum depending on whether they belong to the specified range.

Applications: Image binarization when the illumination is constant and uniform.

Syntax

```
void avl::ThresholdImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 float inFuzziness,
 avl::Image& outMonoImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inMinValue	Optional<float>		128.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue	Optional<float>		NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inFuzziness	float	0.0 – ∞	0.0f	A tolerance for inMin/MaxValue that results in intermediate output values
←	outMonoImage	Image&			

Description

The operation transforms each pixel value to the maximum or minimum level thus creating binary image. The result of the transformation depends on the pixel intensity:

- Pixel values in range (**inMinValue**, **inMaxValue**) are transformed to the maximum level.
- Other pixel values are transformed to the minimum level.

If any of the parameters **inMinValue**, **inMaxValue** is not set, it is assumed to be, accordingly, *-infinity* or *infinity*.

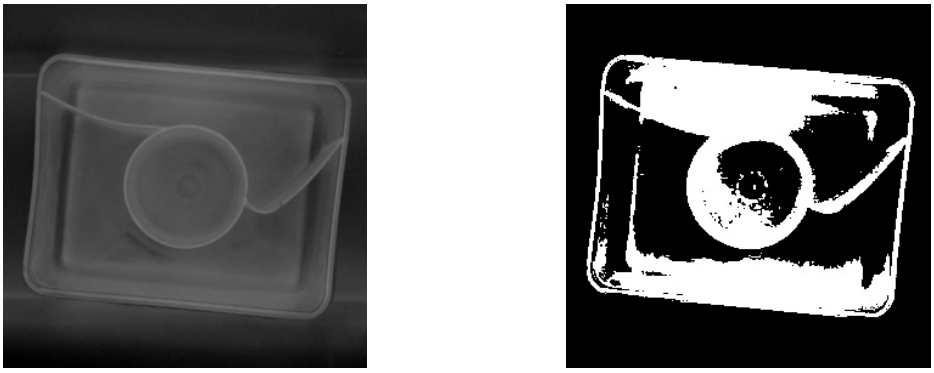
Parameter **inFuzziness** (set to 0 by default) allows to perform fuzzy thresholding which linearly interpolates those pixel values that differ by at most **inFuzziness** from the values **inMinValue**, **inMaxValue**; thus creating smooth transition between minimum and maximum values in the resulting image (see **Remarks** section).

In the multichannel images the operation uses an average of channel values in each pixel, thus the resulting image is always monochromatic.

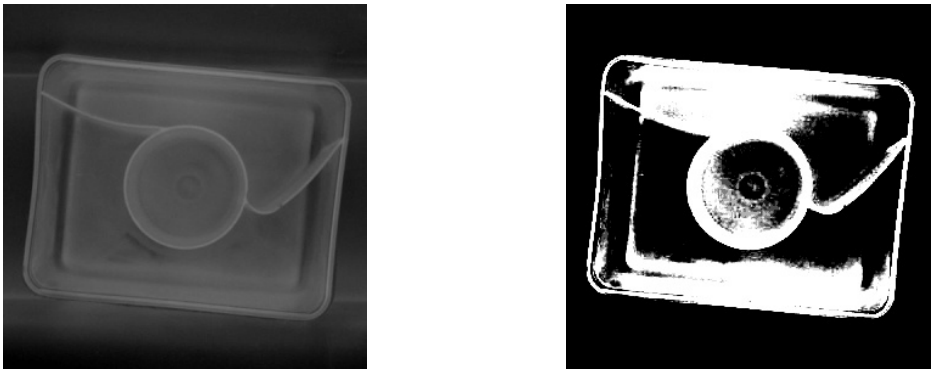
Hints

- Define **inMinValue** to obtain white pixels for bright objects (brighter than the specified value).
- Define **inMaxValue** to obtain white pixels for dark objects (darker than the specified value).
- Use **inFuzziness** to add some smooth transitions between black and white pixels in the result.

Examples



ThresholdImage *performed on the sample image with* ***inMinValue*** *= 80.0,* ***inMaxValue*** *= auto,* ***inFuzziness*** *= 0.0.*



ThresholdImage *performed on the sample image with* ***inMinValue*** *= 80.0,* ***inMaxValue*** *= auto,* ***inFuzziness*** *= 2.5.*

Remarks

When image pixel type is Real, parameter **inFuzziness** has no influence on the output (is ignored). The reason is strictly mathematical. Namely, there does not exist a smooth transition between *-infinity* and *+infinity* values, which are, correspondingly, minimum and maximum levels of pixel brightness.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation is optimized for NEON technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdImage.

See Also

- ThresholdToRegion – Creates a region containing image pixels with values within the specified range.

ThresholdImage_Color

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms each pixel value to maximum or minimum depending on the distance from a given color.

Applications: Color analysis with a given reference color.

Syntax

```
void avl::ThresholdImage_Color
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Pixel& inRgbColor,
 float inChromaAmount,
 float inMaxDifference,
 float inFuzziness,
 avl::Image& outMonoImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inRgbColor	const Pixel&			Color to compare the image to
→	inChromaAmount	float	0.0 – 1.0	0.7f	Proportion of chromatic information in distance computation
→	inMaxDifference	float	0.0 – ∞	5.0f	Maximum difference between image pixel and model color
→	inFuzziness	float	0.0 – ∞	0.0f	A tolerance for computed difference that results in intermediate output values
←	outMonoImage	Image&			

Requirements

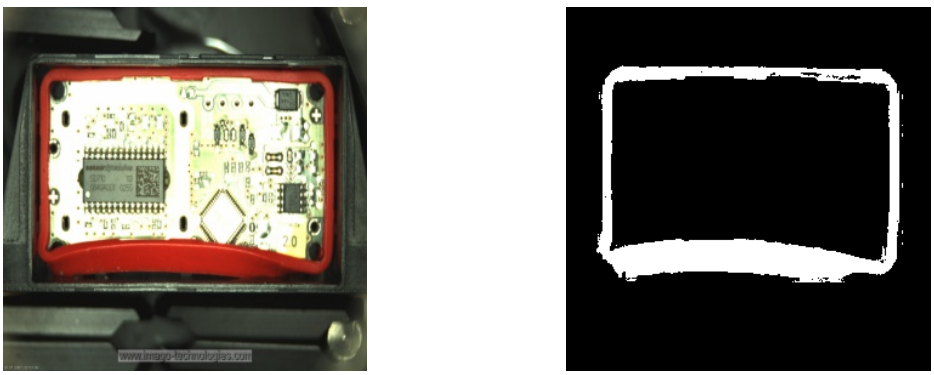
For input **inImage** only pixel formats are supported: 1×uint8, 2×uint8, 3×uint8, 4×uint8.

Read more about pixel formats in Image documentation.

Hints

- Define the reference color by setting the **inRgbColor** input.
- Increase **inChromaAmount** to make the function less sensitive to changes in brightness. Decrease it to make brightness more important.
- Set **inMaxDifference** experimentally to a value that best separates the foreground and background pixels.
- Use **inFuzziness** to add some smooth transitions between black and white pixels in the result.

Examples



ThresholdImage_Color *performed on a sample image with* ***inRgbColor*** *= (192, 34, 22),* ***inChromaAmount*** *= 1.0,* ***inMaxDifference*** *= 48.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation is optimized for NEON technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdImage_Color.
DomainError	Not supported inImage pixel format in ThresholdImage_Color. Supported formats: 1xUInt8, 2xUInt8, 3xUInt8, 4xUInt8.

See Also

- ColorDistanceImage – Compares each pixel with the specified color using chromatic and non-chromatic information.

ThresholdImage_Dynamic

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Thresholds an image relatively to some value calculated in a local rectangular neighbourhood.

Applications: Image binarization when the illumination is uneven.

Syntax

```
void avl::ThresholdImage_Dynamic
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 avl::ThresholdDynamicReferenceMethod::Type inReferenceMethod,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 atl::Optional<float> inMinRelativeValue,
 atl::Optional<float> inMaxRelativeValue,
 float inFuzziness,
 avl::Image& outMonoImage,
 avl::Image& diagBaseImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region in which pixels are written
→	inSourceRoi	Optional<const Region&>		NIL	Region from which pixels are read
→	inReferenceMethod	ThresholdDynamicReferenceMethod::Type		Mean	Specifies how the local threshold value will be calculated (see SmoothImage filter family)
→	inKernel	KernelShape::Type		Box	Kernel shape.
→	inRadiusX	int	0 – 65535	5	Horizontal radius of local neighbourhood.
→	inRadiusY	Optional<int>	0 – 65535	NIL	Vertical radius of local neighbourhood (Auto = inRadiusX)
→	inMinRelativeValue	Optional<float>		0.0f	Minimum relative value of a pixel that is considered foreground (Auto = -INF)
→	inMaxRelativeValue	Optional<float>		NIL	Maximum relative value of a pixel that is considered foreground (Auto = +INF)
→	inFuzziness	float	0.0 – ∞	0.0f	A tolerance for inMin/MaxRelativeValue that results in intermediate output values. Clamped on half of pixel max value (e.g. max fuzziness for uint8 image is 128).
←	outMonoImage	Image&			
🔍	diagBaseImage	Image&			Diagnostic threshold values.

Description

The operation transforms each pixel value to the maximum or minimum level thus creating binary image. The result of the transformation depends on the relative pixel intensity:

- Pixel values that are brighter than local average of the pixel neighbourhood by at least **inMinRelativeValue** and at most **inMaxRelativeValue** are transformed to the maximum level.
- Other pixel values are transformed to the minimum level.

If any of the parameters **inMinRelativeValue**, **inMaxRelativeValue** is not set, it is assumed to be, accordingly, *-infinity* or *infinity*.

Pixel neighbourhood used to compute the local average is a rectangle of dimensions $(2 \cdot \mathbf{inRadiusX} + 1) \times (2 \cdot \mathbf{inRadiusY} + 1)$ centered at the pixel being processed.

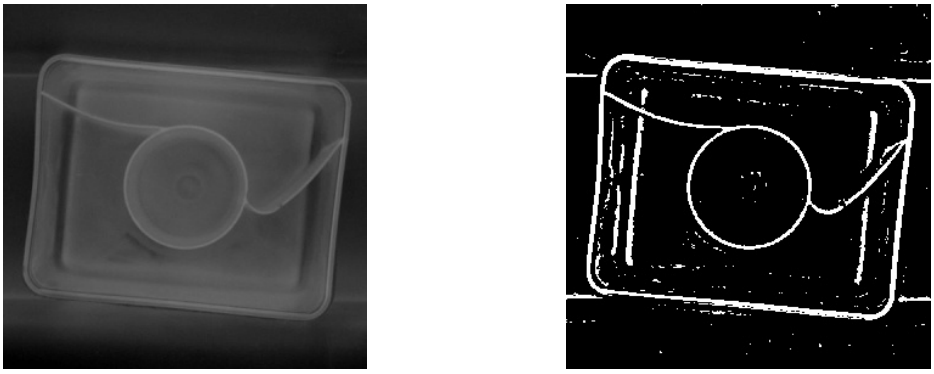
Parameter **inFuzziness** (set to 0 by default) allows to perform fuzzy thresholding which linearly interpolates those pixel values that differ by at most **inFuzziness** from the border intensities; thus creating smooth transition between minimum and maximum values in the resulting image.

In the multichannel images the operation uses an average of channel values in each pixel, thus the resulting image is always monochromatic.

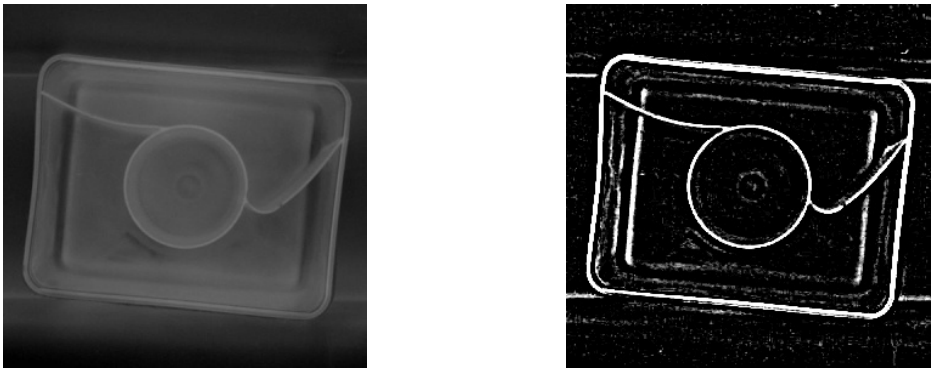
Hints

- Define **inMinRelativeValue** to obtain white pixels for objects which are brighter than the neighborhood.
- Define **inMaxRelativeValue** to obtain white pixels for objects which are darker than the neighborhood.
- Increase **inRadiusX** (and optionally **inRadiusY**) to define a bigger neighborhood.
- Use **inFuzziness** to add some smooth transitions between black and white pixels in the result.

Examples



ThresholdImage_Dynamic *performed on the sample image with* ***inMinRelativeValue*** *= 5.0,* ***inMaxRelativeValue*** *= auto,* ***inFuzziness*** *= 0.0.*



ThresholdImage_Dynamic *performed on the sample image with* ***inMinRelativeValue*** *= 5.0,* ***inMaxRelativeValue*** *= auto,* ***inFuzziness*** *= 10.0.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 1xUINT8.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect fuzziness value in ThresholdImage_Dynamic.
DomainError	Roi exceeds image dimensions in ThresholdImage_Dynamic.
DomainError	Source roi exceeds image dimensions in ThresholdImage_Dynamic.

See Also

- ThresholdToRegion_Dynamic – Thresholds an image relatively to the average pixel value in a local rectangular neighborhood.

ThresholdImage_HSx

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms each pixel value to minimum or maximum depending on whether it belongs to specified region in the HSV, HSL or HSI color space.

Applications: Color analysis.

Syntax

```
void avl::ThresholdImage_HSx
(
 const avl::Image& inRgbImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::HSxColorModel::Type inColorModel,
 int inBeginHue,
 int inEndHue,
 atl::Optional<int> inMinSaturation,
 atl::Optional<int> inMaxSaturation,
 atl::Optional<int> inMinBrightness,
 atl::Optional<int> inMaxBrightness,
 float inFuzziness,
 avl::Image& outMonoImage,
 avl::Image& diagHSxImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRgbImage	const Image&			Input image in the RGB color space
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inColorModel	HSxColorModel::Type			Selected color model
→	inBeginHue	int	0 – 255	0	Lowest acceptable Hue; if higher than inEndHue, then range wrapping is used
→	inEndHue	int	0 – 255	255	Highest acceptable Hue, if lower than inBeginHue, then range wrapping is used
→	inMinSaturation	Optional<int>	0 – 255	128	
→	inMaxSaturation	Optional<int>	0 – 255	NIL	
→	inMinBrightness	Optional<int>	0 – 255	128	Minimum brightness; denotes V, L or I, depending on inColorModel
→	inMaxBrightness	Optional<int>	0 – 255	NIL	Maximum brightness; denotes V, L or I, depending on inColorModel
→	inFuzziness	float	0.0 – ∞		Tolerance for value ranges that results in intermediate output values
←	outMonoImage	Image&			
🔍	diagHSxImage	Image&			Image in HSx color space

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Description

The operation transforms each pixel of three-channel **inRgbImage** to the maximum or minimum level thus creating binary image. The input image is considered to be encoded using RGB color representation. Each of the image pixel is internally converted to HSx (HSV, HSL or HSI) color representation and then examined.

- Pixels meeting all of the following conditions are transformed to the maximum level:
  - Value of the Hue parameter is in cyclic range (**inBeginHue**, **inEndHue**).
  - Value of the Saturation parameter is in range (**inMinSaturation**, **inMaxSaturation**).
  - Value of the Brightness parameter is in range (**inMinBrightness**, **inMaxBrightness**).
- Other pixels are transformed to the minimum level.

If any of the parameters **inMinSaturation**, **inMinBrightness** is not set, it is assumed to be *-infinity*.

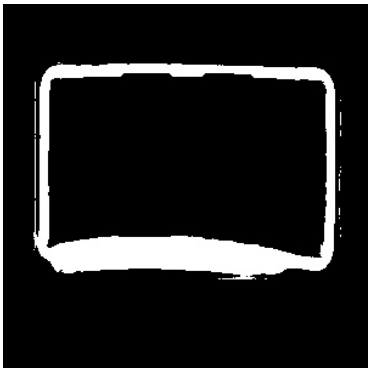
If any of the parameters **inMaxSaturation**, **inMaxBrightness** is not set, it is assumed to be *infinity*.

Parameter **inFuzziness** (set to 0 by default) allows to perform fuzzy thresholding which linearly interpolates those pixel values that differ by at most **inFuzziness** from the border parameter values; thus creating smooth transition between minimum and maximum values in the resulting image.

Hints

- Choose **inColorModel** taking into account accuracy and execution speed (HSV is the fastest, HSI is usually the most accurate).
- Define the range of HSV/HSL/HSI values that best separates the foreground and background pixels. Analyze the results on the **outMonoImage** output.
- Use **inFuzziness** to add some smooth transitions between black and white pixels in the result.

Examples



ThresholdImage_HSx *performed on the sample image with* ***inColorModel*** *= HSV,* ***inBeginHue*** *= 0.0,* ***inEndHue*** *= 10.0,* ***inMinSaturation*** *= 120.0,* ***inMinBrightness*** *= 70.0.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in ThresholdImage_HSx.
DomainError	Region exceeds an input image in ThresholdImage_HSx.
DomainError	Not supported inRgbImage pixel format in ThresholdImage_HSx. Supported formats: 3xUInt8.

See Also

- ThresholdToRegion_HSx – Creates a region containing image pixels which belongs to specified region in HSV, HSL or HSI space.

ThresholdImage_Hysteresis

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thresholds an image with a hysteresis, i.e. with a lower threshold for neighboring pixels.

Syntax

```
void avl::ThresholdImage_Hysteresis
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 float inHysteresis,
 avl::Image& outMonoImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inMinValue	Optional<float>		128.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue	Optional<float>		NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inHysteresis	float	0.0 – ∞	16.0f	Defines how much the threshold criteria are lowered for pixels neighboring with other foreground pixels
←	outMonoImage	Image&			

Description

The operation transforms each pixel value to the maximum or minimum level thus creating binary image. The result of the transformation depends on the pixel intensity:

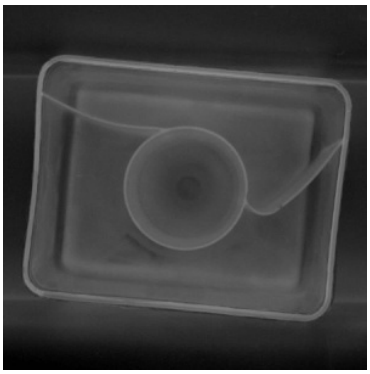
- Pixel values in range [**inMinValue**, **inMaxValue**] are transformed to the maximum level.
- Pixel values lower than **inMinValue**-**inHysteresis** or higher than **inMaxValue**+**inHysteresis** are transformed to the minimum level.
- Pixel values in range [**inMinValue**-**inHysteresis**, **inMinValue**) or in range (**inMaxValue**, **inMaxValue**+**inHysteresis**] are transformed to the maximum if (and only if) in the processed image there is a path of consecutive pixels of value in range [**inMinValue**-**inHysteresis**, **inMaxValue**+**inHysteresis**] that connects the pixel being considered and any pixel with value in range [**inMinValue**, **inMaxValue**].

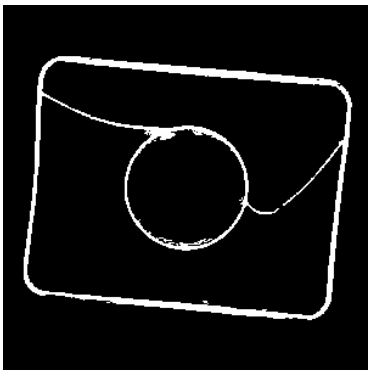
In the multichannel images the operation uses an average of channel values in each pixel, thus the resulting image is always monochromatic.

Hints

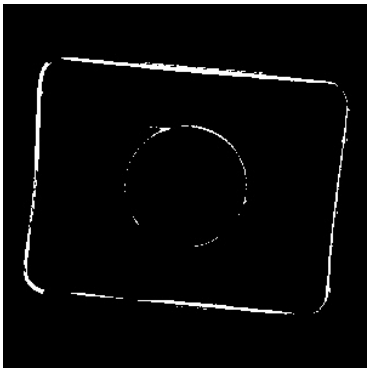
- Define **inMinValue** to extract bright objects (brighter than the specified value).
- Define **inMaxValue** to extract dark objects (darker than the specified value).
- Use **inHysteresis** to allow weaker threshold for pixels neighboring with already extracted ones.

Examples

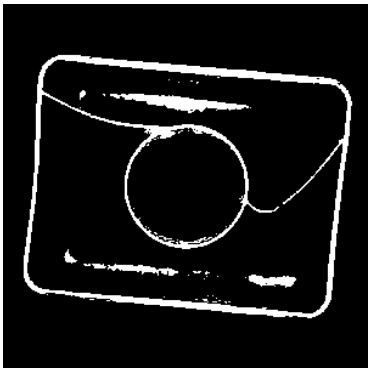




ThresholdImage_Hysteresis *performed on the sample image with* ***inMinValue*** *= 110.0,* ***inMaxValue*** *= Nil,* ***inHysteresis*** *= 15.0.*



Pixels of the sample image brighter than 110.0.



Pixels of the sample image brighter than 95.0.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdImage_Hysteresis.

See Also

- ThresholdToRegion – Creates a region containing image pixels with values within the specified range.

ThresholdImage_Multirange

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms each pixel value to maximum or minimum depending on whether they belong to the specified range.

Applications: Image binarization when the illumination is constant and uniform.

Syntax

```
void avl::ThresholdImage_Multirange
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<float> inMinValue1,
 atl::Optional<float> inMaxValue1,
 atl::Optional<float> inMinValue2,
 atl::Optional<float> inMaxValue2,
 atl::Optional<float> inMinValue3,
 atl::Optional<float> inMaxValue3,
 atl::Optional<float> inMinValue4,
 atl::Optional<float> inMaxValue4,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Region of interest
→	inMinValue1	Optional<float>	1.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue1	Optional<float>	NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inMinValue2	Optional<float>	64.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue2	Optional<float>	NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inMinValue3	Optional<float>	128.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue3	Optional<float>	NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inMinValue4	Optional<float>	192.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue4	Optional<float>	NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
←	outImage	Image&		Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8 (for inFuzziness = 0).

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8 (for inFuzziness = 0) PARALLEL.

ThresholdImage_Relative

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thresholds an image with a different threshold value for each pixel (inBaseImage(x, y) + inValue).

Syntax

```
void avl::ThresholdImage_Relative
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Image& inBaseImage,
 atl::Optional<float> inMinRelativeValue,
 atl::Optional<float> inMaxRelativeValue,
 float inFuzziness,
 avl::Image& outMonoImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inBaseImage	const Image&			Pixels of this image are subtracted from inImage before thresholding
→	inMinRelativeValue	Optional<float>		128.0f	Minimum relative value of a pixel that is considered foreground (Auto = -INF)
→	inMaxRelativeValue	Optional<float>		NIL	Maximum relative value of a pixel that is considered foreground (Auto = +INF)
→	inFuzziness	float	0.0 - ∞	0.0f	A tolerance for inMin/MaxRelativeValue that results in intermediate output values
←	outMonoImage	Image&			

Description

The operation transforms each pixel value of **inImage** to the maximum or minimum level thus creating binary image. The result of the transformation depends on the pixel intensity compared with the intensity of the **inBaseImage** pixels:

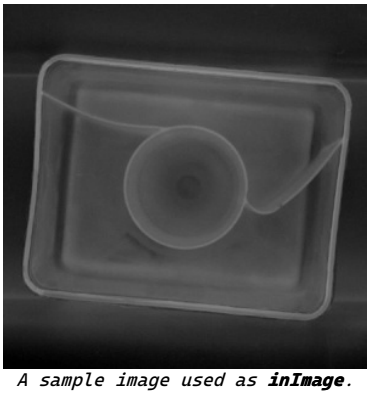
- Pixels that are brighter than corresponding pixels of **inBaseImage** by at least **inMinRelativeValue** and at most **inMaxRelativeValue** are transformed to the maximum level.
- Other pixel values are transformed to the minimum level.

If any of the parameters **inMinRelativeValue**, **inMaxRelativeValue** is not set, it is assumed to be, accordingly, *-infinity* or *infinity*.

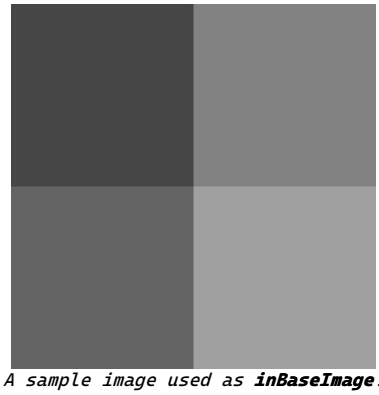
Parameter **inFuzziness** (set to 0 by default) allows to perform fuzzy thresholding which linearly interpolates those pixel values that differ by at most **inFuzziness** from the border intensities; thus creating smooth transition between minimum and maximum values in the resulting image (see **Remarks** section).

In the multichannel images the operation uses an average of channel values in each pixel, thus the resulting image is always monochromatic.

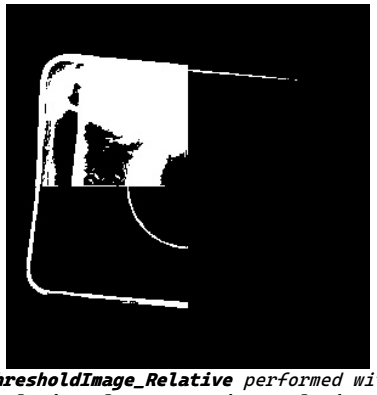
Examples



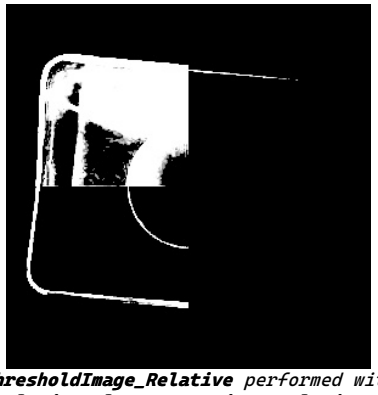
*A sample image used as **inImage**.*



*A sample image used as **inBaseImage**.*



***ThresholdImage_Relative** performed with **inMinRelativeValue** = 0.0, **inMaxRelativeValue** = auto, **inFuzziness** = 0.0.*



***ThresholdImage_Relative** performed with **inMinRelativeValue** = 0.0, **inMaxRelativeValue** = auto, **inFuzziness** = 10.0.*

Remarks

When image pixel type is Real, parameter **inFuzziness** has no influence on the output (input is ignored). The reason is strictly mathematical. Namely, there does not exist a smooth transition between *-infinity* and *infinity* values, which are, correspondingly, minimum and maximum levels of pixel brightness.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in ThresholdImage_Relative.
DomainError	Image sizes are not equal in ThresholdImage_Relative.
DomainError	Region exceeds an input image in ThresholdImage_Relative.

See Also

- ThresholdToRegion_Relative – Thresholds an image with a different threshold value for each pixel (inBaseImage(x, y) + inValue).

ThresholdImage_RGB

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms each pixel value to minimum or maximum depending on whether it belongs to the specified range for each individual pixel component.

Applications: Multi-channel thresholding.

Syntax

```
void avl::ThresholdImage_RGB
(
 const avl::Image& inRgbImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<int> inMinRed,
 atl::Optional<int> inMaxRed,
 atl::Optional<int> inMinGreen,
 atl::Optional<int> inMaxGreen,
 atl::Optional<int> inMinBlue,
 atl::Optional<int> inMaxBlue,
 atl::Optional<int> inMinAlpha,
 atl::Optional<int> inMaxAlpha,
 float inFuzziness,
 avl::Image& outMonoImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRgbImage	const Image&			Input image, usually in the RGB color space
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inMinRed	Optional<int>	0 – 255	128	Minimum for the first pixel component, usually Red (Auto = −INF)
→	inMaxRed	Optional<int>	0 – 255	NIL	Maximum for the first pixel component, usually Red (Auto = +INF)
→	inMinGreen	Optional<int>	0 – 255	128	Minimum for the second pixel component, usually Green (Auto = −INF)
→	inMaxGreen	Optional<int>	0 – 255	NIL	Maximum for the second pixel component, usually Green (Auto = +INF)
→	inMinBlue	Optional<int>	0 – 255	128	Minimum for the third pixel component, usually Blue (Auto = −INF)
→	inMaxBlue	Optional<int>	0 – 255	NIL	Maximum for the third pixel component, usually Blue (Auto = +INF)
→	inMinAlpha	Optional<int>	0 – 255	NIL	Minimum for the fourth pixel component, usually Blue (Auto = −INF)
→	inMaxAlpha	Optional<int>	0 – 255	NIL	Maximum for the fourth pixel component, usually Blue (Auto = +INF)
→	inFuzziness	float	0.0 – ∞		Tolerance for the ranges that results in intermediate output values
←	outMonoImage	Image&			

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 4×uint8.

Read more about pixel formats in Image documentation.

Description

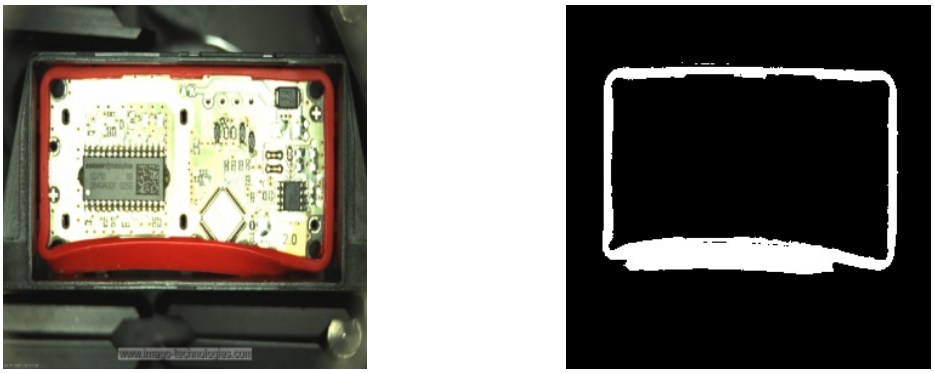
The operation transforms each pixel of three-channel **inRgbImage** to the maximum or minimum level thus creating binary image. The input image is considered to be encoded using RGB color representation.

- Pixels meeting all of the following conditions are transformed to the maximum level:
  - Intensity of the "red" channel is in range (**inMinRed**, **inMaxRed**).
  - Intensity of the "green" channel is in range (**inMinGreen**, **inMaxGreen**).
  - Intensity of the "blue" channel is in range (**inMinBlue**, **inMaxBlue**).
- Other pixels are transformed to the maximum level.

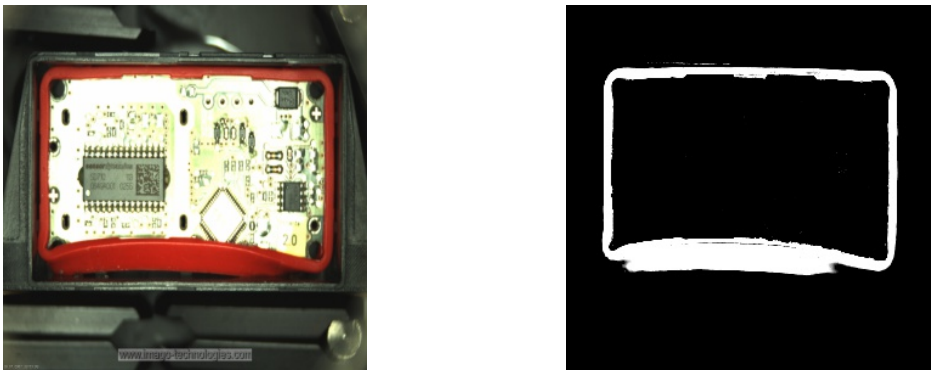
If any of the parameters **inMinRed**, **inMinGreen**, **inMinBlue** is not set, it is assumed to be *-infinity*. If any of the parameters **inMaxRed**, **inMaxGreen**, **inMaxBlue** is not set, it is assumed to be *infinity*.

Parameter **inFuzziness** (set to 0 by default) allows to perform fuzzy thresholding which linearly interpolates those pixel values that differ by at most **inFuzziness** from the border channel intensities; thus creating smooth transition between minimum and maximum values in the resulting image.

Examples



ThresholdImage_RGB *performed on the sample image with* ***inMinRed*** *= 120.0,* ***inMaxGreen*** *= 100.0,* ***inMaxBlue*** *= 100.0,* ***inFuzziness*** *= 0.0.*



ThresholdImage_RGB *performed on the sample image with* ***inMinRed*** *= 120.0,* ***inMaxGreen*** *= 100.0,* ***inMaxBlue*** *= 100.0,* ***inFuzziness*** *= 10.0.*

Hardware Acceleration

This operation is optimized for SSSE4 (for inFuzziness = 0) technology.

This operation is optimized for AVX2 (for inFuzziness = 0) technology.

This operation is optimized for NEON technology for pixels of types: 1xUINT8 (for inFuzziness = 0), 3xUINT8 (for inFuzziness = 0).

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in ThresholdImage_RGB.
DomainError	Region exceeds an input image in ThresholdImage_RGB.
DomainError	Not supported inRgbImage pixel format in ThresholdImage_RGB. Supported formats: 3xUInt8, 4xUInt8.

See Also

- ThresholdToRegion_RGB – Creates a region containing image pixels which belongs to the specified range for each individual pixel component.

ThresholdToRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a region containing image pixels with values within the specified range.

Applications: Extraction of a region of objects that can be defined by a salient brightness.

Syntax

```
void avl::ThresholdToRegion
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 float inHysteresis,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inMinValue	Optional<float>		128.0f	Minimum value of a pixel that is considered foreground (Auto = -INF)
→	inMaxValue	Optional<float>		NIL	Maximum value of a pixel that is considered foreground (Auto = +INF)
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for pixels neighboring with other foreground pixels
←	outRegion	Region&			Output region

Description

The operation is a cousin of ThresholdImage yet computes a region instead of an image. The resulting region contains those pixels of the input image that meet one of the following conditions:

- Pixel value is in range [**inMinValue**, **inMaxValue**].
- Pixel value is in range [**inMinValue**-**inHysteresis**, **inMinValue**) or in range (**inMaxValue**, **inMaxValue**+**inHysteresis**] and in the processed image there is a path of consecutive pixels of value in range [**inMinValue**-**inHysteresis**, **inMaxValue**+**inHysteresis**] that connects the pixel being considered and any pixel with value in range [**inMinValue**, **inMaxValue**].

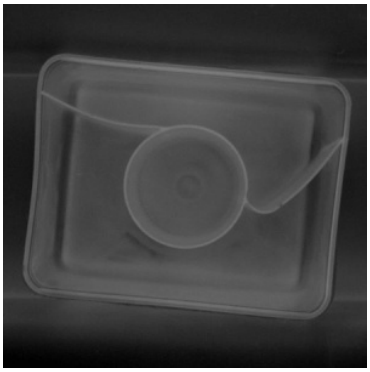
If any of the parameters **inMinValue**, **inMaxValue** is not set, it is assumed to be, accordingly, *-infinity* or *infinity*.

In the multichannel images the operation uses an average of channel values in each pixel.

Hints

- Define **inMinValue** to extract bright objects (brighter than the specified value).
- Define **inMaxValue** to extract dark objects (darker than the specified value).
- Use **inHysteresis** to allow weaker threshold for pixels neighboring with already extracted ones.

Examples



ThresholdToRegion *performed on the sample image with* ***inMinValue*** *= 80.0,* ***inMaxValue*** *= auto.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 3xUINT8, 1xINT16, 1xUINT16.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8, 1xINT16.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdToRegion.

See Also

- ThresholdImage – Transforms each pixel value to maximum or minimum depending on whether they belong to the specified range.

ThresholdToRegion_Color

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a region containing image pixels with values close to the given color.

Applications: Color analysis with a given reference color.

Syntax

```
void avl::ThresholdToRegion_Color
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Pixel& inRgbColor,
 float inChromaAmount,
 float inMaxDifference,
 float inHysteresis,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inRgbColor	const Pixel&			Color to compare the image to
→	inChromaAmount	float	0.0 – 1.0	0.7f	Proportion of chromatic information in distance computation
→	inMaxDifference	float	0.0 – ∞	5.0f	Maximum difference between image pixel and model color
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the difference criterium is lowered for pixels neighboring with other foreground pixels
←	outRegion	Region&			Output region

Requirements

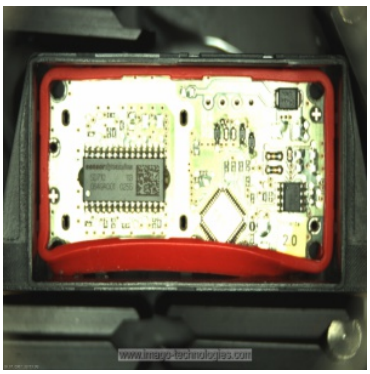
For input **inImage** only pixel formats are supported: 1×uint8, 2×uint8, 3×uint8, 4×uint8.

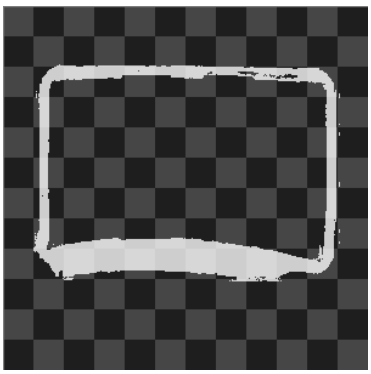
Read more about pixel formats in Image documentation.

Hints

- Define the reference color by setting the **inRgbColor** input.
- Increase **inChromaAmount** to make the filter less sensitive to changes in brightness. Decrease it to make brightness more important.
- Set **inMaxDifference** experimentally to a value that best separates the foreground and background pixels.

Examples





ThresholdToRegion_Color *performed on a sample image with* ***inRgbColor*** *= (192, 34, 22),* ***inChromaAmount*** *= 1.0,* ***inMaxDifference*** *= 48.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdToRegion_Color.
DomainError	Not supported inImage pixel format in ThresholdToRegion_Color. Supported formats: 1xUInt8, 2xUInt8, 3xUInt8, 4xUInt8.

See Also

- ColorDistanceImage – Compares each pixel with the specified color using chromatic and non-chromatic information.

ThresholdToRegion_Dynamic

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thresholds an image relatively to the average pixel value in a local rectangular neighborhood.

Applications: Useful in case of uneven illumination.

Syntax

```
void avl::ThresholdToRegion_Dynamic
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inSourceRoi,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 atl::Optional<float> inMinRelativeValue,
 atl::Optional<float> inMaxRelativeValue,
 float inHysteresis,
 avl::Region& outRegion,
 avl::Image& diagBaseImage
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inRoi	Optional<const Region&>		NIL	Region in which pixels are written
➡	inSourceRoi	Optional<const Region&>		NIL	Region from which pixels are read
➡	inRadiusX	int	0 – 65535	5	Horizontal radius of internal mean blur
➡	inRadiusY	Optional<int>	0 – 65535	NIL	Vertical radius of internal mean blur (Auto = inRadiusX)
➡	inMinRelativeValue	Optional<float>		5.0f	Minimum relative value of a pixel that is considered foreground (Auto = -INF)
➡	inMaxRelativeValue	Optional<float>		NIL	Maximum relative value of a pixel that is considered foreground (Auto = +INF)
➡	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for pixels neighboring with other foreground pixels
⬅	outRegion	Region&			Output region
🔍	diagBaseImage	Image&			Diagnostic blurred image.

Description

The operation is a cousin of ThresholdImage_Dynamic yet computes a region instead of an image. The resulting region contains only those pixels of the input image, which are brighter at least by **inMinRelativeValue** and at most by **inMaxRelativeValue** than the local average. If any of the parameters **inMinRelativeValue**, **inMaxRelativeValue** is not set, it is assumed to be, accordingly, -infinity or infinity.

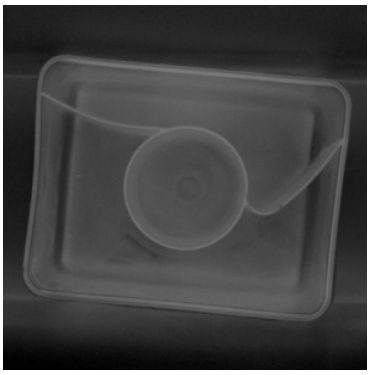
Pixel neighbourhood used to compute the local average is a rectangle of dimensions $(2 \cdot \mathbf{inRadiusX} + 1) \times (2 \cdot \mathbf{inRadiusY} + 1)$ centered at the pixel being processed.

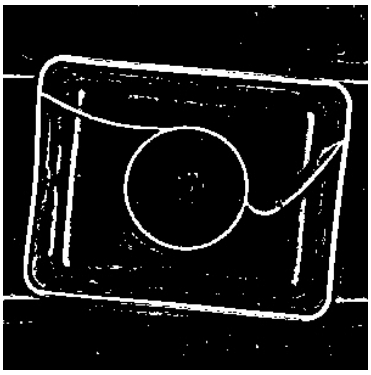
In the multichannel images the operation uses an average of channel values in each pixel.

Hints

- Define **inMinRelativeValue** to extract objects which are brighter than the neighborhood.
- Define **inMaxRelativeValue** to extract objects which are darker than the neighborhood.
- Increase **inRadiusX** (and optionally **inRadiusY**) to define a bigger neighborhood.

Examples





ThresholdToRegion_Dynamic *performed on the sample image with* ***inMinRelativeValue*** *= 5.0,* ***inMaxRelativeValue*** *= auto.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ThresholdToRegion_Dynamic.
DomainError	Roi exceeds image dimensions in ThresholdToRegion_Dynamic.
DomainError	Source roi exceeds image dimensions in ThresholdToRegion_Dynamic.

See Also

- ThresholdImage_Dynamic – Thresholds an image relatively to some value calculated in a local rectangular neighbourhood.

ThresholdToRegion_HSx

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a region containing image pixels which belongs to specified region in HSV, HSL or HSI space.

Applications: Extraction of a region characterized with a specific color.

Syntax

```
void avl::ThresholdToRegion_HSx
(
 const avl::Image& inRgbImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::HSxColorModel::Type inColorModel,
 int inBeginHue,
 int inEndHue,
 atl::Optional<int> inMinSaturation,
 atl::Optional<int> inMaxSaturation,
 atl::Optional<int> inMinBrightness,
 atl::Optional<int> inMaxBrightness,
 avl::Region& outRegion,
 avl::Image& diagHSxImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRgbImage	const Image&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inColorModel	const HSxColorModel::Type			Selected color model
→	inBeginHue	int	0 – 255	0	Lowest acceptable Hue; if higher than inEndHue, then range wrapping is used
→	inEndHue	int	0 – 255	255	Highest acceptable Hue, if lower than inBeginHue, then range wrapping is used
→	inMinSaturation	Optional<int>	0 – 255	128	
→	inMaxSaturation	Optional<int>	0 – 255	NIL	
→	inMinBrightness	Optional<int>	0 – 255	128	Minimum brightness; denotes V, L or I, depending on inColorModel
→	inMaxBrightness	Optional<int>	0 – 255	NIL	Maximum brightness; denotes V, L or I, depending on inColorModel
←	outRegion	Region&			Output region
🔍	diagHSxImage	Image&			Diagnostic image in HSx color space

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Description

The operation is a cousin of ThresholdImage_HSx yet it computes a region instead of an image. The three-channel **inRgbImage** is considered to be encoded using RGB color representation. Each of the image pixel is internally converted to HSx (HSV, HSL or HSI) color representation and then examined. The resulting region contains only those pixels of the input image, which meets all of the following conditions:

- Value of the Hue parameter is in cyclic range (**inBeginHue**, **inEndHue**).
- Value of the Saturation parameter is in range (**inMinSaturation**, **inMaxSaturation**).
- Value of the Value parameter is in range (**inMinBrightness**, **inMaxBrightness**).

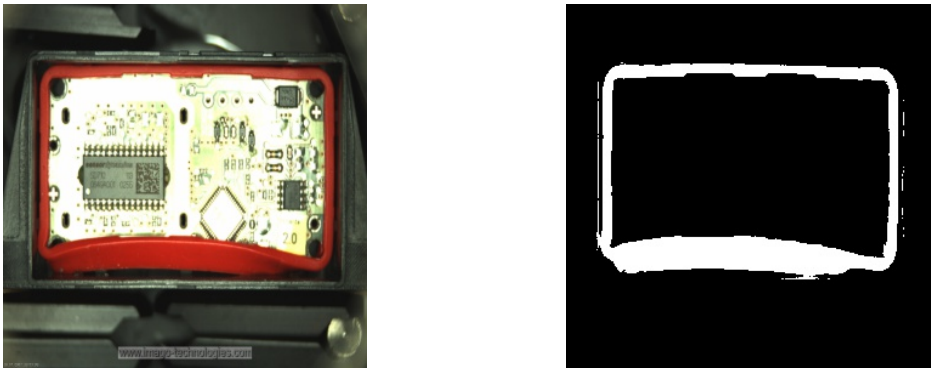
If any of the parameters **inMinSaturation**, **inMinBrightness** is not set, it is assumed to be -infinity.

If any of the parameters **inMaxSaturation**, **inMaxBrightness** is not set, it is assumed to be infinity.

Hints

- Choose **inColorModel** taking into account accuracy and execution speed (HSV is the fastest, HSI is usually the most accurate).
- Define the range of HSV/HSL/HSI values that best separates the foreground and background pixels. Analyze the results on the **outRegion** output.

Examples



ThresholdToRegion_HSx *performed on the sample image with* ***inColorModel*** *= HSV,* ***inBeginHue*** *= 0.0,* ***inEndHue*** *= 10.0,* ***inMinSaturation*** *= 120.0,* ***inMinBrightness*** *= 70.0.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not a 3-channel and 8-bit image in ThresholdToRegion_HSx.
DomainError	Region exceeds an input image in ThresholdToRegion_HSx.
DomainError	Not supported inRgbImage pixel format in ThresholdToRegion_HSx. Supported formats: 3xUInt8.

See Also

- ThresholdImage_HSx – Transforms each pixel value to minimum or maximum depending on whether it belongs to specified region in the HSV, HSL or HSI color space.

ThresholdToRegion_Relative

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thresholds an image with a different threshold value for each pixel (inBaseImage(x, y) + inValue).

Syntax

```
void avl::ThresholdToRegion_Relative
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Image& inBaseImage,
 atl::Optional<float> inMinRelativeValue,
 atl::Optional<float> inMaxRelativeValue,
 float inHysteresis,
 avl::Region& outRegion
)
```

Parameters

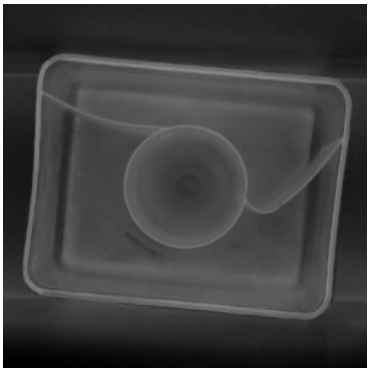
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inBaseImage	const Image&			Pixels of this image are subtracted from inImage before thresholding
→	inMinRelativeValue	Optional<float>		128.0f	Minimum relative value of a pixel that is considered foreground (Auto = -INF)
→	inMaxRelativeValue	Optional<float>		NIL	Maximum relative value of a pixel that is considered foreground (Auto = +INF)
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for pixels neighboring with other foreground pixels
←	outRegion	Region&			Output region

Description

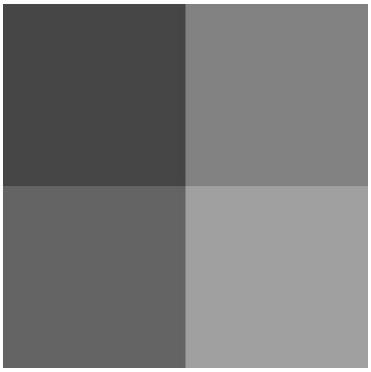
The operation is a cousin of ThresholdImage_Relative yet computes a region instead of an image. The resulting region contains only those pixels of the input image, which are brighter at least by **inMinRelativeValue** and at most by **inMaxRelativeValue** than the corresponding pixel of **inBaseImage**. If any of the parameters **inMinRelativeValue**, **inMaxRelativeValue** is not set, it is assumed to be, accordingly, -infinity or infinity.

In the multichannel images the operation uses an average of channel values in each pixel.

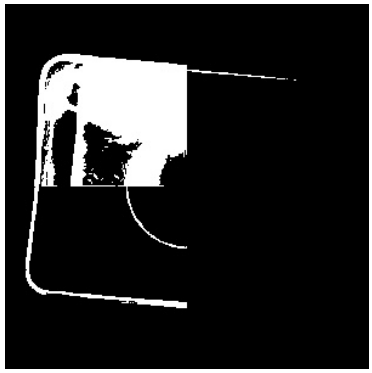
Examples



*A sample image used as **inImage**.*



*A sample image used as **inBaseImage**.*



ThresholdToRegion_Relative performed with **inMinRelativeValue** = 0.0, **inMaxRelativeValue** = auto.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in ThresholdToRegion_Relative.
DomainError	Image sizes are not equal in ThresholdToRegion_Relative.
DomainError	Region exceeds an input image in ThresholdToRegion_Relative.

See Also

- ThresholdImage_Relative – Thresholds an image with a different threshold value for each pixel (inBaseImage(x, y) + inValue).

ThresholdToRegion_Relative_DarkBright

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Thresholds an image using two relative thresholds and produces two regions (Dark and Bright) in a single image pass.

Applications: This filter can replace two instances of ThresholdToRegion_Relative which may slightly improve performance.

Syntax

```
void avl::ThresholdToRegion_Relative_DarkBright
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Image& inBaseImage,
 float inDarkThreshold,
 float inBrightThreshold,
 float inHysteresis,
 avl::Region& outDarkRegion,
 avl::Region& outBrightRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inBaseImage	const Image&			Pixels of this image are subtracted from inImage before thresholding
→	inDarkThreshold	float		64.0f	Maximum relative value of a pixel that is considered DarkRegion
→	inBrightThreshold	float		192.0f	Minimum relative value of a pixel that is considered BrightRegion
→	inHysteresis	float	0.0 – ∞	0.0f	Defines how much the threshold criteria are lowered for pixels neighboring with other foreground pixels
←	outDarkRegion	Region&			Region of pixels equal or lower than inDarkThreshold
←	outBrightRegion	Region&			Region of pixels equal or greater than inBrightThreshold

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image formats are not the same in ThresholdToRegion_Relative_DarkBright.
DomainError	Image sizes are not equal in ThresholdToRegion_Relative_DarkBright.
DomainError	Region exceeds an input image in ThresholdToRegion_Relative_DarkBright.

ThresholdToRegion_RGB

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a region containing image pixels which belongs to the specified range for each individual pixel component.

Applications: Multi-channel thresholding.

Syntax

```
void avl::ThresholdToRegion_RGB
(
 const avl::Image& inRgbImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<int> inMinRed,
 atl::Optional<int> inMaxRed,
 atl::Optional<int> inMinGreen,
 atl::Optional<int> inMaxGreen,
 atl::Optional<int> inMinBlue,
 atl::Optional<int> inMaxBlue,
 atl::Optional<int> inMinAlpha,
 atl::Optional<int> inMaxAlpha,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRgbImage	const Image&			Input image, usually in the RGB color space
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inMinRed	Optional<int>	0 – 255	128	Minimum for the first pixel component, usually Red (Auto = −INF)
→	inMaxRed	Optional<int>	0 – 255	NIL	Maximum for the first pixel component, usually Red (Auto = +INF)
→	inMinGreen	Optional<int>	0 – 255	128	Minimum for the second pixel component, usually Green (Auto = −INF)
→	inMaxGreen	Optional<int>	0 – 255	NIL	Maximum for the second pixel component, usually Green (Auto = +INF)
→	inMinBlue	Optional<int>	0 – 255	128	Minimum for the third pixel component, usually Blue (Auto = −INF)
→	inMaxBlue	Optional<int>	0 – 255	NIL	Maximum for the third pixel component, usually Blue (Auto = +INF)
→	inMinAlpha	Optional<int>	0 – 255	NIL	Minimum for the fourth pixel component, usually Blue (Auto = −INF)
→	inMaxAlpha	Optional<int>	0 – 255	NIL	Maximum for the fourth pixel component, usually Blue (Auto = +INF)
←	outRegion	Region&			Output region

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8, 4×uint8.

Read more about pixel formats in Image documentation.

Description

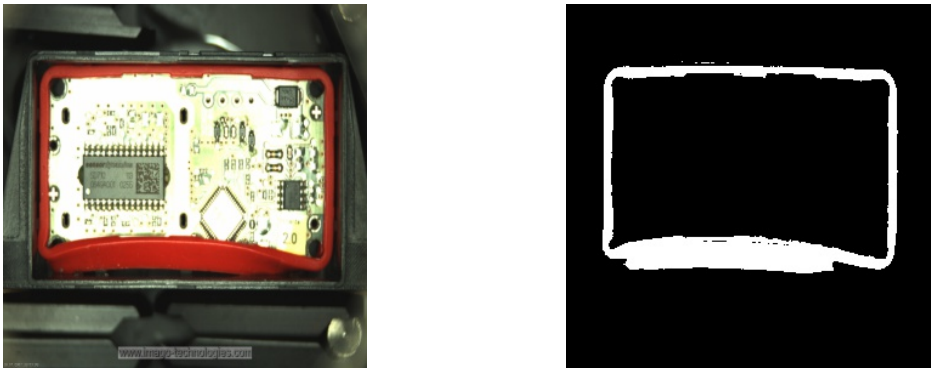
The operation is a cousin of ThresholdImage_RGB yet it computes a region instead of an image. The three-channel **inRgbImage** is considered to be encoded using RGB color representation. The resulting region contains only those pixels of the input image, which meets all of the following conditions:

- Intensity of the "red" channel is in range (**inMinRed**, **inMaxRed**).
- Intensity of the "green" channel is in range (**inMinGreen**, **inMaxGreen**).
- Intensity of the "blue" channel is in range (**inMinBlue**, **inMaxBlue**).

If any of the parameters **inMinRed**, **inMinGreen**, **inMinBlue** is not set, it is assumed to be -infinity.

If any of the parameters **inMaxRed**, **inMaxGreen**, **inMaxBlue** is not set, it is assumed to be infinity.

Examples



ThresholdToRegion_RGB *performed on the sample image with* ***inMinRed*** *= 120.0,* ***inMaxGreen*** *= 100.0,* ***inMaxBlue*** *= 100.0.*

Hardware Acceleration

This operation is optimized for SSE41 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not an 8-bit image in ThresholdToRegion_RGB.
DomainError	Region exceeds an input image in ThresholdToRegion_RGB.
DomainError	Unsupported image depth in ThresholdToRegion_RGB.
DomainError	Not supported inRgbImage pixel format in ThresholdToRegion_RGB. Supported formats: 3xUInt8, 4xUInt8.

- ThresholdImage_RGB – Transforms each pixel value to minimum or maximum depending on whether it belongs to the specified range for each individual pixel component.

61. HandEyeCalibration Calibration

Table of content:

- CalibrateEyeInHand
- CalibrateEyeInHandDataPrep
- EstimateAffine3DTransform

CalibrateEyeInHand

Header: AVL.h
Namespace: avl
Module: Calibration

Computes Hand-Eye calibration matrices.

Syntax

```
void avl::CalibrateEyeInHand
(
 const atl::Array<avl::Matrix>& inRotationGripperToBase,
 const atl::Array<avl::Matrix>& inTranslationGripperToBase,
 const atl::Array<avl::Matrix>& inRotationTargetToCam,
 const atl::Array<avl::Matrix>& inTranslationTargetToCam,
 const avl::HandEyeCalibrationMethod::Type inCalibrationMethod,
 avl::Matrix& outRotationCamToGripper,
 avl::Matrix& outTranslationCamToGripper
)
```

Parameters

	Name	Type	Default	Description
→	inRotationGripperToBase	const Array<Matrix>&		Rotation part extracted from the homogeneous matrix that transforms a point expressed in the gripper frame to the robot base frame.
→	inTranslationGripperToBase	const Array<Matrix>&		Translation part extracted from the homogeneous matrix that transforms a point expressed in the gripper frame to the robot base frame.
→	inRotationTargetToCam	const Array<Matrix>&		Rotation part extracted from the homogeneous matrix that transforms a point expressed in the target frame to the camera frame.
→	inTranslationTargetToCam	const Array<Matrix>&		Translation part extracted from the homogeneous matrix that transforms a point expressed in the target frame to the camera frame
→	inCalibrationMethod	const HandEyeCalibrationMethod::Type		Calibration method.
←	outRotationCamToGripper	Matrix&		Estimated rotation part extracted from the homogeneous matrix that transforms a point expressed in the camera frame to the gripper frame.
←	outTranslationCamToGripper	Matrix&		Estimated translation part extracted from the homogeneous matrix that transforms a point expressed in the camera frame to the gripper frame.

Errors

List of possible exceptions:

Error type	Description
DomainError	All of the arrays should have the same number of measurements.
DomainError	At least 3 measurements are needed.

CalibrateEyeInHandDataPrep

Header: AVL.h
Namespace: avl
Module: Calibration

Compute the transformation between the camera and the calibration target reference frames. (all units in mm)

Syntax

```
void avl::CalibrateEyeInHandDataPrep
(
 const atl::Array<avl::Image>& inCalibrationTargetImages,
 const atl::Array<avl::Point3DGrid>& inCalibrationTargetPoints,
 const atl::Optional<float>& inCalibrationTargetSquareSize,
 const avl::Size& inCalibrationTargetSize,
 atl::Array<avl::Matrix>& outRotationTargetToCam,
 atl::Array<avl::Matrix>& outTranslationTargetToCam,
 atl::Array<bool>& outDetectionStatus,
 atl::Array<avl::Image>& diagShowDetectedCorners2D,
 atl::Array<avl::Point3DGrid>& diagShowCorners3DCameraRef,
 atl::Array<avl::Point3DGrid>& diagShow3DCorners3DTargetRef
)
```

Parameters

	Name	Type	Default	Description
→	inCalibrationTargetImages	const Array<Image>&		Input Intensity images of the calibration target. Calibration target should be visible in all images.
→	inCalibrationTargetPoints	const Array<Point3DGrid>&		Input 3D point Cloud of the calibration target. Calibration target should be visible in all images.
→	inCalibrationTargetSquareSize	const Optional<float>&	NIL	Side length of the Square in chessboard calibration target in mm. If not specified, the size will be estimated from the input Point Cloud.
→	inCalibrationTargetSize	const Size&		Number of Rows and Columns in the chessboard calibration target.
←	outRotationTargetToCam	Array<Matrix>&		Estimated rotation part of the homogeneous transformation matrix that transforms a point expressed in the camera frame to the Target frame.
←	outTranslationTargetToCam	Array<Matrix>&		Estimated translation part of the homogeneous transformation matrix that transforms a point expressed in the camera frame to the Target frame.
←	outDetectionStatus	Array<bool>&		Output status of the detection of the calibration target in each image.
🔍	diagShowDetectedCorners2D	Array<Image>&		Calibration Target Images annotated with detected corners.
🔍	diagShowCorners3DCameraRef	Array<Point3DGrid>&		Position of the chessboard corners in Camera Reference Frame
🔍	diagShow3DCorners3DTargetRef	Array<Point3DGrid>&		Position of the chessboard corners in Calibration Target Reference Frame

Errors

List of possible exceptions:

Error type	Description
DomainError	All images should have the same size.
DomainError	All point clouds should have the same size.
DomainError	At least 3 images are needed.
DomainError	Number of images and Point Cloud should be same.
DomainError	The Size of a square in calibration should be greater than 10 mm
DomainError	The Size of the calibration should be greater then 4x4 rows, columns.
DomainError	The size of the image and the point cloud should be the same.

EstimateAffine3DTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Computes optimal affine transformation between two 3D point sets.

Syntax

```
void avl::EstimateAffine3DTransform
(
 const atl::Array<avl::Point3D>& inSrcpt,
 const atl::Array<avl::Point3D>& inDstpt,
 float inRansacThreshold,
 float inConfidence,
 avl::Matrix& outTransform,
 atl::Array<int>& outOutliers,
 int& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSrcpt	const Array<Point3D>&			List of 3D points in the source coordinate system.
→	inDstpt	const Array<Point3D>&			List of 3D points in the destination coordinate system.
→	inRansacThreshold	float		3.0f	Maximum reprojection error in the RANSAC algorithm to consider a point as an inlier.
→	inConfidence	float	0.0 – 1.0	0.99f	Confidence level, between 0 and 1, for the estimated transformation. Anything between 0.95 and 0.99 is usually good enough. Values too close to 1 can slow down the estimation significantly. Values lower than 0.8–0.9 can result in an incorrectly estimated transformation.
←	outTransform	Matrix&			Estimated affine transformation matrix.
←	outOutliers	Array<int>&			Output vector indicating which points are outliers (1–inlier, 0–outlier).
←	outValue	int&			

Errors

List of possible exceptions:

Error type	Description
DomainError	EstimateAffine3DTransform failed to find a solution.
DomainError	Input arrays must have at least 4 points in EstimateAffine3DTransform.
DomainError	Input arrays must have the same number of points in EstimateAffine3DTransform.

62. Geometry 2D Intersections

Table of content:

CircleCircleIntersection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes common points of two circles.

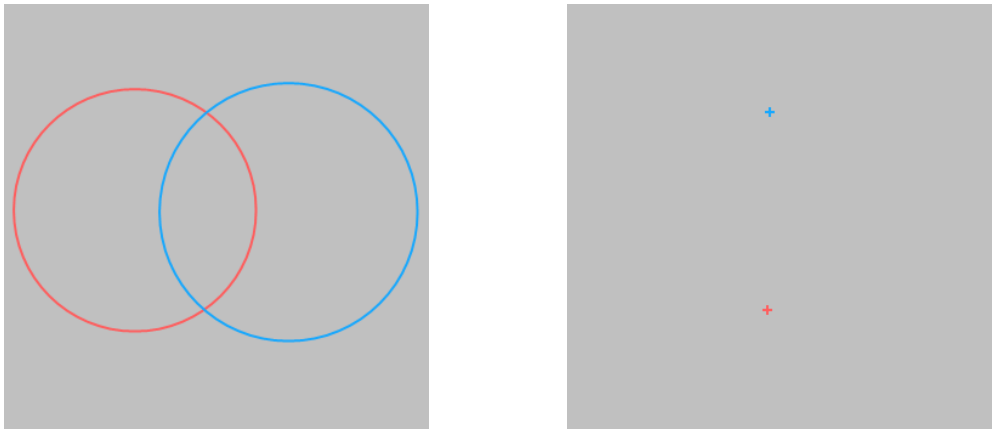
Syntax

```
void avl::CircleCircleIntersection
(
 const avl::Circle2D& inCircle1,
 const avl::Circle2D& inCircle2,
 atl::Conditional<avl::Point2D>& outIntersectionPoint1,
 atl::Conditional<avl::Point2D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inCircle1	const Circle2D&		
→	inCircle2	const Circle2D&		
←	outIntersectionPoint1	Conditional<Point2D>&		
←	outIntersectionPoint2	Conditional<Point2D>&		

Examples



CircleCircleIntersection *performed on two circles.*

LineArcIntersection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common points of an arc and a line.

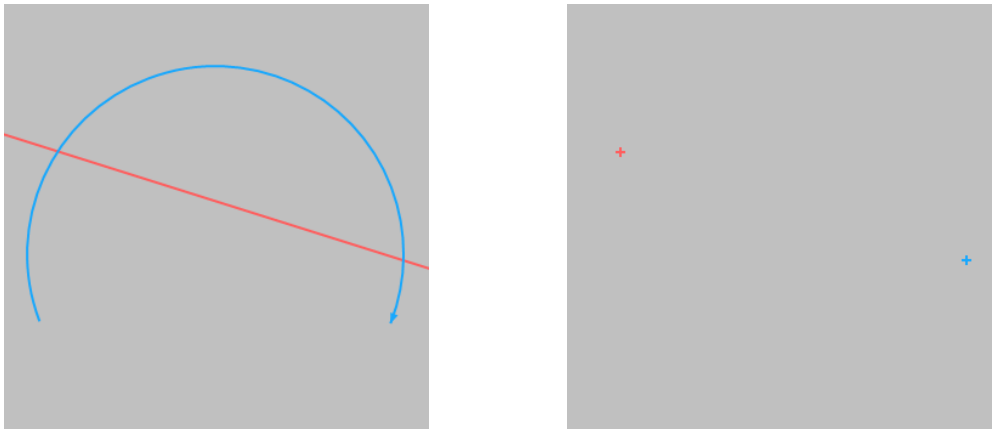
Syntax

```
void avl::LineArcIntersection
(
 const avl::Line2D& inLine,
 const avl::Arc2D& inArc,
 atl::Conditional<avl::Point2D>& outIntersectionPoint1,
 atl::Conditional<avl::Point2D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inArc	const Arc2D&		
←	outIntersectionPoint1	Conditional<Point2D>&		
←	outIntersectionPoint2	Conditional<Point2D>&		

Examples



LineArcIntersection *performed on line and arc.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LineArcIntersection.

LineCircleIntersection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes common points of a circle and a line.

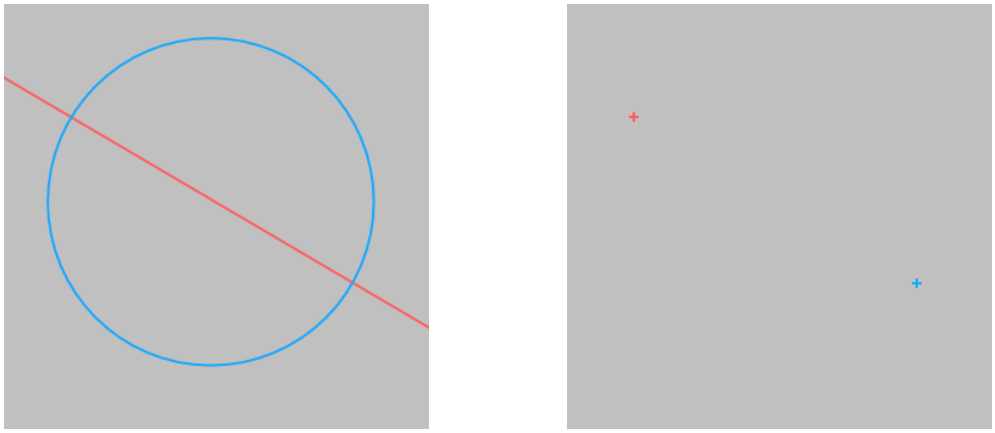
Syntax

```
void avl::LineCircleIntersection
(
 const avl::Line2D& inLine,
 const avl::Circle2D& inCircle,
 atl::Conditional<avl::Point2D>& outIntersectionPoint1,
 atl::Conditional<avl::Point2D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inCircle	const Circle2D&		
←	outIntersectionPoint1	Conditional<Point2D>&		
←	outIntersectionPoint2	Conditional<Point2D>&		

Examples



LineCircleIntersection *performed on line and circle.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LineCircleIntersection.

LineLineIntersection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a common point of two lines.

Syntax

```
void avl::LineLineIntersection
(
 const avl::Line2D& inLine1,
 const avl::Line2D& inLine2,
 atl::Conditional<avl::Point2D>& outIntersectionPoint
)
```

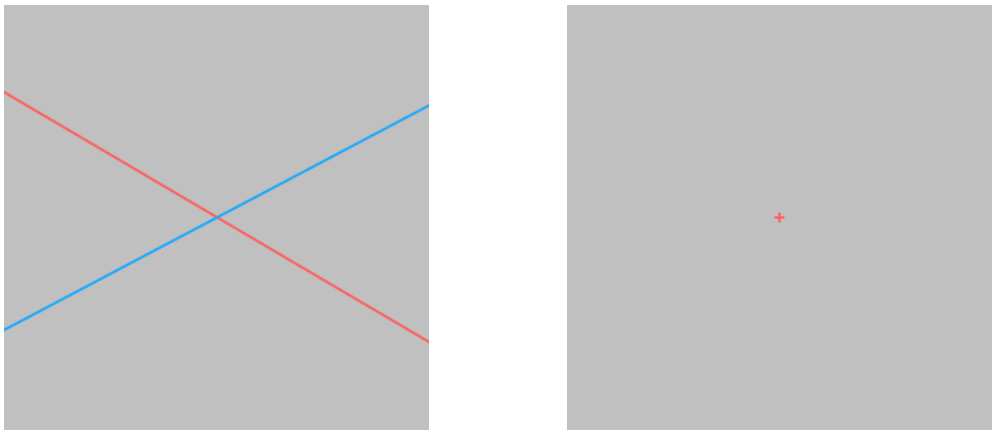
Parameters

	Name	Type	Default	Description
→	inLine1	const Line2D&		
→	inLine2	const Line2D&		
←	outIntersectionPoint	Conditional<Point2D>&		

Hints

- Whenever possible, prefer LineSegmentIntersection instead as it is more numerically stable for near-parallel lines.

Examples



***LineLineIntersection** performed on two lines.*

See Also

- LineSegmentIntersection – Computes a common point of a line and a segment.
- SegmentSegmentIntersection – Computes a common point of two segments.

LineSegmentIntersection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a common point of a line and a segment.

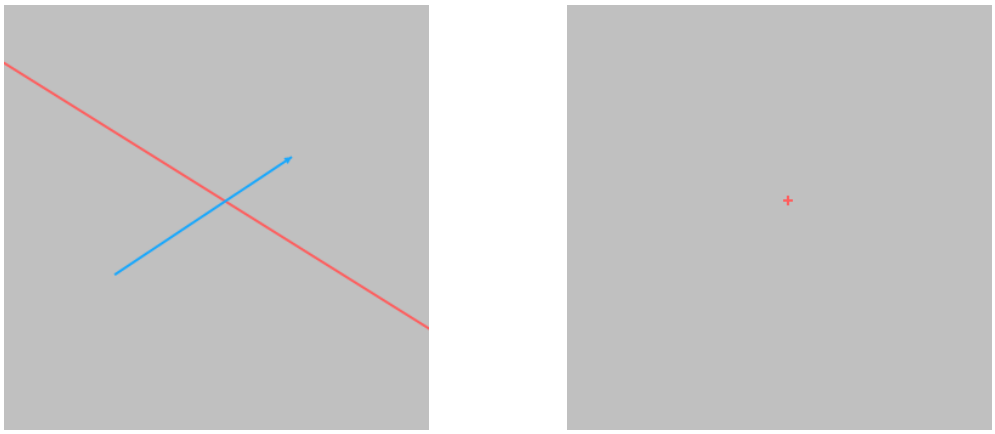
Syntax

```
void avl::LineSegmentIntersection
(
 const avl::Line2D& inLine,
 const avl::Segment2D& inSegment,
 atl::Conditional<avl::Point2D>& outIntersectionPoint
)
```

Parameters

	Name	Type	Default	Description
→	inLine	const Line2D&		
→	inSegment	const Segment2D&		
←	outIntersectionPoint	Conditional<Point2D>&		

Examples



LineSegmentIntersection *performed on line and segment.*

See Also

- SegmentSegmentIntersection – Computes a common point of two segments.

SegmentArcIntersection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common points of an arc and a segment.

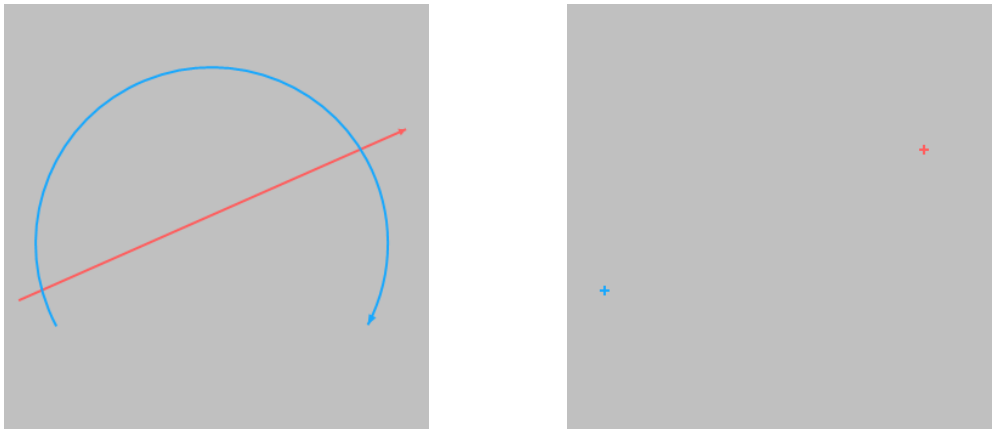
Syntax

```
void avl::SegmentArcIntersection
(
 const avl::Segment2D& inSegment,
 const avl::Arc2D& inArc,
 atl::Conditional<avl::Point2D>& outIntersectionPoint1,
 atl::Conditional<avl::Point2D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inArc	const Arc2D&		
←	outIntersectionPoint1	Conditional<Point2D>&		
←	outIntersectionPoint2	Conditional<Point2D>&		

Examples



SegmentArcIntersection *performed on segment and arc.*

SegmentArrayIntersections

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a common points or segment of any segments from the set.

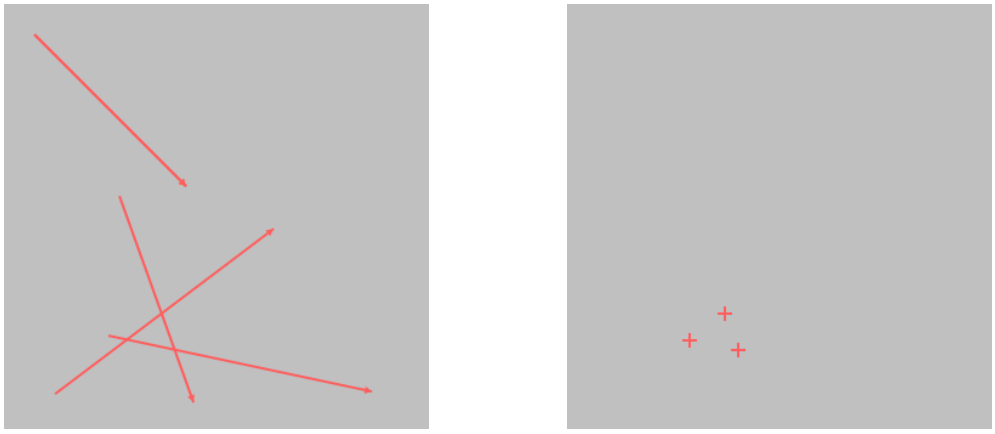
Syntax

```
void avl::SegmentArrayIntersections
(
 const atl::Array<avl::Segment2D>& inSegments,
 atl::Array<avl::Point2D>& outIntersectionPoints,
 atl::Array<int>& outFirstIntersectionIndices,
 atl::Array<int>& outSecondIntersectionIndices,
 atl::Array<avl::Segment2D>& outOverlapSegments,
 atl::Array<int>& outFirstOverlapIndices,
 atl::Array<int>& outSecondOverlapIndices
)
```

Parameters

	Name	Type	Default	Description
→	inSegments	const Array<Segment2D>&		Input segments
←	outIntersectionPoints	Array<Point2D>&		Intersection points
←	outFirstIntersectionIndices	Array<int>&		First indices of the input segments which corresponds to the intersection points
←	outSecondIntersectionIndices	Array<int>&		Second indices of the input segments which corresponds to the intersection points
←	outOverlapSegments	Array<Segment2D>&		Overlap segments
←	outFirstOverlapIndices	Array<int>&		First indices of the input segments which corresponds to the overlap segments
←	outSecondOverlapIndices	Array<int>&		Second indices of the input segments which corresponds to the overlap segments

Examples



SegmentArrayIntersections *performed on segments.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

SegmentCircleIntersection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common points of a circle and a segment.

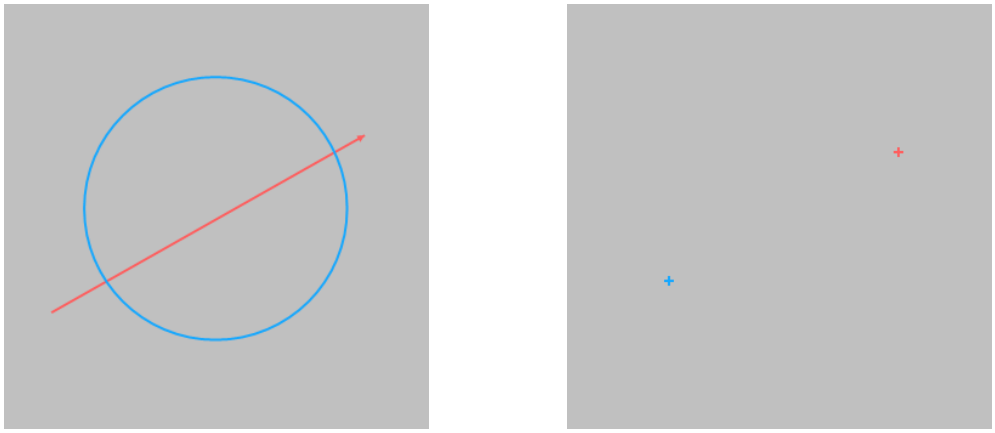
Syntax

```
void avl::SegmentCircleIntersection
(
 const avl::Segment2D& inSegment,
 const avl::Circle2D& inCircle,
 atl::Conditional<avl::Point2D>& outIntersectionPoint1,
 atl::Conditional<avl::Point2D>& outIntersectionPoint2
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inCircle	const Circle2D&		
←	outIntersectionPoint1	Conditional<Point2D>&		
←	outIntersectionPoint2	Conditional<Point2D>&		

Examples



SegmentCircleIntersection *performed on segment and circle.*

SegmentSegmentIntersection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a common point of two segments.

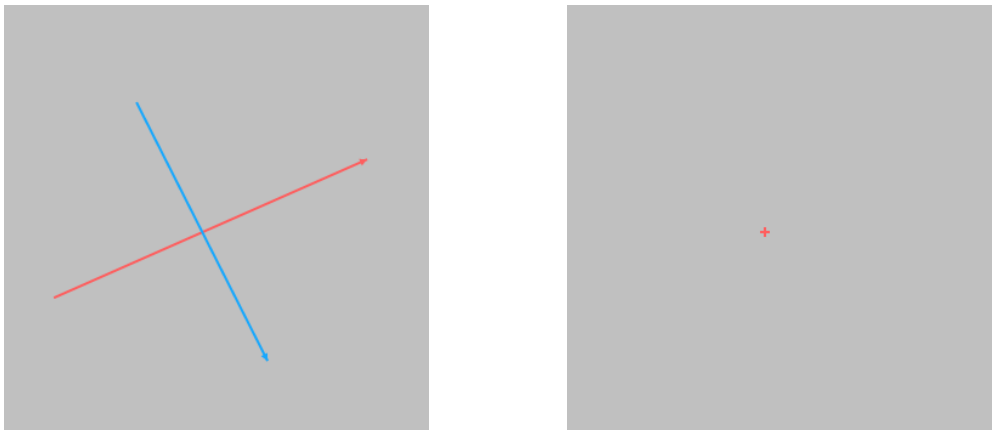
Syntax

```
void avl::SegmentSegmentIntersection
(
 const avl::Segment2D& inSegment1,
 const avl::Segment2D& inSegment2,
 atl::Conditional<avl::Point2D>& outIntersectionPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSegment1	const Segment2D&		
→	inSegment2	const Segment2D&		
←	outIntersectionPoint	Conditional<Point2D>&		

Examples



SegmentSegmentIntersection *performed on two segments.*

See Also

- LineSegmentIntersection – Computes a common point of a line and a segment.

TestRectangleIntersectsWith

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests if two rectangles intersect.

Syntax

```
void avl::TestRectangleIntersectsWith
(
 const avl::Rectangle2D& inRectangle,
 const avl::Rectangle2D& inReferenceRectangle,
 bool& outRectanglesIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inReferenceRectangle	const Rectangle2D&		
←	outRectanglesIntersect	bool&

CircleTangents

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes circle tangent lines passing through a point.

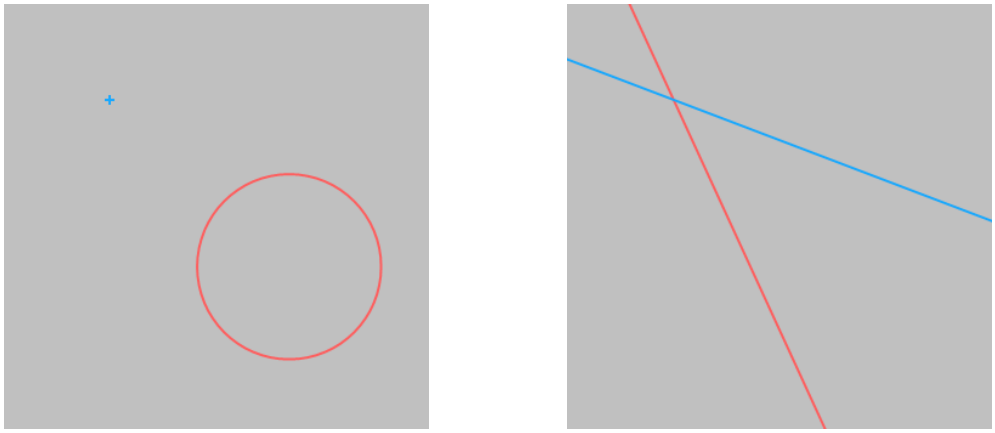
Syntax

```
void avl::CircleTangents
(
 const avl::Circle2D& inCircle,
 const avl::Point2D& inPoint,
 atl::Conditional<avl::Line2D>& outTangentLine1,
 atl::Conditional<avl::Line2D>& outTangentLine2
)
```

Parameters

	Name	Type	Default	Description
→	inCircle	const Circle2D&		
→	inPoint	const Point2D&		
←	outTangentLine1	Conditional<Line2D>&		
←	outTangentLine2	Conditional<Line2D>&		

Examples



CircleTangents *performed on circle and point.*

CircleThroughPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a circle passing through three noncollinear points.

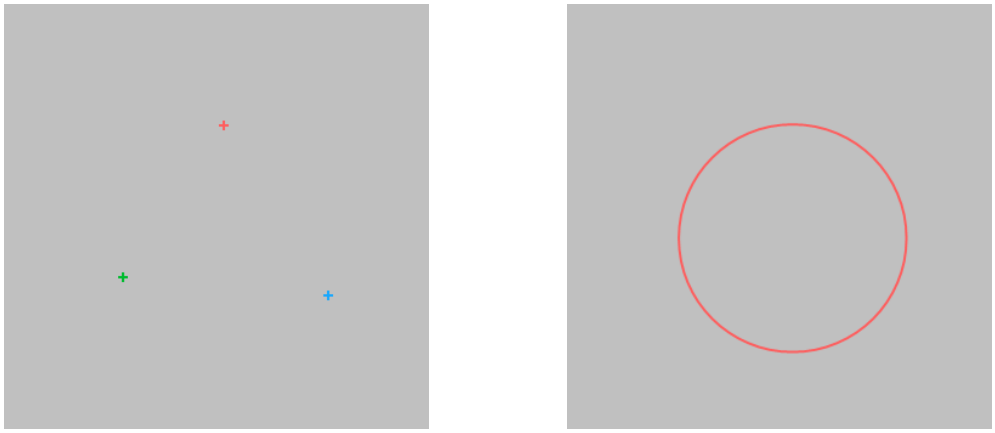
Syntax

```
void avl::CircleThroughPoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 const avl::Point2D& inPoint3,
 atl::Conditional<avl::Circle2D>& outCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		
→	inPoint2	const Point2D&		
→	inPoint3	const Point2D&		
←	outCircle	Conditional<Circle2D>&		Circle passing through the specified points; or Nil if the points are collinear

Examples



CircleThroughPoints *performed on three points.*

CreateCoordinateSystemFromPoint

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a coordinate system with the specified origin.

Applications: Most often used to define an object alignment from results of 1D Edge Detection or Blob Analysis.

Syntax

```
void avl::CreateCoordinateSystemFromPoint
(
 const avl::Point2D& inPoint,
 float inAngle,
 float inScale,
 float inScaleDivisor,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

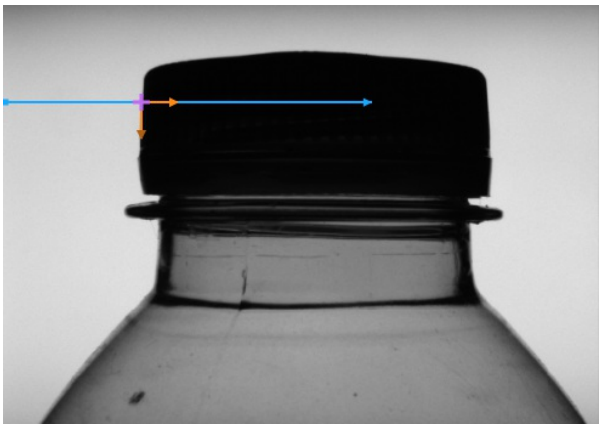
Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			Origin of the created coordinate system
→	inAngle	float			
→	inScale	float	0.001 – ∞	1.0f	
→	inScaleDivisor	float	0.001 – ∞	1.0f	
←	outCoordinateSystem	CoordinateSystem2D&			

Hints

- Pass **inPoint** to a computed point, where you want to anchor a new coordinate system.
- Optionally set **inAngle** to define the rotation.
- Optionally set **inScale** and **inScaleDivisor** to obtain a custom scale.

Examples



A local coordinate system created from a point. Here, the point is located with a 1D Edge Detection filter.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

CreateCoordinateSystemFromRectangle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a coordinate system from a rectangle.

Applications: Most often used to define an object alignment from a filter like RegionBoundingRectangle.

Syntax

```
void avl::CreateCoordinateSystemFromRectangle
(
 const avl::Rectangle2D& inRectangle,
 const avl::Anchor2D::Type inPointAnchor,
 float inRelativeAngle,
 float inScale,
 float inScaleDivisor,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

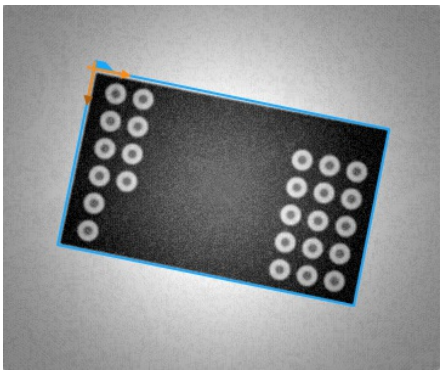
Parameters

	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			
→	inPointAnchor	const Anchor2D::Type		TopLeft	
→	inRelativeAngle	float			
→	inScale	float	0.001 – ∞	1.0f	
→	inScaleDivisor	float	0.001 – ∞	1.0f	
←	outCoordinateSystem	CoordinateSystem2D&			

Hints

- Pass **inRectangle** to a computed rectangle representing a new coordinate system.
- Optionally set **inScale** and **inScaleDivisor** to obtain a custom scale.
- Optionally set **inRelativeAngle** to modify the rotation.

Examples



A local coordinate system created from a rectangle.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

CreateCoordinateSystemFromSegment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a coordinate system with the origin on a given segment.

Syntax

```
void avl::CreateCoordinateSystemFromSegment
(
 const avl::Segment2D& inSegment,
 float inPointAnchor,
 float inRelativeAngle,
 float inScale,
 float inScaleDivisor,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment	const Segment2D&			
→	inPointAnchor	float	-1.0 – 1.0	0.0f	
→	inRelativeAngle	float			
→	inScale	float	0.001 – ∞	1.0f	
→	inScaleDivisor	float	0.001 – ∞	1.0f	
←	outCoordinateSystem	CoordinateSystem2D&			

Hints

- Pass **inSegment** to a computed segment representing the origin and the rotation of a new coordinate system.
- Optionally set **inScale** and **inScaleDivisor** to obtain a custom scale.
- Optionally set **inPointAnchor** and/or **inRelativeAngle** to modify the origin and the rotation.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

CreateCoordinateSystemFromTwoPoints

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a coordinate system with two points on its axes.

Applications: Most often used to define an object alignment from results of two 1D Edge Detection scans, each of which locates one side of a rectangular object.

Syntax

```
void avl::CreateCoordinateSystemFromTwoPoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 float inAngle,
 float inScale,
 float inScaleDivisor,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint1	const Point2D&			
→	inPoint2	const Point2D&			
→	inAngle	float			
→	inScale	float	0.001 – ∞	1.0f	
→	inScaleDivisor	float	0.001 – ∞	1.0f	
←	outCoordinateSystem	CoordinateSystem2D&			

Hints

- Pass **inPoint1** and **inPoint2** to computed points lying on (respectively) the X and the Y axes of a new coordinate system.
- Optionally set **inAngle** to define the rotation.
- Optionally set **inScale** and **inScaleDivisor** to obtain a custom scale.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

CreateCoordinateSystemFromVector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a coordinate system from a vector.

Applications: Both vectors and coordinate systems can represent object translations. This operation does a conversion.

Syntax

```
void avl::CreateCoordinateSystemFromVector
(
 const avl::Vector2D& inVector,
 float inAngle,
 float inScale,
 float inScaleDivisor,
 avl::CoordinateSystem2D& outCoordinateSystem
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVector	const Vector2D&			
→	inAngle	float			
→	inScale	float	0.001 – ∞	1.0f	
→	inScaleDivisor	float	0.001 – ∞	1.0f	
←	outCoordinateSystem	CoordinateSystem2D&			

Hints

- Pass **inVector** to a computed vector representing the origin of a new coordinate system.
- Optionally set **inAngle** to define the rotation.
- Optionally set **inScale** and **inScaleDivisor** to obtain a custom scale.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Also in AVL Lite

EllipseThroughFourPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes an ellipse passing through four noncollinear points.

Syntax

```
void avl::EllipseThroughFourPoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 const avl::Point2D& inPoint3,
 const avl::Point2D& inPoint4,
 atl::Conditional<avl::Ellipse2D>& outEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		
→	inPoint2	const Point2D&		
→	inPoint3	const Point2D&		
→	inPoint4	const Point2D&		
←	outEllipse	Conditional<Ellipse2D>&		Ellipse passing through the specified points; or Nil if the points don't define a proper ellipse.

Also in AVL Lite

EllipseThroughThreePoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes an ellipse passing through three noncollinear points.

Syntax

```
void avl::EllipseThroughThreePoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 const avl::Point2D& inPoint3,
 atl::Conditional<avl::Ellipse2D>& outEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		
→	inPoint2	const Point2D&		
→	inPoint3	const Point2D&		
←	outEllipse	Conditional<Ellipse2D>&		Ellipse passing through the specified points; or Nil if the points are collinear

LineThroughPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a line passing through a point with given angle.

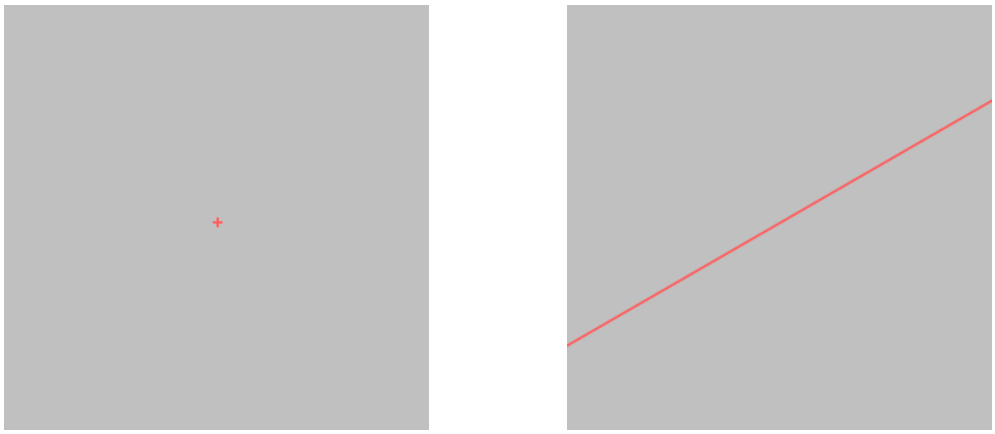
Syntax

```
void avl::LineThroughPoint
(
 const avl::Point2D& inPoint,
 float inAngle,
 avl::Line2D& outLine
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inAngle	float		
←	outLine	Line2D&		

Examples



LineThroughPoint *performed on point,* ***inAngle*** *= 150.*

LineThroughPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a line passing through two distinct points.

Syntax

```
void avl::LineThroughPoints
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 avl::Line2D& outLine
)
```

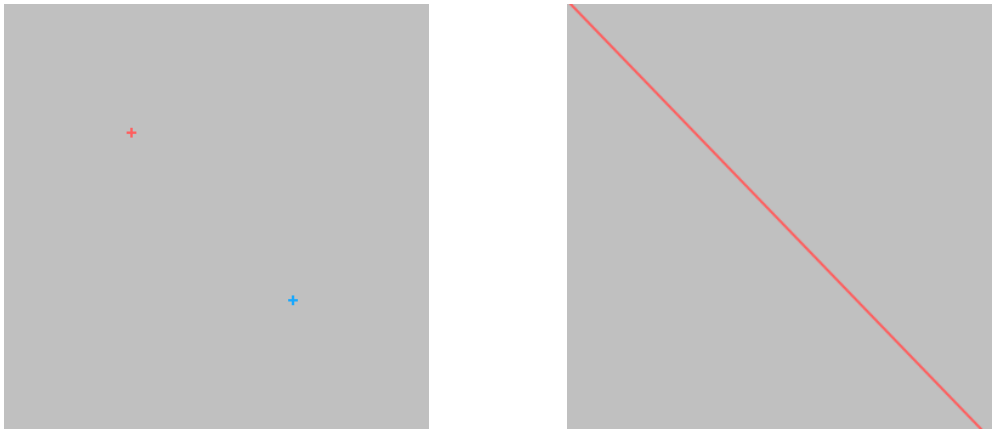
Parameters

	Name	Type	Default	Description
→	inPoint1	const Point2D&		
→	inPoint2	const Point2D&		
←	outLine	Line2D&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when the input points are almost equal.

Examples



LineThroughPoints *performed on two points.*

ProjectPointOnCircle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Projects a point onto a circle.

Syntax

```
void avl::ProjectPointOnCircle
(
 const avl::Point2D& inPoint,
 const avl::Circle2D& inCircle,
 avl::Point2D& outProjectionPoint
)
```

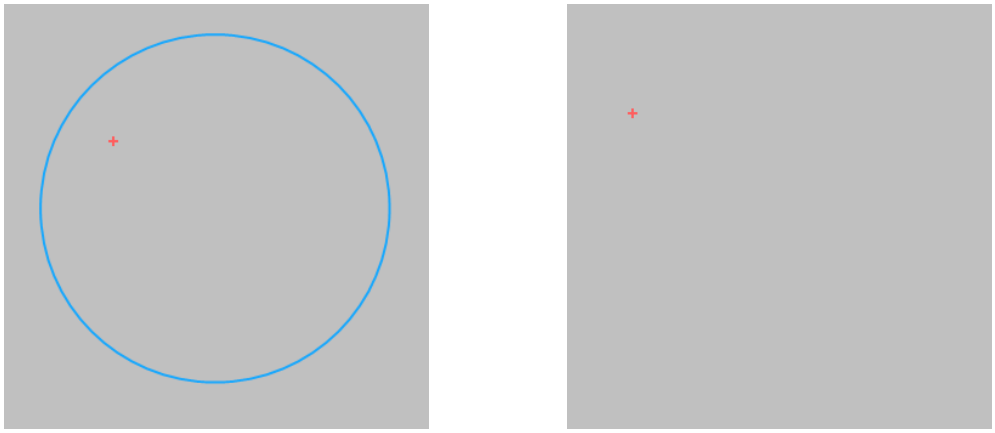
Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inCircle	const Circle2D&		
←	outProjectionPoint	Point2D&		

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when the input point and the center of the input circle are almost equal.

Examples



ProjectPointOnCircle *performed on point and circle.*

ProjectPointOnLine

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Projects a point onto a line.

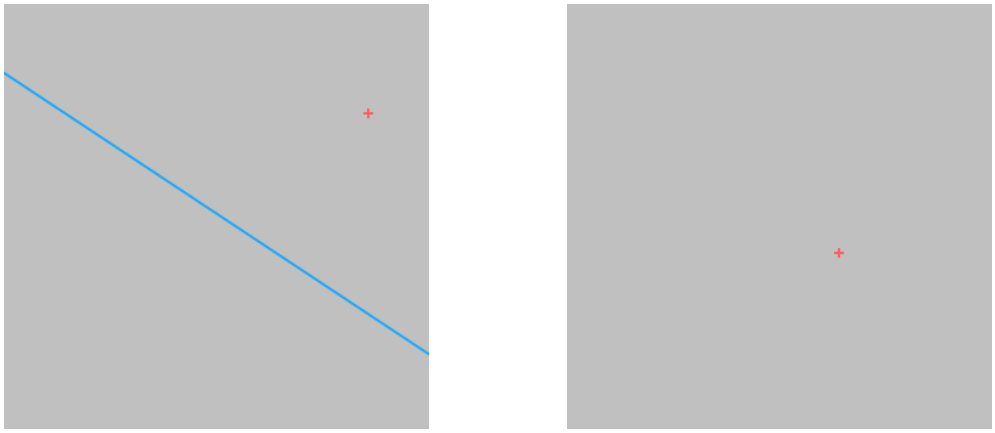
Syntax

```
void avl::ProjectPointOnLine
(
 const avl::Point2D& inPoint,
 const avl::Line2D& inLine,
 avl::Point2D& outProjectionPoint,
 float& outSignedDistance = atl::Dummy<float>()
)
```

Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inLine	const Line2D&		
←	outProjectionPoint	Point2D&		
←	outSignedDistance	float&	Dummy<float> ()	

Examples



***ProjectPointOnLine** performed on point and line.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in ProjectPointOnLine.

ProjectPointsOnCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Projects points onto a circle.

Syntax

```
void avl::ProjectPointsOnCircle
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Circle2D& inCircle,
 atl::Array<avl::Point2D>& outProjectionPoints,
 atl::Conditional<avl::Arc2D>& outProjectionArc
)
```

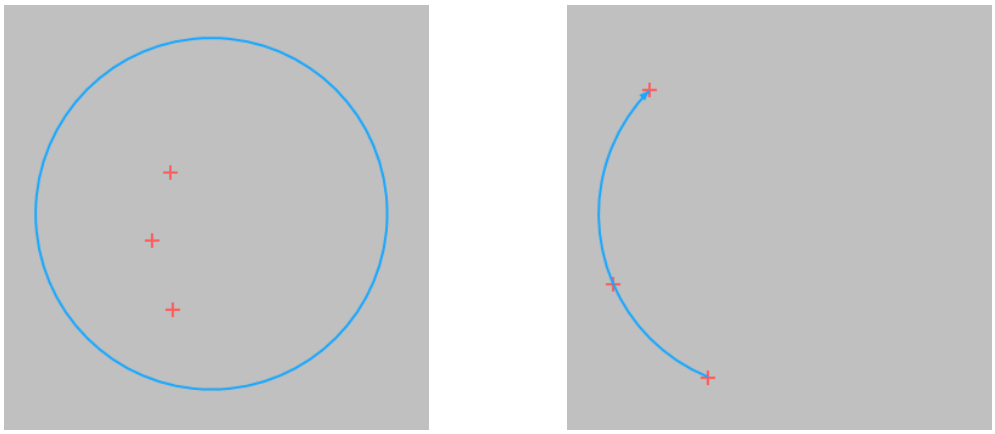
Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Points to be projected
→	inCircle	const Circle2D&		Circle the points will be projected on
←	outProjectionPoints	Array<Point2D>&		Projected points
←	outProjectionArc	Conditional<Arc2D>&		Arc containing the projected points

Description

Note that because of inaccuracies of floating-point arithmetic, some geometric operations (including this one) may lead to unpredictable results for degenerated cases. In this filter such a case occurs when an input point and the center of the input circle are almost equal.

Examples



ProjectPointsOnCircle *performed on points and circle.*

ProjectPointsOnLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Projects points onto a line.

Syntax

```
void avl::ProjectPointsOnLine
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Line2D& inLine,
 atl::Array<avl::Point2D>& outProjectionPoints,
 atl::Optional<atl::Conditional<avl::Segment2D>&> outProjectionSegment = atl::NIL,
 float& outMeanDistance = atl::Dummy<float>()
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inLine	const Line2D&		
←	outProjectionPoints	Array<Point2D>&		
←	outProjectionSegment	Optional<Conditional<Segment2D>&>	NIL	
←	outMeanDistance	float&	Dummy<float>()	

Optional Outputs

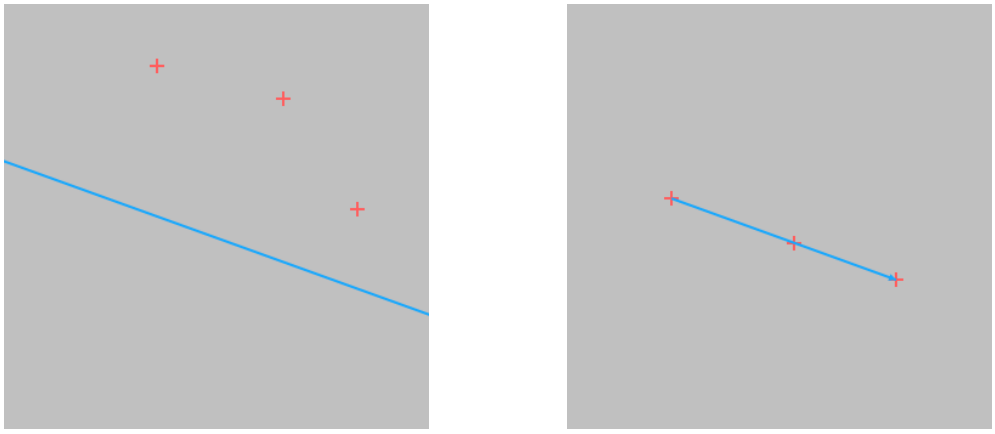
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionSegment**.

Read more about Optional Outputs.

Description

The orientation of the resulting **outProjectionSegment** is always between 0 and 180 degrees.

Examples



ProjectPointsOnLine *performed on points and line.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in ProjectPointsOnLine.

SplitRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Splits the rectangle into two along the direction.

Syntax

```
void avl::SplitRectangle
(
 const avl::Rectangle2D& inRectangle,
 const avl::SplitDirection::Type inSplitDirection,
 avl::Rectangle2D& outRectangle1,
 avl::Rectangle2D& outRectangle2
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		
→	inSplitDirection	const SplitDirection::Type		
←	outRectangle1	Rectangle2D&		
←	outRectangle2	Rectangle2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown split direction in SplitRectangle.

VectorBetweenPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a vector representing distance from one point to another.

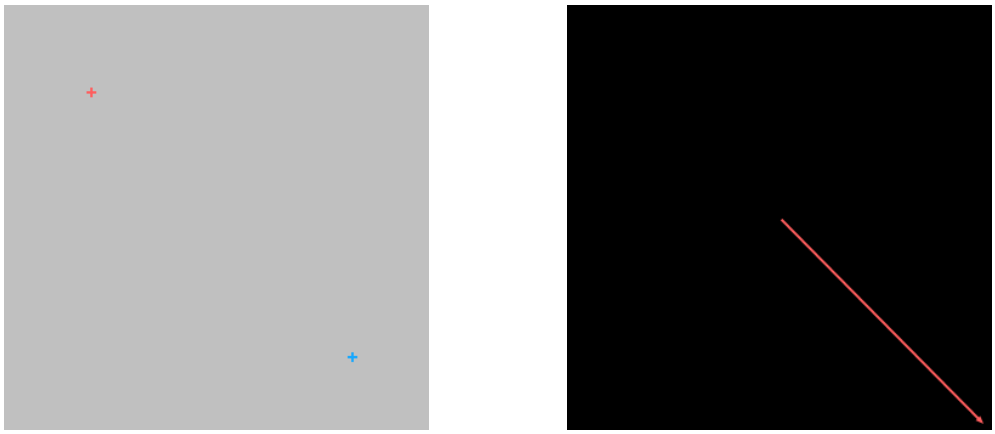
Syntax

```
void avl::VectorBetweenPoints
(
 const avl::Point2D& inFrom,
 const avl::Point2D& inTo,
 avl::Vector2D& outVector
)
```

Parameters

	Name	Type	Default	Description
→	inFrom	const Point2D&		
→	inTo	const Point2D&		
←	outVector	Vector2D&		

Examples



VectorBetweenPoints *performed on two points.*

64. Geometry 3D Constructions

Table of content:

- CircleThroughPoints3D
- LineThroughPoint3D
- LineThroughPoints3D
- PlaneThroughLineAndPoint3D
- PlaneThroughPoints3D
- ProjectPointsOnLine3D
- VectorBetweenPoints3D

CircleThroughPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a circle in 3D passing through three noncollinear 3D points.

Syntax

```
void avl::CircleThroughPoints3D
(
 const avl::Point3D& inPoint1,
 const avl::Point3D& inPoint2,
 const avl::Point3D& inPoint3,
 atl::Conditional<avl::Circle3D>& outCircle3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point3D&		
→	inPoint2	const Point3D&		
→	inPoint3	const Point3D&		
←	outCircle3D	Conditional<Circle3D>&		Circle in 3D passing through the specified 3D points; or Nil if the points are collinear

LineThroughPoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a line in 3D passing through a point with given direction.

Syntax

```
void avl::LineThroughPoint3D
(
 const avl::Point3D& inPoint3D,
 const avl::Vector3D& inDirectionVector,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		A point on the created line
→	inDirectionVector	const Vector3D&		Desired direction of the line
←	outLine3D	Line3D&		The resulting line in 3D

LineThroughPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a line in 3D passing through two points.

Syntax

```
void avl::LineThroughPoints3D
(
 const avl::Point3D& inPoint1,
 const avl::Point3D& inPoint2,
 avl::Line3D& outLine3D
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point3D&		A point on the created line
→	inPoint2	const Point3D&		Another point on the created line
←	outLine3D	Line3D&		The resulting line in 3D

PlaneThroughLineAndPoint3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a plane passing through a line and a point in 3D.

Syntax

```
void avl::PlaneThroughLineAndPoint3D
(
 const avl::Line3D& inLine3D,
 const avl::Point3D& inPoint3D,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inPoint3D	const Point3D&		
←	outPlane	Plane3D&		

PlaneThroughPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a plane passing through three distinct points in 3D.

Syntax

```
void avl::PlaneThroughPoints3D
(
 const avl::Point3D& inPoint1,
 const avl::Point3D& inPoint2,
 const avl::Point3D& inPoint3,
 avl::Plane3D& outPlane
)
```

Parameters

	Name	Type	Default	Description
→	inPoint1	const Point3D&		
→	inPoint2	const Point3D&		
→	inPoint3	const Point3D&		
←	outPlane	Plane3D&		

ProjectPointsOnLine3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Projects points onto a line.

Syntax

```
void avl::ProjectPointsOnLine3D
(
 const atl::Array<avl::Point3D>& inPoints,
 const avl::Line3D& inLine,
 atl::Array<avl::Point3D>& outProjectionPoints,
 atl::Optional<atl::Conditional<avl::Segment3D>&> outProjectionSegment = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
→	inLine	const Line3D&		
←	outProjectionPoints	Array<Point3D>&		
←	outProjectionSegment	Optional<Conditional<Segment3D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outProjectionSegment**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line in inLine in ProjectPointsOnLine3D.

VectorBetweenPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes a vector representing distance from one point in 3D to another.

Syntax

```
void avl::VectorBetweenPoints3D
(
 const avl::Point3D& inFrom,
 const avl::Point3D& inTo,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Default	Description
→	inFrom	const Point3D&		
→	inTo	const Point3D&		
←	outVector3D	Vector3D&		

65. Geometry 2D Distance Metrics

Table of content:

- CircleToCircleDistance
- PointSequenceDistances
- PointToArcDistance
- PointToCircleDistance
- PointToLineDistance
- PointToLineDistance_Oriented
- PointToPointDistance
- PointToRectangleDistance
- PointToSegmentDistance
- SegmentToSegmentDistance

CircleToCircleDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between two circles.

Syntax

```
void avl::CircleToCircleDistance
(
 const avl::Circle2D& inCircle1,
 const avl::Circle2D& inCircle2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

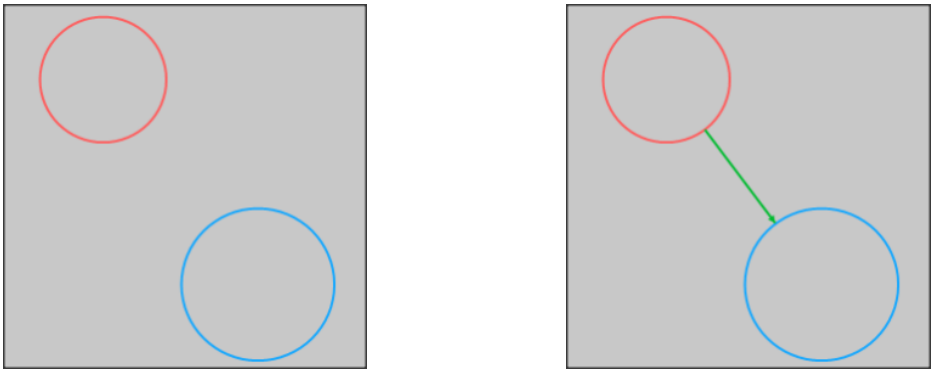
	Name	Type	Range	Default	Description
→	inCircle1	const Circle2D&			
→	inCircle2	const Circle2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



CircleToCircleDistance *performed on two sample circles. The green segment is the value of* ***outConnectingSegment*** *output.*

PointSequenceDistances

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distances between consecutive points of a point sequence.

Syntax

```
void avl::PointSequenceDistances
(
 const atl::Array<avl::Point2D>& inPoints,
 const bool inCyclic,
 float inResolution,
 atl::Array<float>& outDistances,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outConnectingSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			
→	inCyclic	const bool			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistances	Array<float>&			
←	outDistanceSum	Optional<float&>		NIL	
←	outConnectingSegments	Optional<Array<Segment2D>&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**, **outConnectingSegments**.

Read more about Optional Outputs.

PointToArcDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between a point and an arc.

Syntax

```
void avl::PointToArcDistance
(
 const avl::Point2D& inPoint,
 const avl::Arc2D& inArc,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

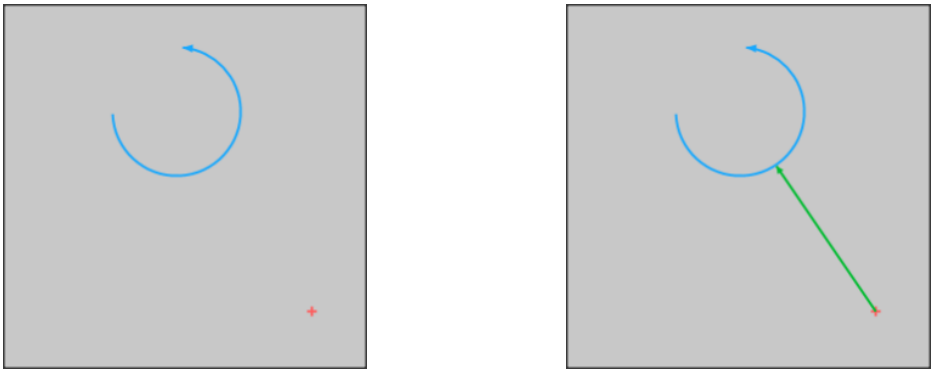
	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inArc	const Arc2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



PointToArcDistance *performed on a sample point and a sample arc. The green segment is the value of* ***outConnectingSegment*** *output.*

PointToCircleDistance

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between a point and a circle.

Syntax

```
void avl::PointToCircleDistance
(
 const avl::Point2D& inPoint,
 const avl::Circle2D& inCircle,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

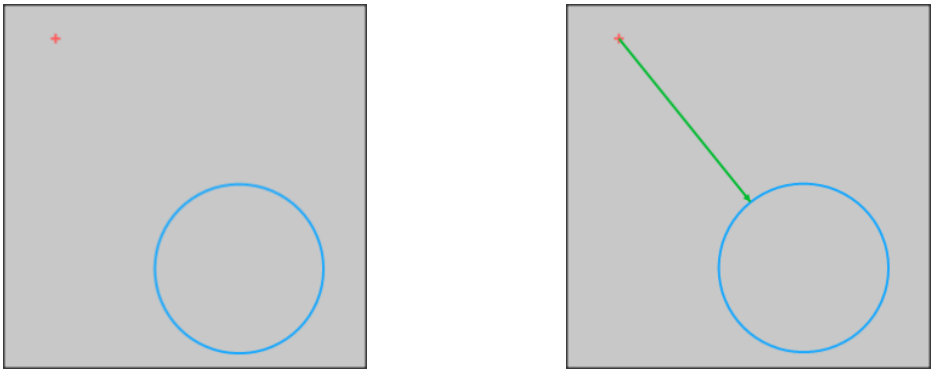
	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inCircle	const Circle2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



PointToCircleDistance *performed on a sample point and a sample circle. The green segment is the value of* ***outConnectingSegment*** *output.*

PointToLineDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between a point and a line.

Syntax

```
void avl::PointToLineDistance
(
 const avl::Point2D& inPoint,
 const avl::Line2D& inLine,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL,
 atl::Optional<float&> outSignedDistance = atl::NIL
)
```

Parameters

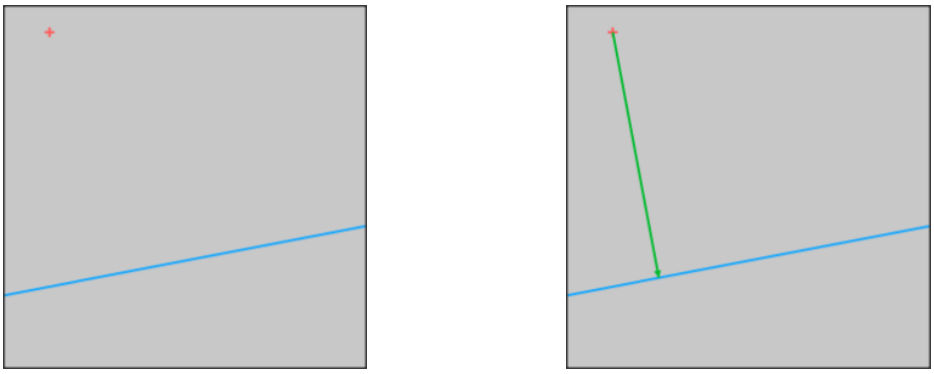
	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inLine	const Line2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	
←	outSignedDistance	Optional<float&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**, **outSignedDistance**.

Read more about Optional Outputs.

Examples



PointToLineDistance *performed on a sample point and a sample line. The green segment is the value of* ***outConnectingSegment*** *output.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in PointToLineDistance.

PointToLineDistance_Oriented

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the signed distance between a point and a line with direction.

Syntax

```
void avl::PointToLineDistance_Oriented
(
 const avl::Point2D& inPoint,
 const avl::Segment2D& inLineSection,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inLineSection	const Segment2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

PointToPointDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between two points.

Syntax

```
void avl::PointToPointDistance
(
 const avl::Point2D& inPoint1,
 const avl::Point2D& inPoint2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

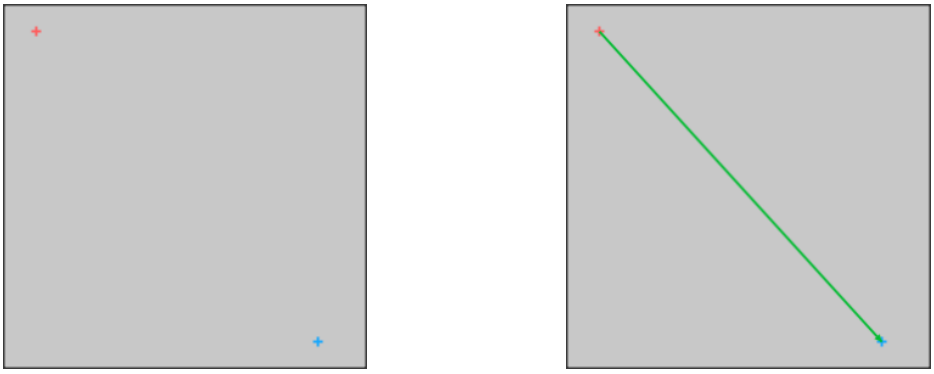
	Name	Type	Range	Default	Description
→	inPoint1	const Point2D&			
→	inPoint2	const Point2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



PointToPointDistance *performed on two sample points. The green segment is the value of* ***outConnectingSegment*** *output.*

PointToRectangleDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between point and rectangle.

Syntax

```
void avl::PointToRectangleDistance
(
 const avl::Point2D& inPoint,
 const avl::Rectangle2D& inRectangle,
 const float inResolution,
 const bool inIsFilled,
 float& outDistance,
 atl::Conditional<avl::Segment2D>& outConnectingSegment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inRectangle	const Rectangle2D&			
→	inResolution	const float	0.0 – ∞	1.0f	Number of real-world units per one pixel
→	inIsFilled	const bool		True	Whether the rectangle is filled inside or not
←	outDistance	float&			
←	outConnectingSegment	Conditional<Segment2D>&			

PointToSegmentDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between a point and a segment.

Syntax

```
void avl::PointToSegmentDistance
(
 const avl::Point2D& inPoint,
 const avl::Segment2D& inSegment,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

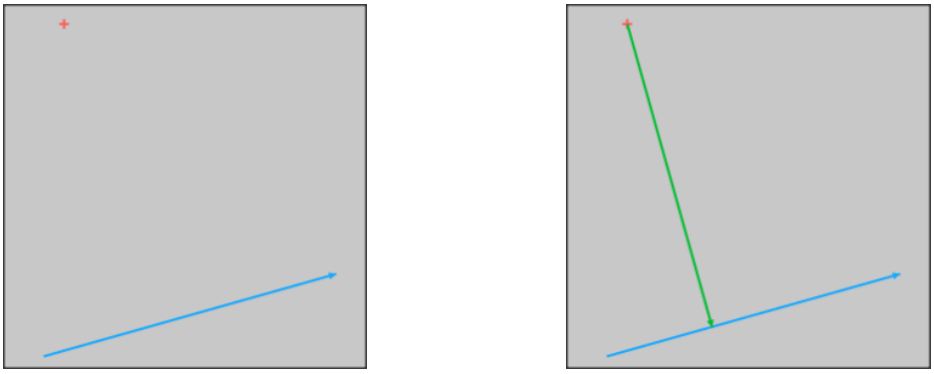
	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inSegment	const Segment2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



PointToSegmentDistance *performed on a sample point and a sample segment. The green segment is the value of* ***outConnectingSegment*** *output.*

SegmentToSegmentDistance

Header: AVL.h
Namespace: avl
Module: FoundationLite

Measures the distance between two segments.

Syntax

```
void avl::SegmentToSegmentDistance
(
 const avl::Segment2D& inSegment1,
 const avl::Segment2D& inSegment2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

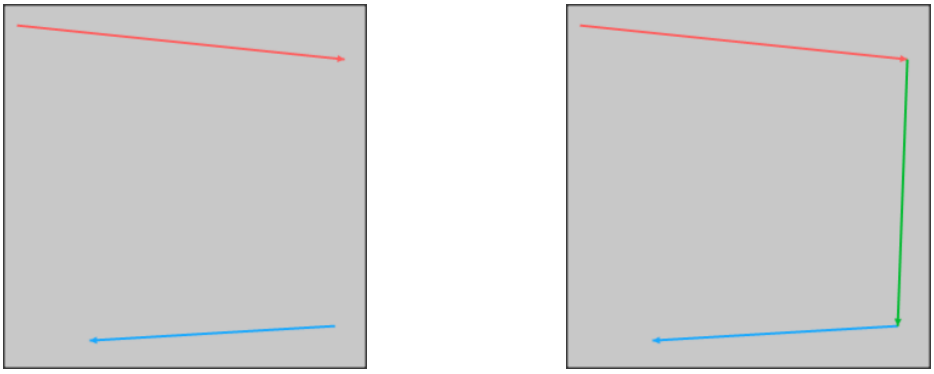
	Name	Type	Range	Default	Description
→	inSegment1	const Segment2D&			
→	inSegment2	const Segment2D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Examples



SegmentToSegmentDistance *performed on two sample segments. The green segment is the value of* ***outConnectingSegment*** *output.*

CircleToPlaneDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between a circle in 3D and a plane.

Syntax

```
void avl::CircleToPlaneDistance3D
(
 const avl::Circle3D& inCircle3D,
 const avl::Plane3D& inPlane,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL,
 atl::Optional<float&> outSignedDistance = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCircle3D	const Circle3D&			
→	inPlane	const Plane3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment3D	Optional<Segment3D&>		NIL	
←	outSignedDistance	Optional<float&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment3D**, **outSignedDistance**.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in CircleToPlaneDistance3D.
DomainError	Indefinite plane on input in CircleToPlaneDistance3D.

LineToLineDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between two lines in 3D.

Syntax

```
void avl::LineToLineDistance3D
(
 const avl::Line3D& inLine1,
 const avl::Line3D& inLine2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLine1	const Line3D&			
→	inLine2	const Line3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment3D	Optional<Segment3D&>		NIL	

Optional Outputs

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in LineToLineDistance3D.

PointSequenceDistances3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distances between consecutive points of a point sequence in 3D.

Syntax

```
void avl::PointSequenceDistances3D
(
 const atl::Array<avl::Point3D>& inPoints,
 const bool inCyclic,
 atl::Array<float>& outDistances,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<avl::Segment3D>&> outConnectingSegments = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point3D>&		
→	inCyclic	const bool		
←	outDistances	Array<float>&		
←	outDistanceSum	Optional<float&>	NIL	
←	outConnectingSegments	Optional<Array<Segment3D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistanceSum**, **outConnectingSegments**.

Read more about Optional Outputs.

PointToCircleDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between a 3D point and a circle in 3D.

Syntax

```
void avl::PointToCircleDistance3D
(
 const avl::Point3D& inPoint3D,
 const avl::Circle3D& inCircle3D,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3D	const Point3D&			
→	inCircle3D	const Circle3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in PointToPlaneDistance3D.

PointToPointDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between two 3D points.

Syntax

```
void avl::PointToPointDistance3D
(
 const avl::Point3D& inPoint1,
 const avl::Point3D& inPoint2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint1	const Point3D&			
→	inPoint2	const Point3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment3D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

PointToSegmentDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between a 3D point and a segment in 3D.

Syntax

```
void avl::PointToSegmentDistance3D
(
 const avl::Point3D& inPoint3D,
 const avl::Segment3D& inSegment3D,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint3D	const Point3D&			
→	inSegment3D	const Segment3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment3D	Optional<Segment3D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment3D**.

Read more about Optional Outputs.

SegmentToPlaneDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between a segment in 3D and a plane.

Syntax

```
void avl::SegmentToPlaneDistance3D
(
 const avl::Segment3D& inSegment3D,
 const avl::Plane3D& inPlane,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL,
 atl::Optional<float&> outSignedDistance = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment3D	const Segment3D&			
→	inPlane	const Plane3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment3D	Optional<Segment3D&>		NIL	
←	outSignedDistance	Optional<float&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment3D**, **outSignedDistance**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SegmentToPlaneDistance3D.

SegmentToSegmentDistance3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Measures the distance between two segments in 3D.

Syntax

```
void avl::SegmentToSegmentDistance3D
(
 const avl::Segment3D& inSegment1,
 const avl::Segment3D& inSegment2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment3D&> outConnectingSegment3D = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment1	const Segment3D&			
→	inSegment2	const Segment3D&			
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment3D	Optional<Segment3D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment3D**.

67. Path Classification

Table of content:

- ClassifyPaths
- GetMaximumPath
- GetMaximumPath_OrNil
- GetMinimumPath
- GetMinimumPath_OrNil
- SelectClosedPaths
- SelectInnerPaths
- SelectOpenPaths
- SelectOuterPaths
- SortPaths

ClassifyPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits the paths of the input array - in accordance to the relation between computed feature values and the specified range.

Applications: Use this filter when you have an array of paths and you want to select some of them for further processing.

Syntax

```
void avl::ClassifyPaths
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFilter::Type inPathFilter,
 avl::PathFeature::Type inFeature,
 atl::Optional<float> inMinimum,
 atl::Optional<float> inMaximum,
 atl::Optional<atl::Array<avl::Path>&> outAccepted,
 atl::Optional<atl::Array<avl::Path>&> outRejected = atl::NIL,
 atl::Optional<atl::Array<avl::Path>&> outBelow = atl::NIL,
 atl::Optional<atl::Array<avl::Path>&> outAbove = atl::NIL,
 atl::Optional<atl::Array<float>&> outValues = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inPathFilter	PathFilter::Type		Determines which paths will take part in computation
→	inFeature	PathFeature::Type		Path feature value to be computed
→	inMinimum	Optional<float>	NIL	Lowest value of the range
→	inMaximum	Optional<float>	NIL	Highest value of the range
←	outAccepted	Optional<Array<Path>&>		Paths with feature values matching the range
←	outRejected	Optional<Array<Path>&>	NIL	Paths with feature values outside the range
←	outBelow	Optional<Array<Path>&>	NIL	Paths with feature values lower than inMinimum
←	outAbove	Optional<Array<Path>&>	NIL	Paths with feature values higher than inMaximum
←	outValues	Optional<Array<float>&>	NIL	Computed feature values

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAccepted**, **outRejected**, **outBelow**, **outAbove**, **outValues**.

Read more about Optional Outputs.

Description

The filter accepts an array of paths and splits it into output arrays, depending on how each of the computed feature values fits the (**inMinimum**, **inMaximum**) range.

- Paths corresponding to feature values lower than **inMinimum** are passed onto **outBelow** and **outRejected**.
- Paths corresponding to feature values that fit closed range (**inMinimum**, **inMaximum**) are passed onto **outAccepted**.
- Paths corresponding to feature values higher than **inMaximum** are passed onto **outAbove** and **outRejected**.

In the special case of **inMinimum** being greater than **inMaximum**, first matching condition is applied, which means that objects corresponding to values higher than **inMaximum** and lower than **inMinimum** are passed onto **outBelow**.

Paths can be filtered before classification. One can process all paths, only open or only closed ones, depending on value of **inPathFilter** input.

To learn about possible features to classify paths, one should see PathFeature documentation. To know details about particular feature, corresponding filter article should be read.

Hints

- Pass an array of paths to the **inPaths** input.
- Using the **inFeature** input select a feature that well separates the interesting objects.
- Using the **inPathFilter** input you can also separate only closed or only open paths.
- Set the range of **inMinimum** and **inMaximum** to define the accepted objects. Refer to the **outValues** output to see the feature values for all input objects.

See Also

- ClassifyByRange – Separates the elements of the input array into three output arrays, depending on whether the related values fall below, into or above the specified range.
- GetMaximumPath – Returns the path from the input array that corresponds to the largest computed feature value.
- GetMinimumPath – Returns the path from the input array that corresponds to the smallest computed feature value.
- SortPaths – Changes the order of paths from the input array according to an ascending/descending sequence of their computed feature values.
- SelectInnerPaths – Selects paths which are visible from a point.
- SelectOuterPaths – Selects paths which do not obstruct visibility of other paths from a point.

GetMaximumPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the path from the input array that corresponds to the largest computed feature value.

Applications: Use this filter when you have an array of paths and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMaximumPath
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFeature::Type inFeature,
 avl::Path& outPath,
 atl::Optional<float&> outValue = atl::NIL,
 atl::Optional<int&> outIndex = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inFeature	PathFeature::Type		Path feature value to be computed
←	outPath	Path&		Output path
←	outValue	Optional<float&>	NIL	Computed feature value of the output path
←	outIndex	Optional<int&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outValue**, **outIndex**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path array on input in GetMaximumPath.

GetMaximumPath_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the path from the input array that corresponds to the largest computed feature value; returns NIL if the array or any path inside it is empty.

Applications: Use this filter when you have an array of paths and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMaximumPath_OrNil
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFeature::Type inFeature,
 atl::Conditional<avl::Path>& outPath,
 atl::Conditional<float>& outValue,
 atl::Conditional<int>& outIndex
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inFeature	PathFeature::Type		Path feature value to be computed
←	outPath	Conditional<Path>&		Output path
←	outValue	Conditional<float>&		Computed feature value of the output path
←	outIndex	Conditional<int>&		

GetMinimumPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the path from the input array that corresponds to the smallest computed feature value.

Applications: Use this filter when you have an array of paths and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMinimumPath
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFeature::Type inFeature,
 avl::Path& outPath,
 atl::Optional<float&> outValue = atl::NIL,
 atl::Optional<int&> outIndex = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inFeature	PathFeature::Type		Path feature value to be computed
←	outPath	Path&		Output path
←	outValue	Optional<float&>	NIL	Computed feature value of the output path
←	outIndex	Optional<int&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outValue**, **outIndex**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path array on input in GetMinimumPath.

GetMinimumPath_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the path from the input array that corresponds to the smallest computed feature value; returns NIL if the array or any path inside it is empty.

Applications: Use this filter when you have an array of paths and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMinimumPath_OrNil
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFeature::Type inFeature,
 atl::Conditional<avl::Path>& outPath,
 atl::Conditional<float>& outValue,
 atl::Conditional<int>& outIndex
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inFeature	PathFeature::Type		Path feature value to be computed
←	outPath	Conditional<Path>&		Output path
←	outValue	Conditional<float>&		Computed feature value of the output path
←	outIndex	Conditional<int>&		

SelectClosedPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects paths which are closed.

Syntax

```
void avl::SelectClosedPaths
(
 const atl::Array<avl::Path>& inPaths,
 atl::Array<avl::Path>& outClosedPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
←	outClosedPaths	Array<Path>&		Paths classified as closed

SelectInnerPaths

Header: AVL.h
Namespace: avl
Module: FoundationPro

Selects paths which are visible from a point.

Syntax

```
void avl::SelectInnerPaths
(
 const atl::Array<avl::Path>& inPaths,
 const avl::Point2D& inCenterPoint,
 float inTolerance,
 atl::Array<avl::Path>& outInnerPaths
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPaths	const Array<Path>&			Input paths from which the inner ones will be selected
→	inCenterPoint	const Point2D&			Reference point used to determine path visibility
→	inTolerance	float	0.0 – 1.0	0.0f	Fraction of the path characteristic points that are allowed to be invisible from the inCenterPoint not rendering the path not-inner
←	outInnerPaths	Array<Path>&			Paths classified as inner

Description

The operation select those paths from the **inPaths** array that are *visible* from **inCenterPoint**.

A point is *visible* iff the segment connecting this point to **inCenterPoint** does not intersect any other path in **inPaths**.

Examples

SelectInnerPaths *run on the sample data with* ***inTolerance*** *= 0.0.*

See Also

- SelectOuterPaths – Selects paths which do not obstruct visibility of other paths from a point.

SelectOpenPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects paths which are open.

Syntax

```
void avl::SelectOpenPaths
(
 const atl::Array<avl::Path>& inPaths,
 atl::Array<avl::Path>& outOpenPaths
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
←	outOpenPaths	Array<Path>&		Paths classified as open

SelectOuterPaths

Header: AVL.h
Namespace: avl
Module: FoundationPro

Selects paths which do not obstruct visibility of other paths from a point.

Syntax

```
void avl::SelectOuterPaths
(
 const atl::Array<avl::Path>& inPaths,
 const avl::Point2D& inCenterPoint,
 float inTolerance,
 atl::Array<avl::Path>& outOuterPaths
)
```

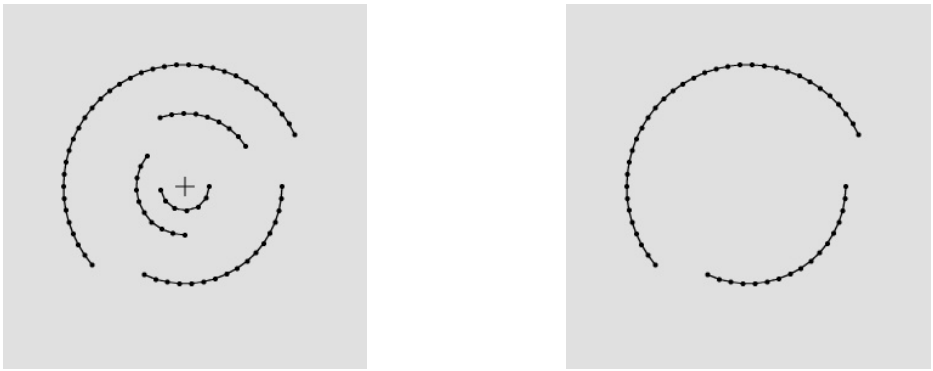
Parameters

	Name	Type	Range	Default	Description
→	inPaths	const Array<Path>&			Input paths from which the outer ones will be selected
→	inCenterPoint	const Point2D&			Reference point used to determine path visibility
→	inTolerance	float	0.0 – 1.0	0.0f	Fraction of the path sections that are allowed to obstruct visibility of other paths not rendering the path not-outer
←	outOuterPaths	Array<Path>&			Paths classified as outer

Description

The operation select those paths from the **inPaths** array that do not obstruct the visibility of any other path. *Visibility* of a characteristic point is obstructed by a path iff the segment connecting this point to **inCenterPoint** intersect the path.

Examples



SelectOuterPaths *run on the sample data with* ***inTolerance*** *= 0.0.*

See Also

- SelectInnerPaths – Selects paths which are visible from a point.

SortPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Changes the order of paths from the input array according to an ascending/descending sequence of their computed feature values.

Syntax

```
void avl::SortPaths
(
 const atl::Array<avl::Path>& inPaths,
 avl::PathFilter::Type inPathFilter,
 avl::PathFeature::Type inFeature,
 avl::SortingOrder::Type inSortingOrder,
 atl::Array<avl::Path>& outSortedPaths,
 atl::Optional<atl::Array<float>&> outSortedValues = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Input paths
→	inPathFilter	PathFilter::Type		Determines which paths will take part in computation
→	inFeature	PathFeature::Type		Path feature value to be computed
→	inSortingOrder	SortingOrder::Type		Sorting order
←	outSortedPaths	Array<Path>&		Paths sorted according to the computed feature values
←	outSortedValues	Optional<Array<float>&>	NIL	Computed feature values

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSortedValues**.

Read more about Optional Outputs.

ClassifyRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits an array of regions according to the selected feature and range.

Applications: Use this filter when you have an array of regions and you want to select some of them for further processing.

Syntax

```
void avl::ClassifyRegions
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 atl::Optional<float> inMinimum,
 atl::Optional<float> inMaximum,
 atl::Optional<atl::Array<avl::Region>&> outAccepted,
 atl::Optional<atl::Array<avl::Region>&> outRejected = atl::NIL,
 atl::Optional<atl::Array<avl::Region>&> outBelow = atl::NIL,
 atl::Optional<atl::Array<avl::Region>&> outAbove = atl::NIL,
 atl::Optional<atl::Array<float>&> outValues = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
→	inMinimum	Optional<float>	NIL	Lowest value of the range
→	inMaximum	Optional<float>	NIL	Highest value of the range
←	outAccepted	Optional<Array<Region>&>		Regions with feature values matching the range
←	outRejected	Optional<Array<Region>&>	NIL	Regions with feature values outside the range
←	outBelow	Optional<Array<Region>&>	NIL	Regions with feature values lower than inMinimum
←	outAbove	Optional<Array<Region>&>	NIL	Regions with feature values higher than inMaximum
←	outValues	Optional<Array<float>&>	NIL	Computed feature values

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAccepted**, **outRejected**, **outBelow**, **outAbove**, **outValues**.

Read more about Optional Outputs.

Description

The filter accepts an array of regions and splits it into output arrays, depending on how each of the computed feature values fits the (**inMinimum**, **inMaximum**) range.

- Regions corresponding to feature values lower than **inMinimum** are passed onto **outBelow** and **outRejected**.
- Regions corresponding to feature values that fit closed range (**inMinimum**, **inMaximum**) are passed onto **outAccepted**.
- Regions corresponding to feature values higher than **inMaximum** are passed onto **outAbove** and **outRejected**.

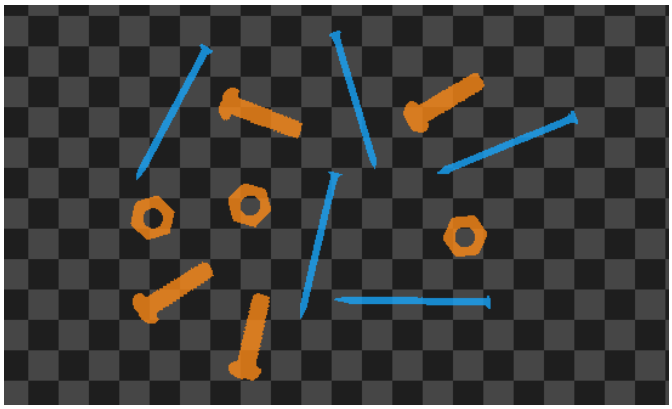
In the special case of **inMinimum** being greater than **inMaximum**, first matching condition is applied, which means that objects corresponding to values higher than **inMaximum** and lower than **inMinimum** are passed onto **outBelow**.

To learn about possible features to classify regions, one should see RegionFeature documentation. To know details about particular feature, corresponding filter article should be read.

Hints

- Pass an array of regions to the **inRegions** input.
- Using the **inFeature** input select a feature that well separates the interesting objects.
- Set the range of **inMinimum** and **inMaximum** to define the accepted objects. Refer to the **outValues** output to see the feature values for all input objects.

Examples



*ClassifyRegions performed with **Elongation** selected as the region feature and **inMaximum** = 10. The blue regions are from **outAccepted** output, the orange ones from **outRejected**.*

See Also

- ClassifyByRange – Separates the elements of the input array into three output arrays, depending on whether the related values fall below, into or above the specified range.
- GetMaximumRegion – Returns the region from the input array that corresponds to the largest computed feature value.
- GetMinimumRegion – Returns the region from the input array that corresponds to the smallest computed feature value.
- SortRegions – Changes the order of regions from the input array according to an ascending/descending sequence of their computed feature values.

GetMaximumRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the region from the input array that corresponds to the largest computed feature value.

Applications: Use this filter when you have an array of regions and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMaximumRegion
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 avl::Region& outRegion,
 atl::Optional<float&> outValue = atl::NIL,
 atl::Optional<int&> outIndex = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
←	outRegion	Region&		Output region
←	outValue	Optional<float&>	NIL	Computed feature value of the output region
←	outIndex	Optional<int&>	NIL	

Optional Outputs

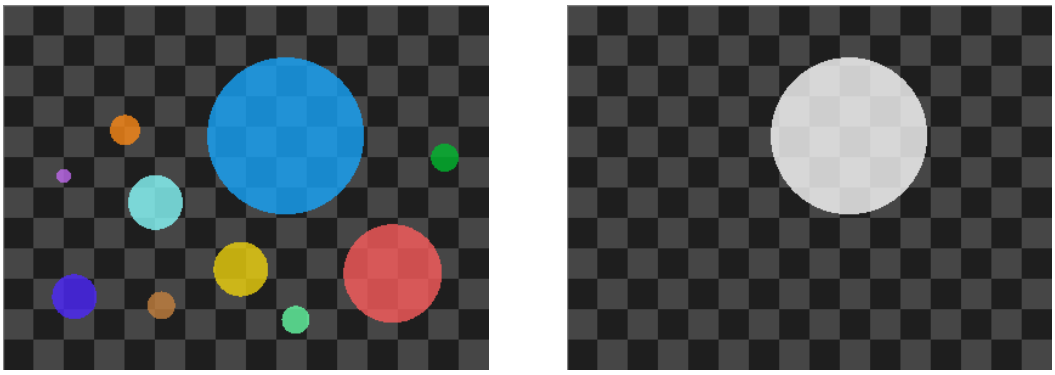
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outValue**, **outIndex**.

Read more about Optional Outputs.

Description

The filter computes the selected feature value for every input region and returns the one for which value is the largest.

Examples



*GetMaximumRegion performed with **Area** as the selected region feature.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region array on input in GetMaximumRegion.

See Also

- GetMinimumRegion – Returns the region from the input array that corresponds to the smallest computed feature value.
- SortRegions – Changes the order of regions from the input array according to an ascending/descending sequence of their computed feature values.
- ClassifyRegions – Splits an array of regions according to the selected feature and range.

GetMaximumRegion_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the region from the input array that corresponds to the largest computed feature value; returns NIL if the array or any region inside it is empty.

Applications: Use this filter when you have an array of regions and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMaximumRegion_OrNil
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 atl::Conditional<avl::Region>& outRegion,
 atl::Conditional<float>& outValue,
 atl::Conditional<int>& outIndex
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
←	outRegion	Conditional<Region>&		Output region
←	outValue	Conditional<float>&		Computed feature value of the output region
←	outIndex	Conditional<int>&		

GetMinimumRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the region from the input array that corresponds to the smallest computed feature value.

Applications: Use this filter when you have an array of regions and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMinimumRegion
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 avl::Region& outRegion,
 atl::Optional<float&> outValue = atl::NIL,
 atl::Optional<int&> outIndex = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
←	outRegion	Region&		Output region
←	outValue	Optional<float&>	NIL	Computed feature value of the output region
←	outIndex	Optional<int&>	NIL	

Optional Outputs

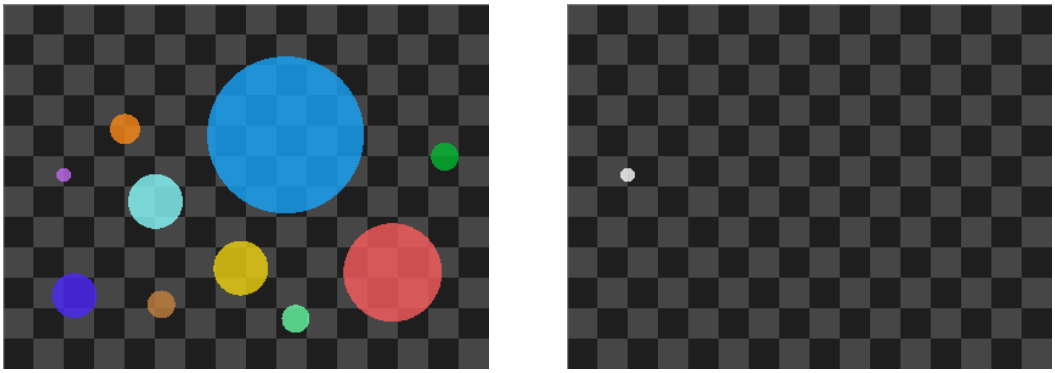
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outValue**, **outIndex**.

Read more about Optional Outputs.

Description

The filter computes the selected feature value for every input region and returns the one for which value is the smallest.

Examples



*GetMinimumRegion performed with **Area** as the selected region feature.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region array on input in GetMinimumRegion.

See Also

- GetMaximumRegion – Returns the region from the input array that corresponds to the largest computed feature value.
- SortRegions – Changes the order of regions from the input array according to an ascending/descending sequence of their computed feature values.
- ClassifyRegions – Splits an array of regions according to the selected feature and range.

GetMinimumRegion_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the region from the input array that corresponds to the smallest computed feature value; returns NIL if the array or any region inside it is empty.

Applications: Use this filter when you have an array of regions and you want to select one of them that best matches some criterion.

Syntax

```
void avl::GetMinimumRegion_OrNil
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 atl::Conditional<avl::Region>& outRegion,
 atl::Conditional<float>& outValue,
 atl::Conditional<int>& outIndex
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
←	outRegion	Conditional<Region>&		Output region
←	outValue	Conditional<float>&		Computed feature value of the output region
←	outIndex	Conditional<int>&		

GroupPathsByRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

For each region returns which paths lie inside of it or intersect with it.

Syntax

```
void avl::GroupPathsByRegions
(
 const atl::Array<avl::Path>& inPaths,
 const atl::Array<avl::Region>& inRegions,
 avl::MatchingCriterion::Type inMatchingCriterion,
 atl::Array<atl::Array<int> >& outGroupedIndices,
 atl::Optional<atl::Array<atl::Array<avl::Path> >&> outGroupedPaths = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		Array of paths that will be classified into multiple groups
→	inRegions	const Array<Region>&		Array of regions that define the groups
→	inMatchingCriterion	MatchingCriterion::Type		Specifies whether a path must fully belong to a group region or if it is enough that it intersects
←	outGroupedIndices	Array<Array<int> >&		Indices of input paths classified into multiple groups
←	outGroupedPaths	Optional<Array<Array<Path> >&>	NIL	Input paths classified into multiple groups

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outGroupedPaths**.

Read more about Optional Outputs.

See Also

- GroupPointsByRegions – For each region returns which points lie inside of it.
- AvsFilter_GetMultipleArrayElements – Extracts multiple elements from an array.

GroupPointsByRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

For each region returns which points lie inside of it.

Syntax

```
void avl::GroupPointsByRegions
(
 const atl::Array<avl::Point2D>& inPoints,
 const atl::Array<avl::Region>& inRegions,
 atl::Array<atl::Array<int> >& outGroupedIndices,
 atl::Optional<atl::Array<atl::Array<avl::Point2D> >&> outGroupedPoints = atl::NIL
)
```

Parameters

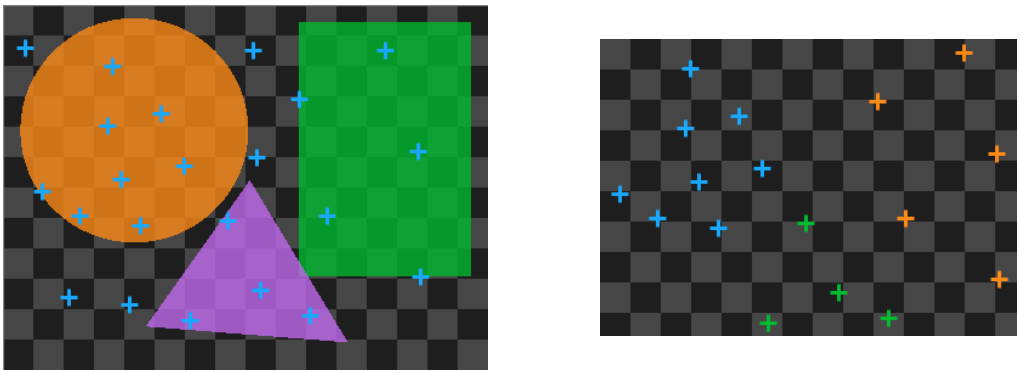
	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
→	inRegions	const Array<Region>&		
←	outGroupedIndices	Array<Array<int> >&		
←	outGroupedPoints	Optional<Array<Array<Point2D> >&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outGroupedPoints**.

Read more about Optional Outputs.

Examples



GroupPointsByRegions performed with three input regions.

See Also

- AvsFilter_GetMultipleArrayElements – Extracts multiple elements from an array.

GroupRegionsByRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

For each region returns which regions lie inside of it or intersect with it.

Syntax

```
void avl::GroupRegionsByRegions
(
 const atl::Array<avl::Region>& inRegions,
 const atl::Array<avl::Region>& inGroupRegions,
 avl::MatchingCriterion::Type inMatchingCriterion,
 atl::Array<atl::Array<int> >& outGroupedIndices,
 atl::Optional<atl::Array<atl::Array<avl::Region> >&> outGroupedRegions = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Array of regions that will be classified into multiple groups
→	inGroupRegions	const Array<Region>&		Array of regions that define the groups
→	inMatchingCriterion	MatchingCriterion::Type		Specifies whether a region must fully belong to a group region or if it is enough that it intersects
←	outGroupedIndices	Array<Array<int> >&		Indices of input regions classified into multiple groups
←	outGroupedRegions	Optional<Array<Array<Region> >&>	NIL	Input regions classified into multiple groups

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outGroupedRegions**.

Read more about Optional Outputs.

InscribeRegionInRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shifts source region so that it is contained in target region.

Syntax

```
void avl::InscribeRegionInRegion
(
 const avl::Region& inTargetRegion,
 const avl::Region& inSourceRegion,
 avl::ShiftType::Type inPossibleShift,
 avl::FitType::Type inFitType,
 atl::Conditional<int>& outShiftX,
 atl::Conditional<int>& outShiftY,
 atl::Conditional<avl::Region>& outShiftedRegion
)
```

Parameters

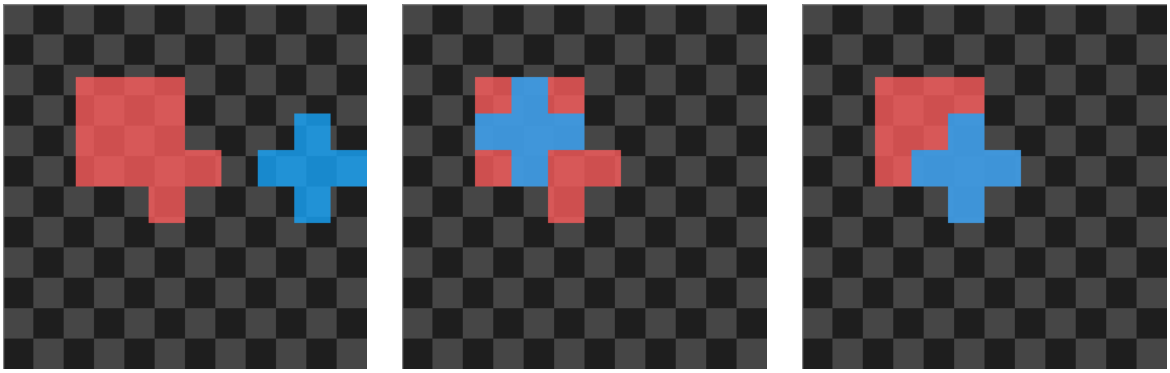
	Name	Type	Default	Description
→	inTargetRegion	const Region&		Region to contain source region
→	inSourceRegion	const Region&		Region to be shifted
→	inPossibleShift	ShiftType::Type		Possible directions of shift
→	inFitType	FitType::Type		Determines if the common border length should be maximized
←	outShiftX	Conditional<int>&		X coordinate of the shift
←	outShiftY	Conditional<int>&		Y coordinate of the shift
←	outShiftedRegion	Conditional<Region>&		Shifted source region

Description

The filter shifts **inSourceRegion** so that it is entirely contained in **inTargetRegion**. When **inFitType** is **FirstFit**, the function returns first shift. With **inFitType** set to **BestFit**, the function chooses from all possible shifts one that maximizes length of common border of target region and shifted source region. Parameter **inPossibleShift** defines directions in which source region should be shifted. Possible values are *Any*, *Vertical*, *Horizontal*.

All return values are conditional. In case appropriate shift exists, **outShiftX** and **outShiftY** define its coordinates. **outShiftedRegion** is **inSourceRegion** translated by vector (outShiftX,outShiftY) and with dimensions of **inTargetRegion**.

Examples



InscribeRegionInRegion *performed on pair of sample regions, shown on the left. Middle image shows inscribed region with* ***inFitType*** *set to FirstFit. Right one corresponds to* ***inFitType*** *equal BestFit.*

Remarks

Setting parameter **inFitType** to *BestFit* results in much higher computational cost.

Errors

List of possible exceptions:

Error type	Description
DomainError	Source region cannot be empty in InscribeRegionInRegion.

See Also

- ErodeRegion_AnyKernel – Performs a morphological erosion on a region using an arbitrary kernel.
- TranslateRegion – Translates a region by a given number of pixels along each axis.

SelectRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Selects regions according to the selected feature and range.

Applications: Use this filter when you have an array of regions and you want to select some of them for further processing. It is slightly faster than ClassifyRegions.

Syntax

```
void avl::SelectRegions
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 atl::Optional<float> inMinimum,
 atl::Optional<float> inMaximum,
 atl::Array<avl::Region>& outAccepted,
 atl::Optional<atl::Array<float>&> outValues = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
→	inMinimum	Optional<float>	NIL	Lowest value of the range
→	inMaximum	Optional<float>	NIL	Highest value of the range
←	outAccepted	Array<Region>&		Regions with feature values matching the range
←	outValues	Optional<Array<float>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outValues**.

Read more about Optional Outputs.

SortRegions

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Changes the order of regions from the input array according to an ascending/descending sequence of their computed feature values.

Syntax

```
void avl::SortRegions
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 avl::SortingOrder::Type inSortingOrder,
 atl::Array<avl::Region>& outSortedRegions,
 atl::Optional<atl::Array<float>&> outSortedValues = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegions	const Array<Region>&		Input regions
→	inFeature	RegionFeature::Type		Region feature value to be computed
→	inSortingOrder	SortingOrder::Type		Sorting order
←	outSortedRegions	Array<Region>&		Regions sorted according to the computed feature values
←	outSortedValues	Optional<Array<float>&>	NIL	Computed feature values

Optional Outputs

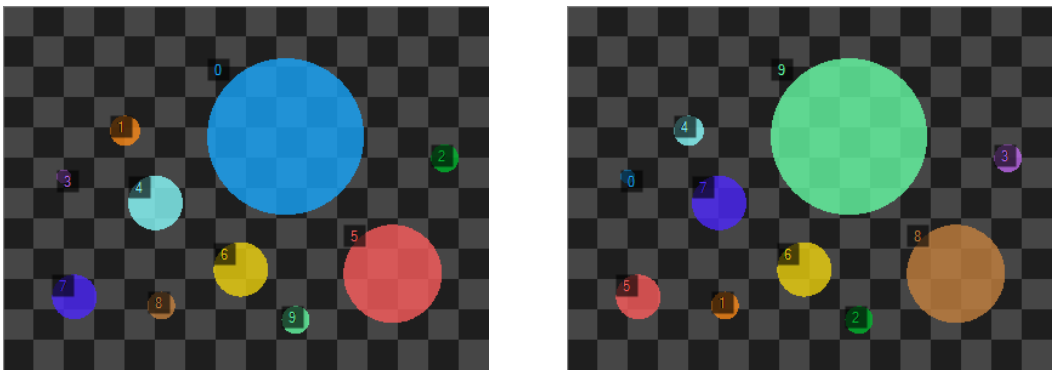
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSortedValues**.

Read more about Optional Outputs.

Description

The filter sorts the array of input regions according to the selected feature values computed for each of them.

Examples



*SortRegions performed with **inFeature** = Area. Input regions are on the left. On the right is the result.*

See Also

- SortArray – Changes the order of the input array elements according to an ascending/descending sequence of the value array.
- GetMaximumRegion – Returns the region from the input array that corresponds to the largest computed feature value.
- GetMinimumRegion – Returns the region from the input array that corresponds to the smallest computed feature value.
- ClassifyRegions – Splits an array of regions according to the selected feature and range.

TestPointArrayInRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests which points lie inside a region.

Syntax

```
void avl::TestPointArrayInRegion
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Region& inRegion,
 atl::Array<bool>& outIsContainedArray,
 atl::Optional<atl::Array<avl::Point2D>&> outPoints = atl::NIL,
 atl::Optional<bool&> outAreAllContained = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Points which will be tested
→	inRegion	const Region&		Input region
←	outIsContainedArray	Array<bool>&		
←	outPoints	Optional<Array<Point2D>&>	NIL	Points that are contained
←	outAreAllContained	Optional<bool&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPoints**, **outAreAllContained**.

Read more about Optional Outputs.

TestPointInRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point lies inside a region.

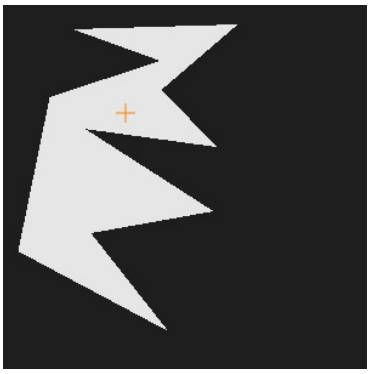
Syntax

```
void avl::TestPointInRegion
(
 const avl::Point2D& inPoint,
 const avl::Region& inRegion,
 bool& outIsContained
)
```

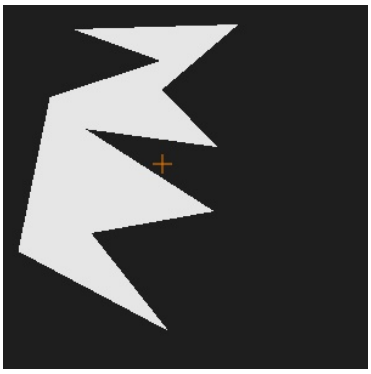
Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inRegion	const Region&		Input region
←	outIsContained	bool&		

Examples



TestPointInRegion *run on the sample data produces the* ***outIsContained*** *= true*



TestPointInRegion *run on the sample data produces the* ***outIsContained*** *= false*

TestRegionEqualTo

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether given regions are equal.

Syntax

```
void avl::TestRegionEqualTo
(
 const avl::Region& inRegion,
 const avl::Region& inReferenceRegion,
 bool& outIsEqual
)
```

Parameters

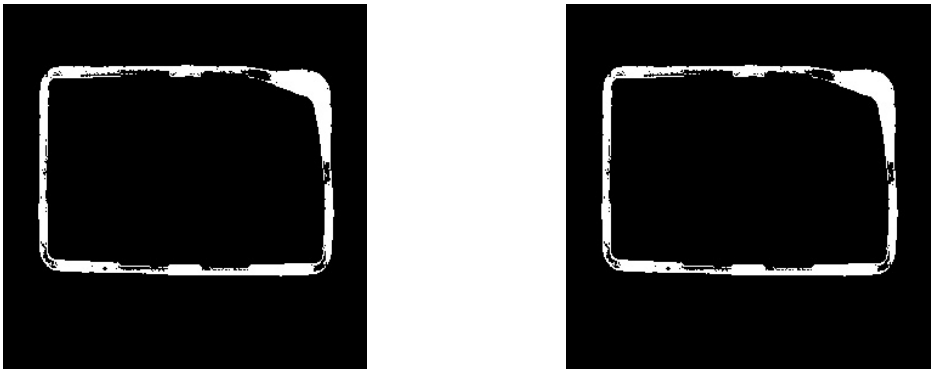
	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inReferenceRegion	const Region&		
←	outIsEqual	bool&		

Description

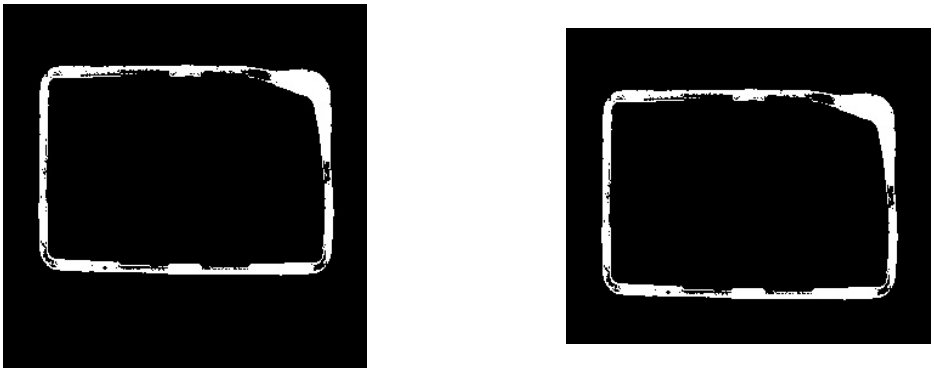
The operation tests whether the **inRegion** is the same region as contained inside **inReferenceRegion**. It means that the resulting **outIsEqual** is set to 'true' if and only if both of the conditions are met:

- **inRegion** and **inReferenceRegion** have the same dimensions
- **inRegion** and **inReferenceRegion** contain the same set of pixels

Examples



TestRegionEqualTo *run with* ***inRegion*** *set to the right region and* ***inReferenceRegion*** *set to the left, computes the* ***outIsEqual*** *= true.*



TestRegionEqualTo *run with* ***inRegion*** *set to the right region and* ***inReferenceRegion*** *set to the left, computes the* ***outIsEqual*** *= false, as dimensions of the regions differ.*

See Also

- TestRegionInRegion – Tests whether a region is contained in another one.

TestRegionInRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether a region is contained in another one.

Syntax

```
void avl::TestRegionInRegion
(
 const avl::Region& inSubregion,
 const avl::Region& inRegion,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inSubregion	const Region&		
→	inRegion	const Region&		Input region
←	outIsContained	bool&		

Description

The operation tests whether the **inSubregion** is contained inside the **inRegion**. The resulting **outIsContained** is set to 'true' if and only if each pixel of **inSubregion** is also included in **inRegion**.

Examples

TestRegionInRegion *run with* ***inSubregion*** *set to the left region and* ***inRegion*** *set to the right, computes the* ***outIsContained*** *= true.*

TestRegionInRegion *run with* ***inSubregion*** *set to the left region and* ***inRegion*** *set to the right, computes the* ***outIsContained*** *= false.*

See Also

- TestRegionEqualTo – Tests whether given regions are equal.

TestRegionIntersectsWith

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether two regions have non-empty intersection.

Syntax

```
void avl::TestRegionIntersectsWith
(
 const avl::Region& inRegion,
 const avl::Region& inReferenceRegion,
 bool& outRegionsIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inReferenceRegion	const Region&		
←	outRegionsIntersect	bool&		

TestRegionUnequalTo

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether given regions are not equal.

Syntax

```
void avl::TestRegionUnequalTo
(
 const avl::Region& inRegion,
 const avl::Region& inReferenceRegion,
 bool& outIsUnequal
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inReferenceRegion	const Region&		
←	outIsUnequal	bool&		

69. Clustering

Table of content:

- ClusterData_KMeans
- ClusterPoints2D
- ClusterPoints2D_SingleLink
- ClusterPoints3D
- FindConnectedComponents

ClusterData_KMeans

Header: AVL.h
Namespace: avl
Module: FoundationPro

Clusters data using KMeans algorithm.

Syntax

```
void avl::ClusterData_KMeans
(
 const atl::Array<atl::Array<float> >& inData,
 const int inClusters,
 const int inMaxIterations,
 const int inSeed,
 const float inTerminationFactor,
 const avl::KMeansClusteringMethod::Type inClusteringMethod,
 avl::Matrix& outCentroids,
 atl::Array<int>& outPointToClusterAssignment,
 float& outDistanceSum
)
```

Parameters

	Name	Type	Range	Default	Description
→	inData	const Array<Array<float> >&			Data set, array of examples
→	inClusters	const int	2 – +∞	2	Number of clusters to extract
→	inMaxIterations	const int	10 – 1000	200	Maximal number of procedure iterations
→	inSeed	const int	0 – ∞	5489	Seed to init random engine
→	inTerminationFactor	const float	1.0 – 2.0	1.5f	Additional factor of procedure stop
→	inClusteringMethod	const KMeansClusteringMethod::Type		KMeansPlusPlus	KMeans variant to use
←	outCentroids	Matrix&			Resulting centroid points in feature space
←	outPointToClusterAssignment	Array<int>&			Array of input point assignments to generated clusters
←	outDistanceSum	float&			Sum of squared distances from points to its respective cluster centroids

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot make more clusters than there is data in input dataset in ClusterData_KMeans.
DomainError	Empty dataset on input in ClusterData_KMeans.
DomainError	Inconsistent number of data coordinates in input dataset in ClusterData_KMeans.

ClusterPoints2D

Header: AVL.h
Namespace: avl
Module: FoundationPro

Clusters 2D points using K Means Clustering method.

Syntax

```
void avl::ClusterPoints2D
(
 const atl::Array<avl::Point2D>& inPoints,
 const int inClusters,
 const int inMaxIterations,
 atl::Optional<int> inSeed,
 const int inRunCount,
 atl::Array<atl::Conditional<atl::Array<avl::Point2D>>>& outClusters,
 atl::Array<atl::Conditional<avl::Point2D>>& outCentroids,
 float& outDistanceSum
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Array of points to cluster
→	inClusters	const int	2 – +∞	2	Number of clusters to extract
→	inMaxIterations	const int	10 – 1000	200	Maximal number of KMeans iterations
→	inSeed	Optional<int>	0 – +∞	5489	Seed used to initialize random number generators
→	inRunCount	const int	1 – +∞	1	Defines how many times the algorithm will be executed
←	outClusters	Array<Conditional<Array<Point2D>>>&			Resulting Point2D clusters
←	outCentroids	Array<Conditional<Point2D>>&			Center of found clusters
←	outDistanceSum	float&			Sum of distance squares from points in array to its respective cluster center

ClusterPoints2D_SingleLink

Header: AVL.h
Namespace: avl
Module: FoundationPro

Clusters data using hierarchical single-link algorithm.

Syntax

```
void avl::ClusterPoints2D_SingleLink
(
 const atl::Array<avl::Point2D>& inPoints,
 const atl::Optional<int> inClusters,
 const atl::Optional<float> inMaxDistance,
 atl::Array<atl::Array<avl::Point2D>>& outClusters
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Array of points to cluster
→	inClusters	const Optional<int>	2 – +∞	NIL	Number of clusters to extract
→	inMaxDistance	const Optional<float>	0.0 – ∞	NIL	Maximum distance between two closest points in a cluster
←	outClusters	Array<Array<Point2D>>&			Resulting Point2D clusters

Remarks

If input parameter **inClusters** is not set, number of clusters is determined in the following way:

- if **inMaxDistance** is set then every two points of mutual distance smaller or equal to **inMaxDistance** belong to one cluster;
- if **inMaxDistance** is not set then an array of sorted edges' lengths of minimum spanning tree of **inPoints** is determined and a pair of two subsequent elements which makes a maximum difference is found. Maximum distance is defined as the smaller element of such a pair.
  In other words number of clusters is the number of vertical lines in the dendrogram cut by a horizontal line that can transverse the maximum distance vertically without intersecting a cluster.

Errors

List of possible exceptions:

Error type	Description
DomainError	Desired number of clusters is greater than inPoints size in ClusterPoints2D_SingleLink.
DomainError	Filter input inPoints is empty in ClusterPoints2D_SingleLink.
DomainError	Too big inPoints array in ClusterPoints2D_SingleLink.

See Also

- ClusterPoints2D – Clusters 2D points using K Means Clustering method.

ClusterPoints3D

Header: AVL.h
Namespace: avl
Module: FoundationPro

Clusters 3D points using K Means Clustering method.

Syntax

```
void avl::ClusterPoints3D
(
 const atl::Array<avl::Point3D>& inPoints,
 const int inClusters,
 const int inMaxIterations,
 atl::Optional<int> inSeed,
 const int inRunCount,
 atl::Array<atl::Conditional<atl::Array<avl::Point3D>>>& outClusters,
 atl::Array<atl::Conditional<avl::Point3D>>& outCentroids,
 float& outDistanceSum
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point3D>&			Array of points to cluster
→	inClusters	const int	2 – +∞	2	Number of clusters to extract
→	inMaxIterations	const int	10 – 1000	200	Maximal number of KMeans iterations
→	inSeed	Optional<int>	0 – +∞	5489	Seed used to initialize random number generators
→	inRunCount	const int	1 – +∞	1	Defines how many times the algorithm will be executed
←	outClusters	Array<Conditional<Array<Point3D>>>&			Resulting Point3D clusters
←	outCentroids	Array<Conditional<Point3D>>&			Center of found clusters
←	outDistanceSum	float&			Sum of distance squares from points in array to its respective cluster center

FindConnectedComponents

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds connected components in a graph given as set of bidirectional connections.

Syntax

```
void avl::FindConnectedComponents
(
 const atl::Array<atl::Array<int> >& inConnections,
 atl::Array<atl::Array<int> >& outComponents,
 atl::Array<int>& outElementLabels,
 bool& outFound = atl::Dummy<bool>()
)
```

Parameters

	Name	Type	Default	Description
→	inConnections	const Array<Array<int> >&		List of connections for each element
←	outComponents	Array<Array<int> >&		List of input element indices for each connected component
←	outElementLabels	Array<int>&		Index of a component for each input element
←	outFound	bool&	Dummy<bool>()	

70. Image Metrics

Table of content:

ColorDistance

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two pixels using chromatic and non-chromatic information. Assumes RGB color space.

Applications: Color comparison insensitive to changes of illumination.

Syntax

```
void avl::ColorDistance
(
 const avl::Pixel& inPixelA,
 const avl::Pixel& inPixelB,
 float inChromaAmount,
 float& outDistance
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPixelA	const Pixel&			
→	inPixelB	const Pixel&			
→	inChromaAmount	float	0.0 – 1.0	0.7f	Proportion of chromatic information in distance computation
←	outDistance	float&			

Description

The operation computes the distance between two pixels.

The distance between pixels is computed using two measures:

- Value distance – the difference between average channel values
- Chromatic distance – euclidean distance between pixels normalized to the same value level

The resulting distance is computed as a weighted average of these two values, parameter **inChromaAmount** (0.0 – 1.0) being the weight of the chromatic distance, and 1 – **inChromaAmount** being the weight of the value distance.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Each pixel component must be nonnegative in ColorDistance.

See Also

- ColorDistanceImage – Compares each pixel with the specified color using chromatic and non-chromatic information.

ColorDistanceImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares each pixel with the specified color using chromatic and non-chromatic information.

Applications: Color analysis insensitive to changes of illumination.

Syntax

```
void avl::ColorDistanceImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Pixel& inRgbColor,
 float inChromaAmount,
 avl::Image& outValueImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Unsigned color image used in comparison
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inRgbColor	const Pixel&			Color to compare the image to
→	inChromaAmount	float	0.0 – 1.0	0.7f	Proportion of chromatic information in distance computation
←	outValueImage	Image&			Unsigned image of distances

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 2×uint8, 3×uint8, 4×uint8.

Read more about pixel formats in Image documentation.

Description

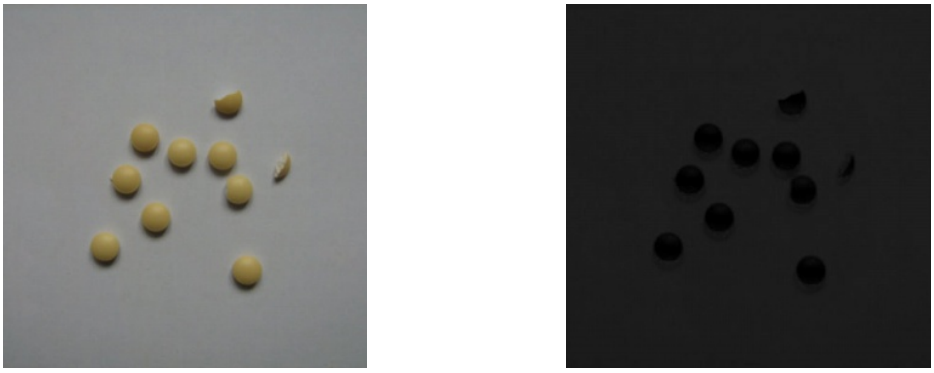
The operation computes the distance between each pixel of **inImage** and a specified color, presenting result as a monochromatic image. Input image should be in RGB color space.

The distance between pixels is computed using two measures:

- Value distance – the difference between average channel values
- Chromatic distance – euclidean distance between pixels normalized to the same value level

The resulting distance is computed as a weighted average of these two values, parameter **inChromaAmount** (0.0 – 1.0) being the weight of the chromatic distance, and 1 – **inChromaAmount** being the weight of the value distance.

Examples



ColorDistanceImage *run with* ***inRgbColor*** *=* , ***inChromaAmount*** *= 0.8*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Invalid image Depth in ColorDistanceImage.
DomainError	Not supported inImage pixel format in ColorDistanceImage. Supported formats: 1xUInt8, 2xUInt8, 3xUInt8, 4xUInt8.
RuntimeError	Each pixel component of inRgbColor must be nonnegative in ColorDistanceImage.

See Also

- ColorDistance – Compares two pixels using chromatic and non-chromatic information. Assumes RGB color space.
- ThresholdToRegion_Color – Creates a region containing image pixels with values close to the given color.
- ThresholdImage_Color – Transforms each pixel value to maximum or minimum depending on the distance from a given color.

ColorDistance_CIE76

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two pixels using CIE76 delta E. Assumes RGB color space.

Syntax

```
void avl::ColorDistance_CIE76
(
 const avl::Pixel& inPixelA,
 const avl::Pixel& inPixelB,
 float& outDistance
)
```

Parameters

	Name	Type	Default	Description
→	inPixelA	const Pixel&		
→	inPixelB	const Pixel&		
←	outDistance	float&		

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Each pixel component must be nonnegative in ColorDistance_CIE76.

ColorDistance_CIE94

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two pixels using CIE94 delta E. Assumes RGB color space.

Syntax

```
void avl::ColorDistance_CIE94
(
 const avl::Pixel& inPixelA,
 const avl::Pixel& inPixelB,
 const float inKL,
 const float inKC,
 const float inKH,
 const float inK1,
 const float inK2,
 float& outDistance
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPixelA	const Pixel&			
→	inPixelB	const Pixel&			
→	inKL	const float	0.0 – ∞	1.0f	The luminance weighting factor (best to use 1.0 for graphic arts and 2.0 for textiles)
→	inKC	const float	0.0 – ∞	1.0f	The chroma weighting factor (usually 1.0)
→	inKH	const float	0.0 – ∞	1.0f	The hue weighting factor (usually 1.0)
→	inK1	const float	0.0 – 1.0	0.045f	The secondary chroma weighting factor (best to use 0.045 for graphic arts and 0.048 for textiles)
→	inK2	const float	0.0 – 1.0	0.015f	The secondary luminance weighting factor (best to use 0.015 for graphic arts and 0.014 for textiles)
←	outDistance	float&			

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Each pixel component must be nonnegative in ColorDistance_CIE94.

ColorDistance_CIEDE2000

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two pixels using CIEDE2000 delta E. Assumes RGB color space.

Syntax

```
void avl::ColorDistance_CIEDE2000
(
 const avl::Pixel& inPixelA,
 const avl::Pixel& inPixelB,
 const float inKL,
 const float inKC,
 const float inKH,
 float& outDistance
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPixelA	const Pixel&			
→	inPixelB	const Pixel&			
→	inKL	const float	0.0 – ∞	1.0f	The luminance weighting factor
→	inKC	const float	0.0 – ∞	1.0f	The chroma weighting factor
→	inKH	const float	0.0 – ∞	1.0f	The hue weighting factor
←	outDistance	float&			

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Each pixel component must be nonnegative in ColorDistance_CIEDE2000.

CompareImages

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two images tile by tile using one of several available methods.

Syntax

```
void avl::CompareImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 avl::CompareMeasure::Type inMeasure,
 int inTileSize,
 int inDensity,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inMeasure	CompareMeasure::Type		DSSIM	
→	inTileSize	int	1 – ∞	25	
→	inDensity	int	1 – ∞		
←	outImage	Image&			Output image

Description

The operation compares two images tile by tile using one of the following methods:

- Value – Sum of absolute differences divided by tile area
- NCC – Normalized cross-correlation
- DSSIM – Structural dissimilarity

Errors

List of possible exceptions:

Error type	Description
DomainError	Formats of input images differ in CompareImages.
DomainError	Images sizes are not equal in CompareImages.
DomainError	Not supported measure type in CompareImages.

See Also

- ColorDistanceImage – Compares each pixel with the specified color using chromatic and non-chromatic information.

CompareImages_CVG

Header: AVL.h
Namespace: avl
Module: FoundationPro

Compares two images tile by tile using one of several available methods.

Syntax

```
void avl::CompareImages_CVG
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 float inChromaAmount,
 float inValueAmount,
 float inGradientAmount,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inChromaAmount	float	0.0 – ∞	0.6f	Proportion of chromatic information in output image
→	inValueAmount	float	0.0 – ∞	0.3f	Proportion of value information in output image
→	inGradientAmount	float	0.0 – ∞	0.1f	Proportion of gradient information in output image
←	outImage	Image&			Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Formats of input images differ in CompareImages_CVG.
DomainError	Images sizes are not equal in CompareImages_CVG.

ImageCorrelation

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the correlation of pattern and image.

Syntax

```
void avl::ImageCorrelation
(
 const avl::Image& inImage,
 const avl::Image& inPatternImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::CorrelationMeasure::Type inCorrelationMeasure,
 float& outCorrelation
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPatternImage	const Image&		Pattern to be compared with input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inCorrelationMeasure	CorrelationMeasure::Type		Measure of correlation
←	outCorrelation	float&		Value of correlation of pattern and image

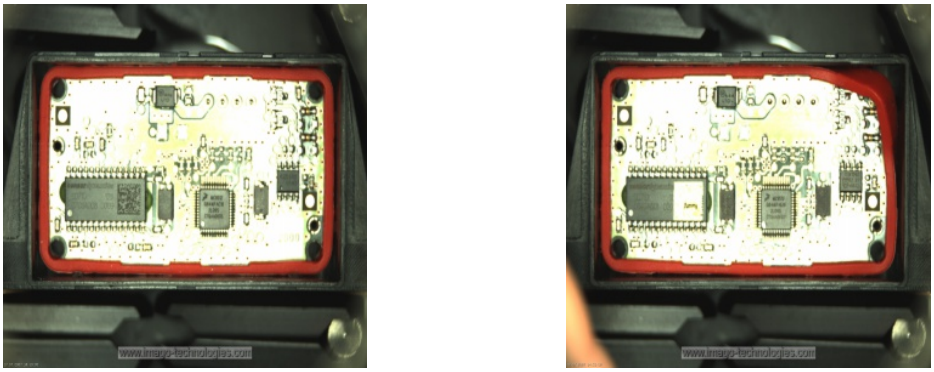
Description

The operation computes the correlation between two images using the selected measure.

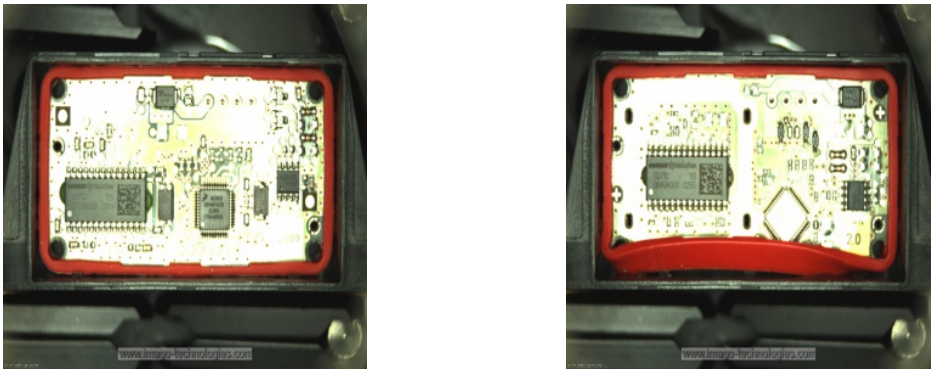
- If the **inCorrelationMeasure** is set to **CrossCorrelation** then the resulting **outCorrelation** is the sum of products of corresponding pixel values of the images.
- If the **inCorrelationMeasure** is set to **NormalizedCrossCorrelation** then the resulting **outCorrelation** is the normalized sum of products of corresponding pixel values of the images. This value always lies in closed interval $[-1,1]$, with 1 indicating the images ideal correlation.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the format of an image one can use filters contained in Image Conversions category.

Examples



Normalized cross correlation between the sample images equals 0.919.



Normalized cross correlation between the sample images equals 0.798.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported correlation measure in ImageCorrelation.

See Also

- ImageCorrelationImage – Computes an image of correlation between a pattern and the input image at each possible location.
- LocateMultipleObjects_NCC – Finds all occurrences of a predefined template on an image by analysing the normalized correlation between pixel values.

ImageCorrelationImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes an image of correlation between a pattern and the input image at each possible location.

Applications: This filter is used internally by the Gray-based Template Matching.

Syntax

```
void avl::ImageCorrelationImage
(
 const avl::Image& inImage,
 const avl::Image& inPatternImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inPatternRoi,
 avl::CorrelationMeasure::Type inCorrelationMeasure,
 avl::Image& outImage
)
```

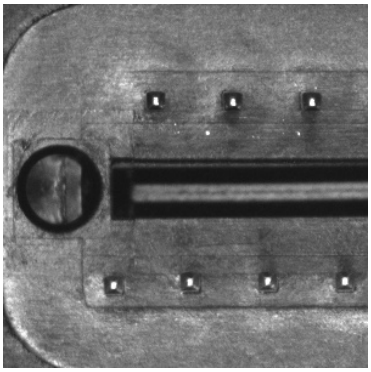
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPatternImage	const Image&		Pattern to be compared with input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inPatternRoi	Optional<const Region&>	NIL	Range of pixels in the pattern to be processed
→	inCorrelationMeasure	CorrelationMeasure::Type		Measure of correlation
←	outImage	Image&		Output image

Description

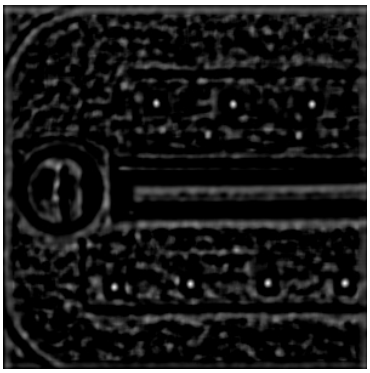
The operation computes the correlation between **inImage** and **inPatternImage**. The **inPatternImage** is aligned at each location of the **inImage** and the similarity between the **inPatternImage** and the corresponding part of the **inImage** is estimated using the **inCorrelationMeasure** as in ImageCorrelation filter. The result is stored in the pixel of the **outImage** that corresponds to the location at which the center of **inPatternImage** was aligned to the **inImage**.

Examples

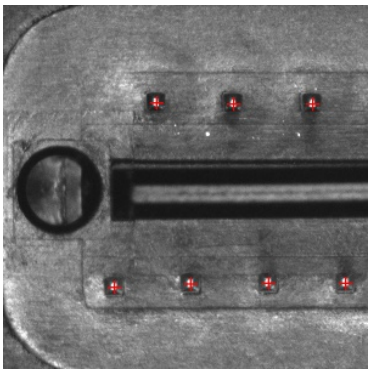


*A sample **inImage**.*

*A sample **inPatternImage**.*



*The resulting **outImage** multiplied by 255.*



*The locations in the **inImage** corresponding to the brightest points of the **outImage**.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation supports processing on OpenCL compatible device (when inRoi=NIL, inPatternRoi=NIL and pixel type is uint8).

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported correlation measure in ImageCorrelationImage.

See Also

- ImageCorrelation – Computes the correlation of pattern and image.
- LocateMultipleObjects_NCC – Finds all occurrences of a predefined template on an image by analysing the normalized correlation between pixel values.

ImageDifference

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Measures dissimilarity between two images.

Syntax

```
void avl::ImageDifference
(
 const avl::Image& inImage,
 const avl::Image& inPatternImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::DistanceMeasure::Type inDistanceMeasure,
 float& outDifference
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPatternImage	const Image&		Pattern to be compared with input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inDistanceMeasure	DistanceMeasure::Type		Measure of distance
←	outDifference	float&		Value of difference between pattern and image

Description

The operation computes the approximate difference between two images using the selected distance measure.

- If the **inDistanceMeasure** is set to **MeanError** then the resulting **outDifference** is the average difference between corresponding pixel values of the images.
- If the **inDistanceMeasure** is set to **MeanSquaredError** then the resulting **outDifference** is the average squared difference between corresponding pixel values of the images.

The operation requires that the images being processed have equal format and dimensions, otherwise an error with appropriate description occurs. To obtain an image of desired dimensions one can use ResizeImage or CropImage filter. To alter the format of an image one can use filters contained in Image Conversions category.

Examples

Mean error between the sample images equals 16.034.

Mean squared error between the sample images equals 2754.164.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8 (for inDistanceMeasure = MeanError).

This operation is optimized for SSE3 technology for pixels of types: UINT16 (for inDistanceMeasure = MeanError), UINT8 (for inDistanceMeasure = MeanSquaredError), REAL.

This operation is optimized for SSE4 technology for pixels of types: INT16, UINT16 (for inDistanceMeasure = MeanSquaredError).

This operation is optimized for AVX2 technology for pixels of types: UINT8, INT16, UINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, UINT16 (for inDistanceMeasure = MeanError), INT16 (for inDistanceMeasure = MeanError), REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported distance measure in ImageDifference.

See Also

- ImageDifferenceImage – Computes an image of differences between a moving pattern and the input image.
- LocateMultipleObjects_SAD – Finds multiple occurrences of a predefined template on an image by analysing the Square Average Difference between pixel values.
- DifferenceImage – Computes the non-negative distances between corresponding pixel values.

ImageDifferenceImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an image of differences between a moving pattern and the input image.

Syntax

```
void avl::ImageDifferenceImage
(
 const avl::Image& inImage,
 const avl::Image& inPatternImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<const avl::Region&> inPatternRoi,
 avl::DistanceMeasure::Type inDistanceMeasure,
 avl::Image& outImage
)
```

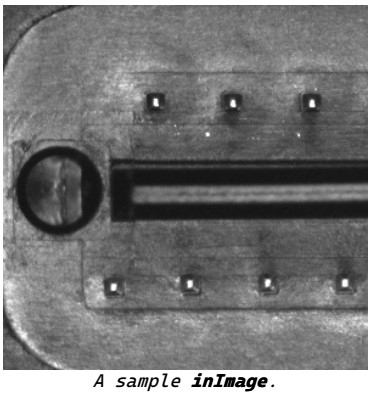
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPatternImage	const Image&		Pattern to be compared with input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inPatternRoi	Optional<const Region&>	NIL	Range of pixels in the pattern to be processed
→	inDistanceMeasure	DistanceMeasure::Type		Measure of distance
←	outImage	Image&		Output image

Description

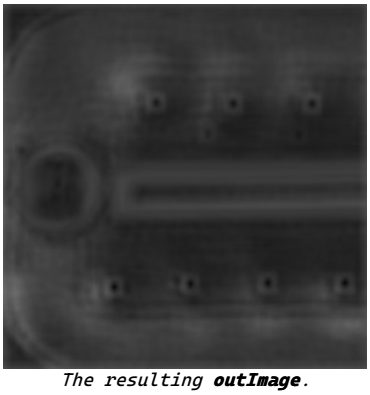
The operation computes the difference between **inImage** and **inPatternImage**. The **inPatternImage** is aligned at each location of the **inImage** and the similarity between the **inPatternImage** and the corresponding part of the **inImage** is estimated using the **inDifferenceMeasure** as in ImageDifference filter. The result is stored in the pixel of the **outImage** that corresponds to the location at which the center of **inPatternImage** was aligned to the **inImage**.

Examples

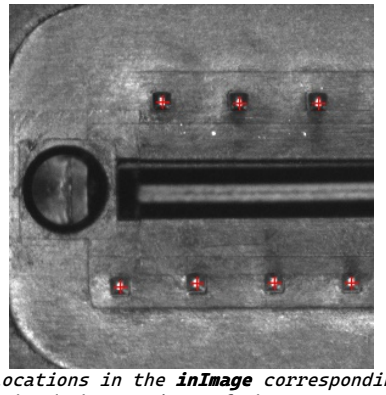


*A sample **inImage**.*

*A sample **inPatternImage**.*



*The resulting **outImage**.*



*The locations in the **inImage** corresponding to the darkest points of the **outImage**.*

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8 (for inDistanceMeasure = MeanError).

This operation is optimized for SSE3 technology for pixels of types: UINT16 (for inDistanceMeasure = MeanError), UINT8 (for inDistanceMeasure = MeanSquaredError), REAL.

This operation is optimized for SSE4 technology for pixels of types: INT16, UINT16 (for inDistanceMeasure = MeanSquaredError).

This operation is optimized for AVX2 technology for pixels of types: UINT8, INT16, UINT16, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, UINT16 (for inDistanceMeasure = MeanError), INT16 (for inDistanceMeasure = MeanError), REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported distance measure in ImageDifferenceImage.

See Also

- ImageDifference – Measures dissimilarity between two images.
- LocateMultipleObjects_SAD – Finds multiple occurrences of a predefined template on an image by analysing the Square Average Difference between pixel values.

71. Path Global Transforms

Table of content:

- ConvertToEquidistantPath
- CreateBicircularCurve
- DilatePolygon
- ErodePolygon
- ExtendPath
- FindLongestSubpath
- ReducePath
- RemovePathSelfIntersections
- SegmentPath
- StretchPath

ConvertToEquidistantPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a new path whose characteristic points lie on the input path, but are equally spaced.

Syntax

```
void avl::ConvertToEquidistantPath
(
 const avl::Path& inPath,
 float inStep,
 avl::EquidistanceType::Type inEquidistanceType,
 avl::Path& outPath
)
```

Parameters

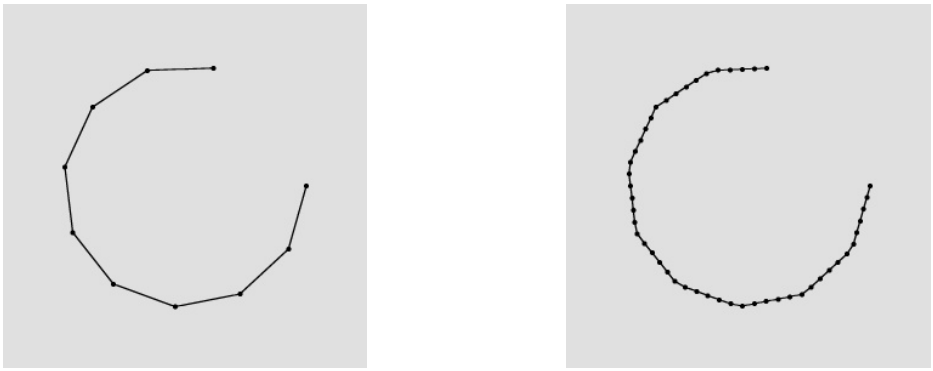
	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inStep	float	0.0 – ∞	1.0f	Requested distance between consecutive points
→	inEquidistanceType	EquidistanceType::Type			Defines how the distance is measured
←	outPath	Path&			Output path

Description

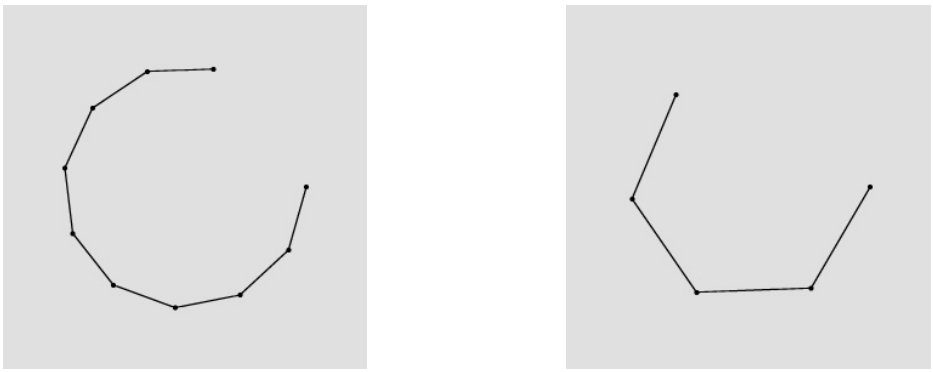
The operation follows a path from its beginning to the end, reselecting its characteristic points every **inStep** pixels. Note that this operation can significantly change the shape of a path, especially when the **inStep** value is relatively big. The output path's last point is mostly not the same as the input path's last point, because it would lead to last output path's segment being too short.

To reduce the number of points in a path preserving its shape, one can use ReducePath filter.

Examples



ConvertToEquidistantPath *run on the sample path with* ***inStep*** *= 10 and* ***inEquidistanceType*** *= OutputPathEquidistance.*



ConvertToEquidistantPath *run on the sample path with* ***inStep*** *= 100 and* ***inEquidistanceType*** *= OutputPathEquidistance.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input step has to be positive in ConvertToEquidistantPath.

See Also

- ReducePath – Reduces the number of points in a path preserving its shape with the specified precision.

CreateBicircularCurve

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates a bicircular curve passing through the points of the leading path.

Applications: This is a fast algorithm that approximates Bezier's splines for dense paths.

Syntax

```
void avl::CreateBicircularCurve
(
 const avl::Path& inLeadingPath,
 int inInterpolationPointCount,
 avl::Path& outBicircularCurve
)
```

Parameters

	Name	Type	Default	Description
→	inLeadingPath	const Path&		The path that will have its corners rounded
→	inInterpolationPointCount	int	8	Number of points used for interpolation between each pair of points on the input path
←	outBicircularCurve	Path&		A smooth output path

DilatePolygon

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Enlarges a polygon by a given radius.

Syntax

```
void avl::DilatePolygon
(
 const avl::Path& inPolygon,
 float inRadius,
 bool inRasterMode,
 avl::Path& outPolygon
)
```

Parameters

	Name	Type	Default	Description
➡	inPolygon	const Path&		Input polygon
➡	inRadius	float	1.0f	
➡	inRasterMode	bool	False	
⬅	outPolygon	Path&		Output polygon

Errors

List of possible exceptions:

Error type	Description
DomainError	Open path on input in DilatePolygon.

ErodePolygon

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shrinks a polygon by a given radius.

Syntax

```
void avl::ErodePolygon
(
 const avl::Path& inPolygon,
 float inRadius,
 bool inRasterMode,
 avl::Path& outPolygon
)
```

Parameters

	Name	Type	Default	Description
➡	inPolygon	const Path&		Input polygon
➡	inRadius	float	1.0f	
➡	inRasterMode	bool	False	
⬅	outPolygon	Path&		Output polygon

ExtendPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Resizes the first or the last segment of a path.

Syntax

```
void avl::ExtendPath
(
 avl::Path& ioPath,
 float inExtraLength1,
 float inExtraLength2
)
```

Parameters

	Name	Type	Default	Description
↔	ioPath	Path&		
→	inExtraLength1	float		
→	inExtraLength2	float		

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot extend a closed path in ExtendPath.

FindLongestSubpath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a new path from the longest sequence of segments of the input path that turn gently.

Applications: Can be used for removing noise.

Syntax

```
void avl::FindLongestSubpath
(
 const avl::Path& inPath,
 float inMaxTurnAngle,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path, possibly noised
→	inMaxTurnAngle	float	0.0 – 180.0	30.0f	Maximum angle between two consecutive segments in the output path
←	outPath	Path&			Output path

ReducePath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Reduces the number of points in a path preserving its shape with the specified precision.

Syntax

```
void avl::ReducePath
(
 const avl::Path& inPath,
 float inMaxDistance,
 avl::Path& outPath,
 atl::Array<avl::Path>& diagIntermediatePaths
)
```

Parameters

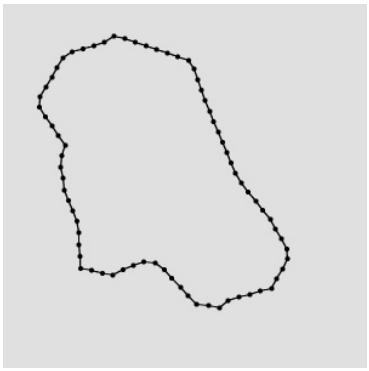
	Name	Type	Range	Default	Description
➡	inPath	const Path&			Input path
➡	inMaxDistance	float	0.0 – ∞	0.5f	Maximum distance between (possibly removed in the process) characteristic point of the input path and the output path.
⬅	outPath	Path&			Reduced path
🔍	diagIntermediatePaths	Array<Path>&			Intermediate results on all levels of recursion of the Ramer algorithm

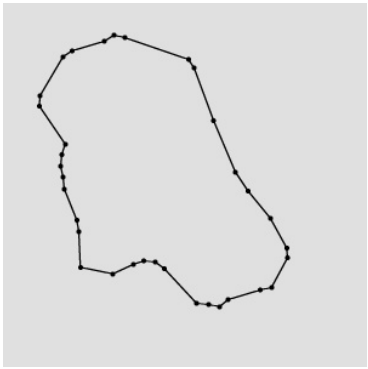
Description

The operation removes some of the characteristic points of the input path preserving its shape with the selected precision. The algorithm guarantees that each of the removed characteristic points lies within the **inMaxDistance** distance from the resulting path.

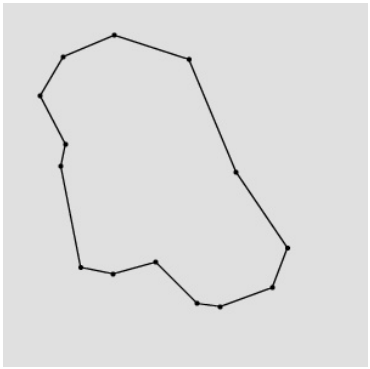
The operation works with open and closed paths as well.

Examples





ReducePath *run on the sample path array with* ***inMaxDistance*** *= 0.5.*



ReducePath *run on the sample path array with* ***inMaxDistance*** *= 5.*

See Also

- ConvertToEquidistantPath – Creates a new path whose characteristic points lie on the input path, but are equally spaced.

RemovePathSelfIntersections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Removes all self-intersections from a given path.

Syntax

```
void avl::RemovePathSelfIntersections
(
 const avl::Path& inPath,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outPath	Path&		Path with no self-intersections

SegmentPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Splits a path into parts that can be approximated as segments or arcs.

Applications: Usually used to recognize a particular structure of an object contour or to guide a CNC machine.

Syntax

```
void avl::SegmentPath
(
 const avl::Path& inPath,
 float inSmoothingStdDev,
 float inMaxDeviation,
 avl::PathSegmentationMode::Type inSegmentationMode,
 atl::Optional<float> inMaxArcRadius,
 atl::Array<avl::Path>& outStraight,
 atl::Array<avl::Path>& outArciform,
 atl::Array<avl::Segment2D>& outSegments,
 atl::Array<avl::Arc2D>& outArcs
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Path to be segmented
→	inSmoothingStdDev	float	0.0 – ∞		Standard deviation used for initial gaussian smoothing of the segmented path
→	inMaxDeviation	float	0.0 – ∞	0.5f	Maximal distance between any point of a classified segment to the abstract shape
→	inSegmentationMode	PathSegmentationMode::Type			Whether to use arcs for segmentation
→	inMaxArcRadius	Optional<float>	0.0 – ∞	10.0f	Maximal radius of an arc fitted to segment
←	outStraight	Array<Path>&			Parts classified as straight segments
←	outArciform	Array<Path>&			Parts classified as arciform segments
←	outSegments	Array<Segment2D>&			Segments corresponding to sections of path from outStraight
←	outArcs	Array<Arc2D>&			Arcs corresponding to sections of path from outArciform

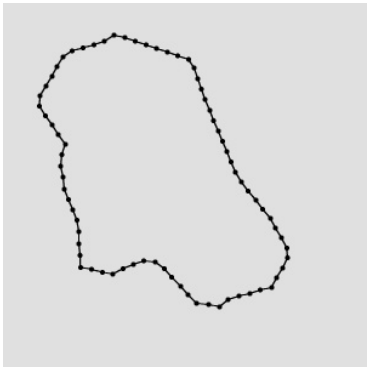
Description

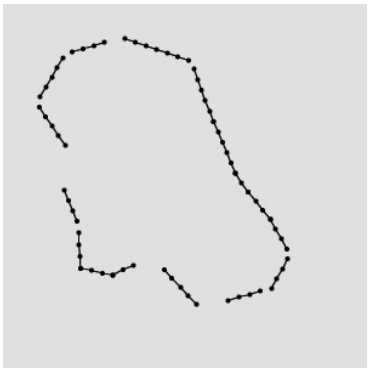
The operation segments the **inPath** into parts of preferably simple shape. Each of the resulting parts is classified as one of the following:

- **Straight section** – in which case it is returned in **outStraight** output array
- **Arciform section** – in which case it is returned in **outArciform** output array

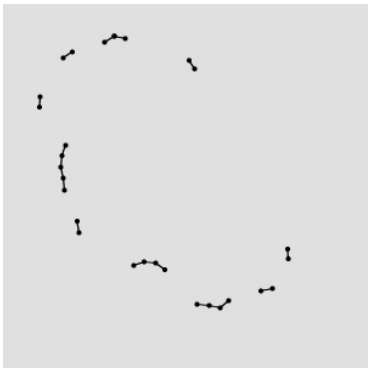
The operation guarantees that the maximal distance from any of the resulting path section to the corresponding abstract shape (line segment or circular arc) is less than **inMaxDeviation**.

Examples





*The resulting **outStraight** array (some of the paths in the picture have common ends but in fact each straight part is a separate path).*



*The resulting **outArciform** array.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in SegmentPath.

See Also

- JoinAdjacentPaths – Joins those paths of an array which endpoints lie near enough.

StretchPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Moves, rotates and scales the path so that its end-points end up at the given two points.

Syntax

```
void avl::StretchPath
(
 const avl::Path& inPath,
 const avl::Point2D& inNewEndpoint1,
 const avl::Point2D& inNewEndpoint2,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path, must be open
→	inNewEndpoint1	const Point2D&		New starting point of the path
→	inNewEndpoint2	const Point2D&		New ending point of the path
←	outPath	Path&		Output path

Errors

List of possible exceptions:

Error type	Description
DomainError	Path cannot be closed in StretchPath.
DomainError	Path too short in Stretch Path.

72. Profile Local Transforms

Table of content:

- ConvolveProfile
- DifferentiateProfile
- DifferentiateProfile_Step
- DilateProfile
- ErodeProfile
- SharpenProfile
- SmoothProfile_Gauss
- SmoothProfile_Gauss_Mask
- SmoothProfile_Mean

ConvolveProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Applies a user-defined convolution to a profile.

Syntax

```
void avl::ConvolveProfile
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const atl::Array<float>& inMask,
 bool inNormalizeMaskValues,
 atl::Optional<int> inMaskOrigin,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Profile to be processed
→	inRange	Optional<const Range&>	NIL	
→	inMask	const Array<float>&		Convolution kernel mask that will be applied to the profile
→	inNormalizeMaskValues	bool	False	If set to true, the kernel mask will be normalized so that its values sum up to one
→	inMaskOrigin	Optional<int>	NIL	Index of the kernel mask element that will be aligned against the profile values
←	outProfile	Profile&		Output profile

Description

The operation computes each value as a convolution of **inProfile** and **inMask** values. Values which mask exceeds profile dimension are set to zero.

Errors

List of possible exceptions:

Error type	Description
DomainError	Convolution mask is empty in ConvolveProfile.
DomainError	Mask origin exceeds dimensions of convolution mask in ConvolveProfile.
DomainError	Normalization of kernel mask which values add up to zero was requested in ConvolveProfile.
DomainError	Range exceeds the input profile in ConvolveProfile.

DifferentiateProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the derivative of a profile.

Syntax

```
void avl::DifferentiateProfile
(
 const avl::Profile& inProfile,
 const bool inCyclic,
 avl::DifferentiationMethod::Type inDifferentiationMethod,
 avl::Profile& outDerivative
)
```

Parameters

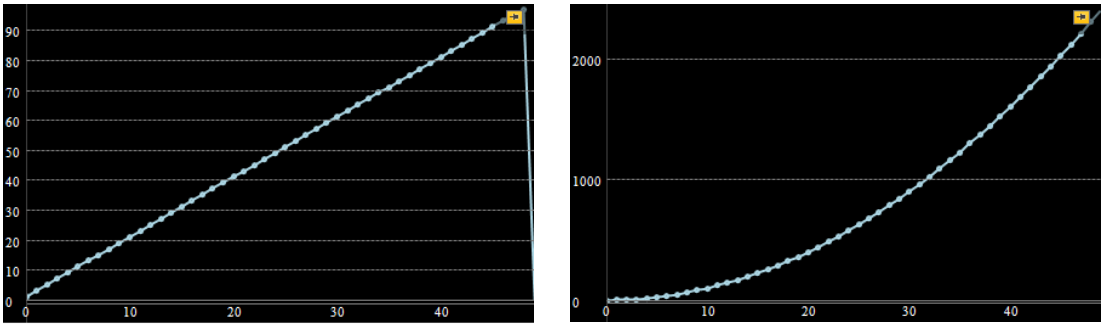
	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inCyclic	const bool		Defines whether to compute differences between first and last elements
→	inDifferentiationMethod	DifferentiationMethod::Type	Central	
←	outDerivative	Profile&		

Description

Computes finite difference of profile using forward, backward or central difference method. If **inCyclic** is False then depending of chosen difference method values for first or last element of **inProfile** is undefined and thus outermost values are doubled when necessary.

For instance, in forward difference method, last element of derivative profile is always zero. In backward difference method, first element is always zero.

Examples



*On the left **DifferentiateProfile** with **inCyclic** = False, **inDifferentiationMethod** = Forward performed on profile being shown on the right.*

PROFILE DifferentiateProfile_Step

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the derivative of a profile with a given difference step.

Syntax

```
void avl::DifferentiateProfile_Step
(
 const avl::Profile& inProfile,
 const bool inCyclic,
 int inStep,
 avl::Profile& outDerivative
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inCyclic	const bool			Defines whether to compute differences between first and last elements
→	inStep	int	1 – ∞	2	
←	outDerivative	Profile&			

PROFILE DilateProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Changes a profile by choosing maximum point within a kernel.

Syntax

```
void avl::DilateProfile
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const int inKernelRadius,
 const bool inCyclic,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Profile to be processed
→	inRange	Optional<const Range&>		NIL	
→	inKernelRadius	const int	0 – ∞	3	Defines the width of the kernel as '2 * inKernelRadius + 1'
→	inCyclic	const bool			Defines whether the first element should be considered adjacent to the last element
←	outProfile	Profile&			Output profile

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in DilateProfile.

ErodeProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Changes a profile by choosing minimum point within a kernel.

Syntax

```
void avl::ErodeProfile
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const int inKernelRadius,
 const bool inCyclic,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Profile to be processed
→	inRange	Optional<const Range&>		NIL	
→	inKernelRadius	const int	0 – ∞	3	Defines the width of the kernel as '2 * inKernelRadius + 1'
→	inCyclic	const bool			Defines whether the first element should be considered adjacent to the last element
←	outProfile	Profile&			Output profile

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ErodeProfile.

SharpenProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Sharpens a profile using a 3x1 filter.

Syntax

```
void avl::SharpenProfile
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const float inFactor,
 const bool inCyclic,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inFactor	const float	0.0 – ∞	1.0f	
→	inCyclic	const bool			Defines whether the first element should be considered adjacent to the last element
←	outProfile	Profile&			Output profile

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inProfile** and **outProfile**

Read more about In-place Computation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in SharpenProfile.

SmoothProfile_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths a profile by averaging points within a kernel using gaussian-weighted average.

Applications: Noise removal.

Syntax

```
void avl::SmoothProfile_Gauss
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const float inStdDev,
 const float inKernelRelativeSize,
 const bool inCyclic,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inStdDev	const float	0.0 – ∞	0.6f	Standard deviation of the gaussian kernel
→	inKernelRelativeSize	const float	0.0 – ∞	3.0f	A multiple of the standard deviation determining the size of the kernel
→	inCyclic	const bool			Defines whether the first element should be considered adjacent to the last element
←	outProfile	Profile&			Output profile

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in SmoothProfile_Gauss.

SmoothProfile_Gauss_Mask

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths a profile by averaging points with one of ten pre-computed Gauss kernels.

Applications: Noise removal. Faster, but less accurate.

Syntax

```
void avl::SmoothProfile_Gauss_Mask
(
 const avl::Profile& inProfile,
 float inStdDev,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inStdDev	float	0.0 – 3.0	0.6f	
←	outProfile	Profile&			Output profile

Hardware Acceleration

This operation is optimized for SSE2 technology.

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

SmoothProfile_Mean

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths a profile by averaging points within a kernel.

Syntax

```
void avl::SmoothProfile_Mean
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const int inKernelRadius,
 const bool inCyclic,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inKernelRadius	const int	0 – ∞	3	Defines the width of the kernel as '2 * inKernelRadius + 1'
→	inCyclic	const bool			Defines whether the first element should be considered adjacent to the last element
←	outProfile	Profile&			Output profile

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in SmoothProfile_Mean.

73. Image Spatial Transforms

Table of content:

- UncropImage

CreateAffineTransformMatrix

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates affine transform matrix matrix. Return product of matrices: Translation * Rotation * Scale * Shearing.

Syntax

```
void avl::CreateAffineTransformMatrix
(
 const float inScaleX,
 const float inScaleY,
 const avl::Vector2D& inTranslation,
 const float inRotation,
 const float inShearingX,
 const float inShearingY,
 avl::Matrix& outTransformMatrix
)
```

Parameters

	Name	Type	Range	Default	Description
→	inScaleX	const float	-∞ – ∞	1.0f	Image scale in X axis
→	inScaleY	const float	-∞ – ∞	1.0f	Image scale in Y axis
→	inTranslation	const Vector2D&			Image translation
→	inRotation	const float		0.0f	Image rotation in degree
→	inShearingX	const float	-∞ – ∞		Shearing in X axis coefficient
→	inShearingY	const float	-∞ – ∞		Shearing in Y axis coefficient
←	outTransformMatrix	Matrix&			Return product of matrices: Translation * Rotation * Scale * Shearing

CreateImagePyramid

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates an array of images, each downsampled from the previous one.

Applications: Frequently used to create scale-invariant image analysis algorithms.

Syntax

```
void avl::CreateImagePyramid
(
 const avl::Image& inImage,
 int inMinPyramidLevel,
 int inMaxPyramidLevel,
 avl::DownsampleFunction::Type inFunction,
 atl::Array<avl::Image>& outImagePyramid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inMinPyramidLevel	int	0 – 12		
→	inMaxPyramidLevel	int	0 – 12		
→	inFunction	DownsampleFunction::Type		Mean	
←	outImagePyramid	Array<Image>&			

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 1xUINT8.

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

CreateImagePyramid_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates an array of images, each downsampled from the previous, gauss-smoothed one.

Applications: Frequently used to create scale-invariant image analysis algorithms. Reduces impact of pixel aliasing.

Syntax

```
void avl::CreateImagePyramid_Gauss
(
 const avl::Image& inImage,
 avl::GaussKernel::Type inGaussKernelSize,
 int inMinPyramidLevel,
 int inMaxPyramidLevel,
 avl::DownsampleFunction::Type inFunction,
 atl::Array<avl::Image>& outImagePyramid
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inGaussKernelSize	GaussKernel::Type			
→	inMinPyramidLevel	int	0 – 12		
→	inMaxPyramidLevel	int	0 – 12		
→	inFunction	DownsampleFunction::Type		Mean	
←	outImagePyramid	Array<Image>&			

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 1xUINT8.

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

CropImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image from a box-shaped fragment of the input image (with margins if requested).

Applications: Reduction of the amount of image data to be stored in memory.

Syntax

```
void avl::CropImage
(
 const avl::Image& inImage,
 const avl::Box& inSelection,
 const avl::Pixel& inBorderColor,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inSelection	const Box&		Box defining a subimage to be cropped
→	inBorderColor	const Pixel&		Color used for locations outside the selection
←	outImage	Image&		Output image

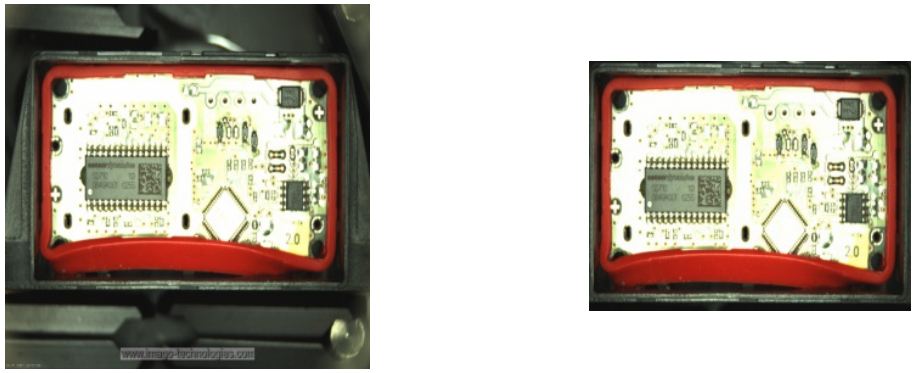
Description

The operation extracts part of the **inImage** that corresponds to the **inSelection** box.

Hints

- It is usually recommended to use Local Coordinate Systems rather than image cropping.

Examples



***CropImage** performed on the sample image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- UncropImage – Inverse of CropImage.

CropImageToQuadrangle

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates an image from a quadrangle on another image.

Applications: Can be used for cropping an image from a slightly distorted rectangle. Do not use it for perspective distortion though.

Syntax

```
void avl::CropImageToQuadrangle
(
 const avl::Image& inImage,
 const avl::Path& inQuadrangle,
 atl::Optional<const avl::CoordinateSystem2D&> inQuadrangleAlignment,
 atl::Optional<const avl::Size&> inOutputSize,
 avl::InterpolationMethod::Type inInterpolationMethod,
 int inMargin,
 const avl::Pixel& inBorderColor,
 avl::Image& outImage,
 atl::Optional<avl::Path&> outAlignedQuadrangle = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inQuadrangle	const Path&			Rectangle defining a rotated subimage
→	inQuadrangleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the rectangle to the position of the inspected object
→	inOutputSize	Optional<const Size&>		NIL	Dimensions of the output image
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
→	inMargin	int	0 – 65535		Width of an additional margin for the output image
→	inBorderColor	const Pixel&			Color used for locations outside the quadrangle
←	outImage	Image&			Output image
←	outAlignedQuadrangle	Optional<Path&>		NIL	Input quadrangle after transformation (in the image coordinates)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedQuadrangle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Quadrangle should be specified by a closed path with exactly 4 points in CropImageToQuadrangle.

CropImageToRectangle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an image from a rectangular fragment of another image (with black margins if requested).

Applications: Usually used for creating images of individual objects, e.g. after Template Matching.

Syntax

```
void avl::CropImageToRectangle
(
 const avl::Image& inImage,
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 avl::CropScaleMode::Type inScaleMode,
 avl::InterpolationMethod::Type inInterpolationMethod,
 float inMargin,
 const avl::Pixel& inBorderColor,
 avl::Image& outImage,
 atl::Optional<avl::Rectangle2D&> outAlignedRectangle = atl::NIL,
 atl::Optional<avl::CoordinateSystem2D&> outOutputAlignment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRectangle	const Rectangle2D&			Rectangle defining a rotated subimage
→	inRectangleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the rectangle to the position of the inspected object
→	inScaleMode	CropScaleMode::Type		InputScale	InputScale keeps the input scale unchanged, AlignedScale rescales according to the input alignment scale
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
→	inMargin	float	0.0 – ∞		Width of an additional margin for the output image
→	inBorderColor	const Pixel&			Color used for locations outside the rectangle
←	outImage	Image&			Output image
←	outAlignedRectangle	Optional<Rectangle2D&>		NIL	Input rectangle after transformation (in the image coordinates)
←	outOutputAlignment	Optional<CoordinateSystem2D&>		NIL	Alignment of the output image

Optional Outputs

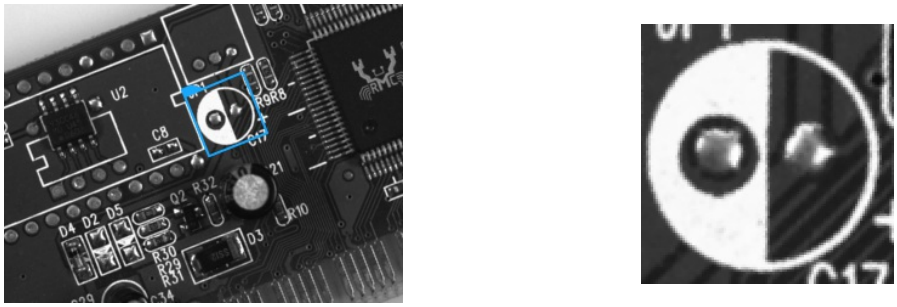
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRectangle**, **outOutputAlignment**.

Read more about Optional Outputs.

Hints

- It is usually recommended to use Local Coordinate Systems rather than image cropping.
- To obtain output images with constant dimensions regardless of **inRectangleAlignment** set **inScaleMode** to **AlignedScale**. The output image size will be equal to **inRectangle** size optionally modified by **inMargin**.

Examples



***CropImageToRectangle** used to extract an image of an object.*

DownsampleImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shrinks an image by the factor of two along each axis.

Applications: Usually used to speed-up image analysis at the cost of reduced precision. It is internally used to implement the pyramid strategy in template matching filters.

Syntax

```
void avl::DownsampleImage
(
 const avl::Image& inImage,
 const int inScaleStep,
 avl::DownsampleFunction::Type inFunction,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScaleStep	const int	0 – 12	1	Defines how many times the image size is divided by 2
→	inFunction	DownsampleFunction::Type		Mean	
←	outImage	Image&			Output image

Description

The operation shrinks the **inImage** reducing its dimensions by a factor of two **inScaleStep** times.

Remarks

The operation produces a new image by averaging four neighboring pixels from the source image repeatedly. New width and height of image are always rounded up, thus pixels from source image at last row or column are averaged in pairs or copied when corresponding dimension is odd.

This operation can be used as faster replacement for ShrinkImageNTimes.

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- ShrinkImageNTimes – Shrinks an image by a natural factor along each axis.
- ResizeImage_Relative – Resizes an image by a factor along each axis.

DownsampleImage_Midlevels

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Shrinks an image by the factor of 1.5 or SQRT(2) along each axis.

Applications: Usually used to speed-up image analysis at the cost of reduced precision. It is internally used to implement the pyramid strategy.

Syntax

```
void avl::DownsampleImage_Midlevels
(
 const avl::Image& inImage,
 const int inScaleStep,
 avl::MidlevelScale::Type inMidlevelScale,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScaleStep	const int	0 – 24	1	Defines how many times the image size is divided by 1.5 or SQRT(2)
→	inMidlevelScale	MidlevelScale::Type			Determines which scale will be used
←	outImage	Image&			Output image

Hardware Acceleration

This operation is optimized for SSE2 technology for pixels of type: 1xUINT8.

This operation is optimized for SSSE3 technology for pixels of type: 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

ImageAlongArc

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates an image from pixels traversed along an arc.

Applications: E.g. "Unwrapping" of object contours, so that they appear as 1D structures on the output image.

Syntax

```
void avl::ImageAlongArc
(
 const avl::Image& inImage,
 const avl::Arc2D& inAxisArc,
 atl::Optional<const avl::CoordinateSystem2D&> inAxisArcAlignment,
 int inScanWidth,
 avl::Axis::Type inAxisType,
 avl::InterpolationMethod::Type inInterpolationMethod,
 atl::Optional<const avl::Pixel&> inBorderColor,
 avl::Image& outImage,
 atl::Optional<avl::Arc2D&> outAlignedAxisArc = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints = atl::Dummy<atl::Array<avl::Path> >()
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inAxisArc	const Arc2D&			Input arc
➡	inAxisArcAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the axis arc to the position of the inspected object
➡	inScanWidth	int	1 – ∞	5	The width of the stripe of pixels along the given arc
➡	inAxisType	Axis::Type		Y	Type of axis the transformed axis arc will be parallel to
➡	inInterpolationMethod	InterpolationMethod::Type		Bilinear	The interpolation method used to compute pixel brightness in locations of not-integer coordinates
➡	inBorderColor	Optional<const Pixel&>		NIL	Color of pixel outside image. If inBorderColor = NIL then algorithm repeats color of boarder.
⬅	outImage	Image&			Output image
⬅	outAlignedAxisArc	Optional<Arc2D&>		NIL	Input arc after transformation (in the image coordinates)
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points corresponding to one row of the resulting image

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedAxisArc**.

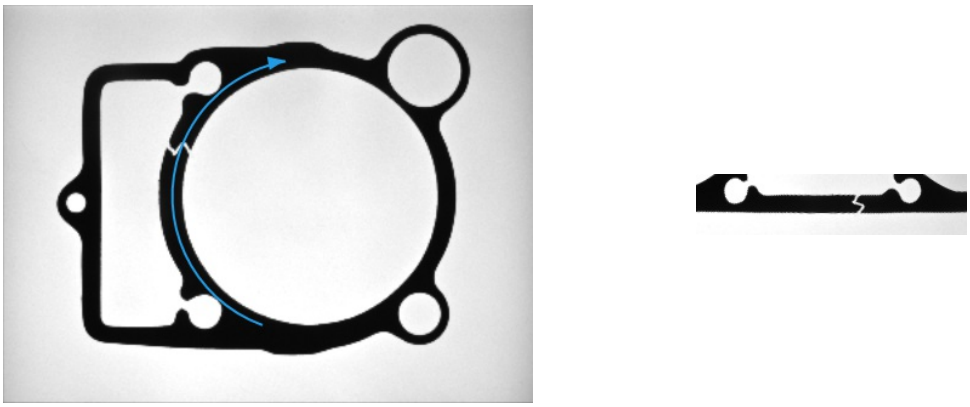
Read more about Optional Outputs.

Description

The operation transforms the stripe of pixels of width **inScanWidth** along the **inAxisArc** in the way that transforms the arc into straight segment. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive.

The optional parameter **inAxisArcAlignment** defines the transform to be performed on the **inAxisArc** so that the resulting path is defined in a new context, e.g. returned by one of Template Matching filters.

Examples



ImageAlongArc *performed on the sample image with* ***inScanWidth*** *= 50 and* ***inAxisType*** *= X.*

See Also

- ImageProfileAlongPath – Creates a series of segments across the input path, measures the average pixel intensity on each of the segments, and creates the final profile from those values.
- ImageAlongPath – Creates an image from pixels traversed along a path.

ImageAlongPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates an image from pixels traversed along a path.

Applications: E.g. "Unwrapping" of object contours, so that they appear as 1D structures on the output image.

Syntax

```
void avl::ImageAlongPath
(
 const avl::Image& inImage,
 const avl::Path& inAxisPath,
 atl::Optional<const avl::CoordinateSystem2D&> inAxisPathAlignment,
 int inScanWidth,
 avl::Axis::Type inAxisType,
 avl::InterpolationMethod::Type inInterpolationMethod,
 atl::Optional<const avl::Pixel&> inBorderColor,
 avl::Image& outImage,
 atl::Optional<avl::Path&> outAlignedAxisPath = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints = atl::Dummy<atl::Array<avl::Path>>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inAxisPath	const Path&			Input path
→	inAxisPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the axis path to the position of the inspected object
→	inScanWidth	int	1 – ∞	5	The width of the stripe of pixels along the given path
→	inAxisType	Axis::Type		Y	Type of axis the transformed axis path will be parallel to
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	The interpolation method used to compute pixel brightness in locations of not-integer coordinates
→	inBorderColor	Optional<const Pixel&>		Pixel (X: 0.0f Y: 0.0f Z: 0.0f W: 0.0f)	Color of pixel outside image. If inBorderColor = NIL then algorithm repeats color of boarder.
←	outImage	Image&			Output image
←	outAlignedAxisPath	Optional<Path&>		NIL	Input path after transformation (in the image coordinates)
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points corresponding to one row of the resulting image

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedAxisPath**.

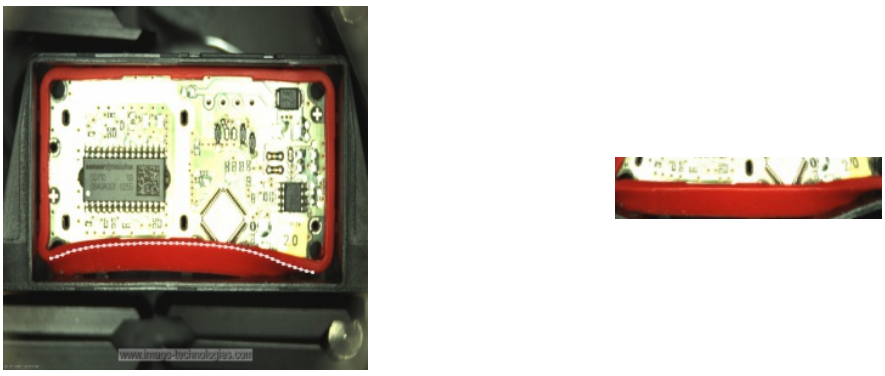
Read more about Optional Outputs.

Description

The operation transforms the stripe of pixels of width **inScanWidth** along the **inAxisPath** in the way that transforms the path into straight segment. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive.

The optional parameter **inAxisPathAlignment** defines the transform to be performed on the **inAxisPath** so that the resulting path is defined in a new context, e.g. returned by one of Template Matching filters.

Examples



__ImageAlongPath__ performed on the sample image with __inScanWidth__ = 50 and __inAxisType__ = Y. The result was transposed using TransposeImage for clarity.

See Also

- ImageProfileAlongPath – Creates a series of segments across the input path, measures the average pixel intensity on each of the segments, and creates the final profile from those values.
- ImageAlongArc – Creates an image from pixels traversed along an arc.

ImageInversePolarTransform

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Transforms an image from polar or log-polar space to euclidean space.

Syntax

```
void avl::ImageInversePolarTransform
(
 const avl::Image& inImage,
 const avl::Point2D& inCenter,
 avl::PolarSpaceType::Type inInputSpaceType,
 avl::PolarInterpolationMethod::Type inInterpolation,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inCenter	const Point2D&		Center of the coordinate system in output image
→	inInputSpaceType	PolarSpaceType::Type		Method of transformation
→	inInterpolation	PolarInterpolationMethod::Type		Method of underlying interpolation
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 3×uint8, 1×int16, 3×int16, 1×uint16, 3×uint16, 1×real, 3×real.

Read more about pixel formats in Image documentation.

Description

Reverses ImagePolarTransform using the following transformation:

$$src(x,y) = dst(\rho,\phi)$$

where

$$\rho = m\sqrt{x^2+y^2}, \phi = \arctan(\frac{y}{x}),$$

for linear-polar space, and

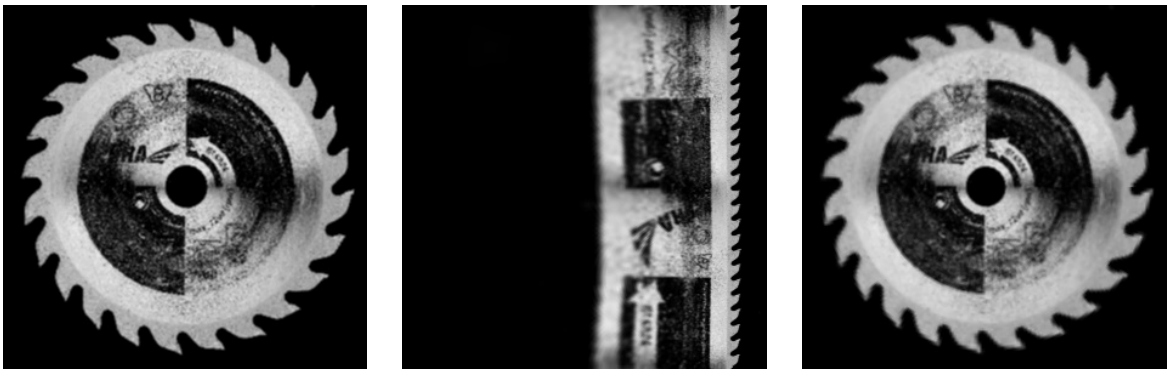
$$\rho = k\log\sqrt{x^2+y^2}, \phi = \arctan(\frac{y}{x}),$$

for log-polar space, which emulates the human "foveal vision".

Parameters m and k are chosen so that entire source image could fit into output image.

Transformation does not change image dimensions.

Examples



*Original image, ImagePolarTransform and **ImageInversePolarTransform** performed on the sample image with **inCenter** = (150,150) for log-polar space type.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in ImageInversePolarTransform. Supported formats: 1xUInt8, 3xUInt8, 1xInt16, 3xInt16, 1xUInt16, 3xUInt16, 1xReal, 3xReal.

See Also

- ImagePolarTransform – Transforms an image to polar or log-polar space.

ImagePolarTransform

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Transforms an image to polar or log-polar space.

Syntax

```
void avl::ImagePolarTransform
(
 const avl::Image& inImage,
 const avl::Point2D& inCenter,
 avl::PolarSpaceType::Type inOutputSpaceType,
 avl::PolarInterpolationMethod::Type inInterpolation,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inCenter	const Point2D&		Center of the coordinate system in input image
→	inOutputSpaceType	PolarSpaceType::Type		Method of transformation
→	inInterpolation	PolarInterpolationMethod::Type		Method of underlying interpolation
←	outImage	Image&		Output image

Description

It uses the following transformation:

$$dst(\rho, \phi) = src(x, y),$$

where

$$\rho = m\sqrt{x^2 + y^2}, \phi = \arctan(\frac{y}{x}),$$

for linear-polar space, and

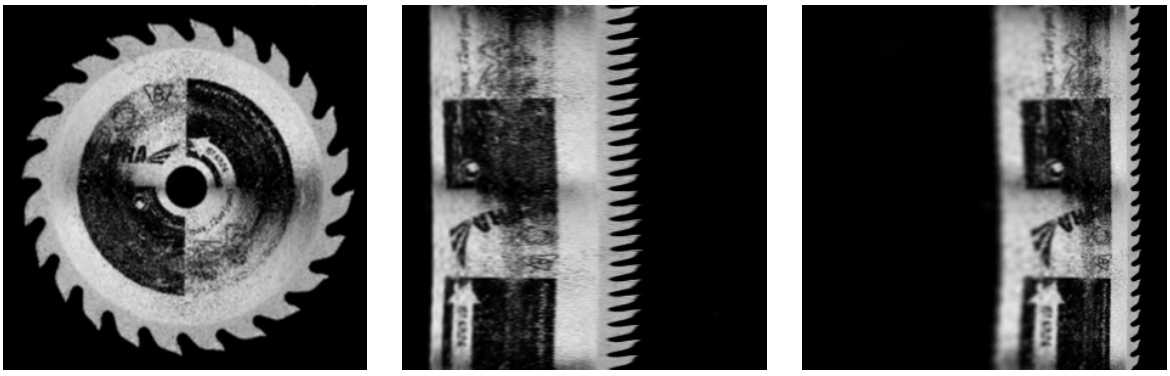
$$\rho = k\log\sqrt{x^2 + y^2}, \phi = \arctan(\frac{y}{x}),$$

for log-polar space, which emulates the human "foveal vision".

Parameters m and k are chosen so that entire source image could fit into output image.

Transformation does not change image dimensions.

Examples



__ImagePolarTransform__ performed on the sample image with __inCenter__ = (150,150), and __inOutputSpaceType__ Polar and LogPolar respectively.

See Also

- ImageInversePolarTransform – Transforms an image from polar or log-polar space to euclidean space.

JoinImages

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a single image by glueing together the two input images in horizontal or vertical direction.

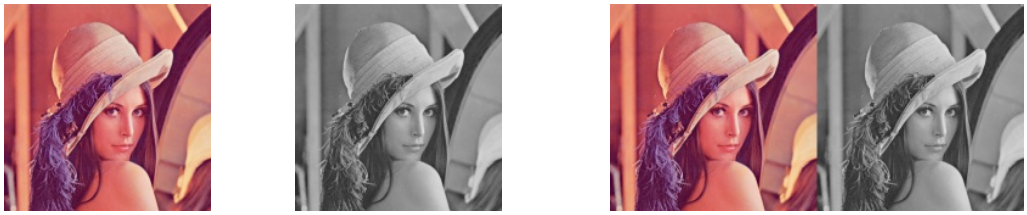
Syntax

```
void avl::JoinImages
(
 const avl::Image& inImage1,
 const avl::Image& inImage2,
 atl::Optional<const avl::Image&> inImage3,
 atl::Optional<const avl::Image&> inImage4,
 avl::JoinDirection::Type inDirection,
 const int inMargin,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage1	const Image&			First input image
→	inImage2	const Image&			Second input image
→	inImage3	Optional<const Image&>		NIL	Third input image
→	inImage4	Optional<const Image&>		NIL	Fourth input image
→	inDirection	JoinDirection::Type			Direction in which images are joined
→	inMargin	const int	0 – ∞	0	Thickness (in pixels) of black frame around joined images
←	outImage	Image&			Output image

Examples



JoinImages *used to join two images side by side into a single image.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input images do not have compatible dimensions in JoinImages.
DomainError	Input images do not have the same pixel format in JoinImages.
DomainError	Unknown value of JoinDirection in JoinImages.

JoinImages_OfArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a single image by glueing together many input images in horizontal or vertical direction.

Syntax

```
void avl::JoinImages_OfArray
(
 const atl::Array<avl::Image>& inImages,
 avl::JoinDirection::Type inDirection,
 const int inMargin,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImages	const Array<Image>&			Array of input images
→	inDirection	JoinDirection::Type			Direction in which images are joined
→	inMargin	const int	0 – ∞	0	Thickness (in pixels) of black frame around joined images
←	outImage	Image&			Output image

Examples

JoinImages *used to join multiple image stripes into a single image.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input images do not have compatible dimensions in JoinImages_OfArray.
DomainError	Input images do not have the same pixel format in JoinImages_OfArray.
DomainError	Unknown value of JoinDirection in JoinImages_OfArray.

JoinImages_OfSeries

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a single image by glueing together a series of input images in horizontal or vertical direction.

Applications: Joining images from a line-scan camera, which produces too few lines at a time.

Syntax

```
void avl::JoinImages_OfSeries
(
 JoinImages_OfSeriesState& ioState,
 const avl::Image& inImage,
 avl::JoinDirection::Type inDirection,
 const int inSeriesSize,
 const int inMargin,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	JoinImages_OfSeriesState&			Object used to maintain state of the function.
→	inImage	const Image&			Input image
→	inDirection	JoinDirection::Type			Direction in which images are joined
→	inSeriesSize	const int	1 – ∞		Number of images which are joined
→	inMargin	const int	0 – ∞	0	Thickness (in pixels) of black frame around joined images
←	outImage	Conditional<Image>&			Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Input images do not have compatible dimensions in JoinImages_OfSeries.
DomainError	Input images do not have the same pixel format in JoinImages_OfSeries.

MirrorImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Reverses the order of the input image columns or rows depending on inMirrorDirection value.

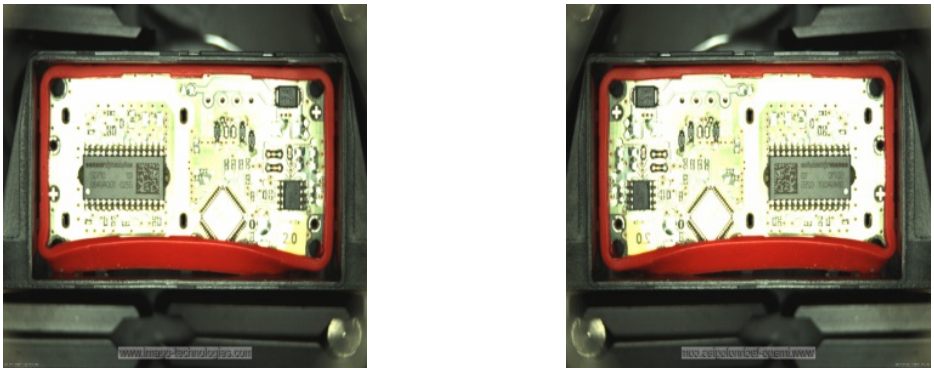
Syntax

```
void avl::MirrorImage
(
 const avl::Image& inImage,
 avl::MirrorDirection::Type inMirrorDirection,
 avl::Image& outImage
)
```

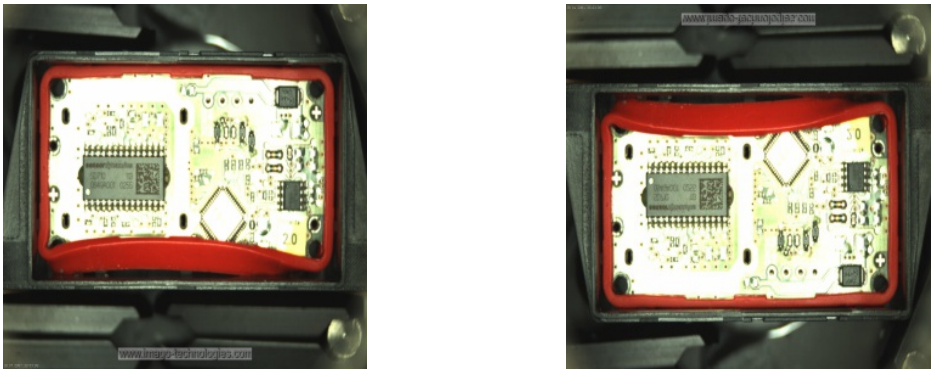
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inMirrorDirection	MirrorDirection::Type	Vertical	Reverse the order of image columns (horizontal direction) or rows (vertical direction).
←	outImage	Image&		Output image

Examples



***MirrorImage** with **inMirrorDirection** = Horizontal.*



***MirrorImage** with **inMirrorDirection** = Vertical.*

Hardware Acceleration

This operation is optimized for SSSE3 technology for pixels of types: 1xUINT8, 1xINT8, 1xUINT16, 1xINT16, 1xINT32, 1xREAL, 2xUINT8, 2xINT8, 2xUINT16, 2xINT16, 3xUINT8, 3xINT8, 4xUINT8, 4xINT8.

This operation is optimized for NEON technology for pixels of type: 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- TransposeImage – Flips and rotates an image so that columns are exchanged with rows.

Also in **AVL Lite**

ResizeImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Enlarges or shrinks an image to new dimensions.

Syntax

```
void avl::ResizeImage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<int> inNewWidth,
 atl::Optional<int> inNewHeight,
 avl::ResizeMethod::Type inResizeMethod,
 avl::Image& outImage
)
```

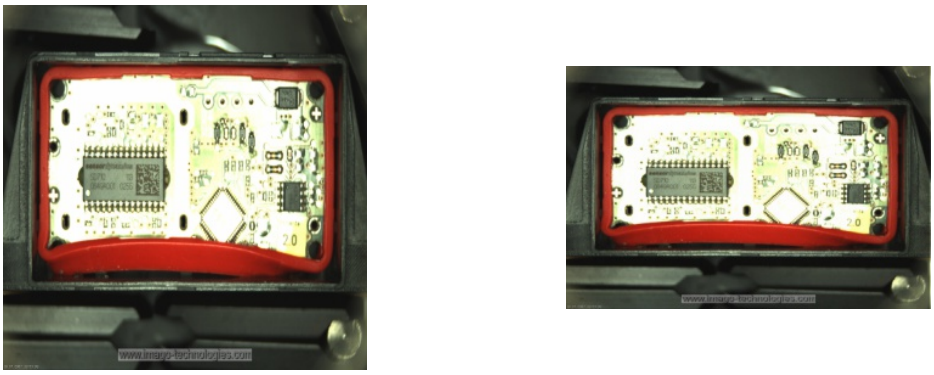
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Box&>		NIL	Box defining a subimage to be cropped and resized.
→	inNewWidth	Optional<int>	1 - 65535	NIL	
→	inNewHeight	Optional<int>	1 - 65535	NIL	
→	inResizeMethod	ResizeMethod::Type			
←	outImage	Image&			Output image

Description

The operation stretches or shrinks the **inImage** so that the dimensions of the **outImage** equal **inNewWidth**, **inNewHeight**. Three modes of pixel interpolation are available, with Area mode giving best results, but being most computationally expensive.

Examples



ResizeImage *performed on the sample image with* ***inNewWidth*** *= 300,* ***inNewHeight*** *= 200.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE2 technology for pixels of types: UINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

This operation is optimized for SSE41 technology for pixels of types: UINT8(when inResizeMethod = Bilinear), 3xUINT8(when inResizeMethod = Bilinear).

This operation is optimized for AVX2 technology for pixels of types: UINT8 (when inResizeMethod = Area or inResizeMethod = Bilinear), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area or inResizeMethod = Bilinear), 3xUINT16 (when inResizeMethod = Area).

This operation is optimized for NEON technology for pixels of types: UINT8 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty image on input in ResizeImage.
DomainError	Input and output images are not distinct in ResizeImage.
DomainError	ROI is out of inImage range in ResizeImage.

See Also

- ResizeImage_Relative – Resizes an image by a factor along each axis.

ResizeImage_FixedAspectRatio

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes one dimension of the image to a desired length while the other dimension is set to a length such that the aspect ration of the image is maintained.

Syntax

```
void avl::ResizeImage_FixedAspectRatio
(
 const avl::Image& inImage,
 atl::Optional<int> inNewLength,
 avl::Dimension::Type inDimension,
 avl::ResizeMethod::Type inResizeMethod,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inNewLength	Optional<int>	1 – 65535	NIL	The length in pixels that the chosen dimension will be set to
→	inDimension	Dimension::Type			The dimension that will be set to the given length
→	inResizeMethod	ResizeMethod::Type			
←	outImage	Image&			Output image

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE2 technology for pixels of types: UINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

This operation is optimized for AVX2 technology for pixels of types: UINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty image on input in ResizeImage_FixedAspectRatio.
DomainError	Unsupported dimension given in inDimension, only Width and Height are supported in ResizeImage_FixedAspectRatio.

Also in AVL Lite

ResizeImage_Relative

Header: AVL.h
Namespace: avl
Module: FoundationLite

Resizes an image by a factor along each axis.

Syntax

```
void avl::ResizeImage_Relative
(
 const avl::Image& inImage,
 float inHorizontalScale,
 float inVerticalScale,
 avl::ResizeMethod::Type inResizeMethod,
 avl::Image& outImage
)
```

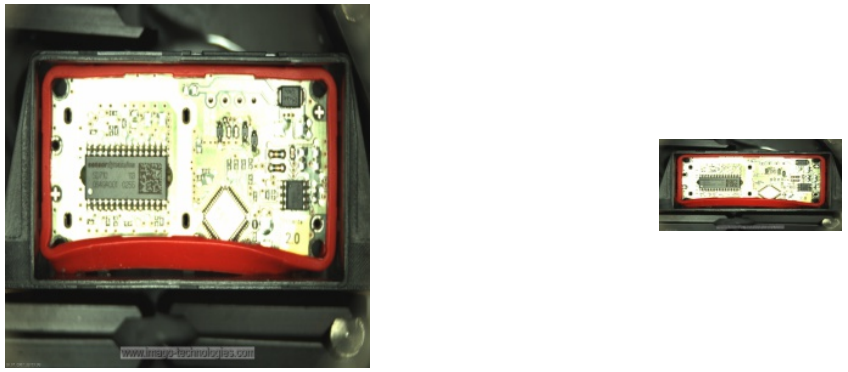
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inHorizontalScale	float	0.0 – 65535.0	1.0f	
→	inVerticalScale	float	0.0 – 65535.0	1.0f	
→	inResizeMethod	ResizeMethod::Type			
←	outImage	Image&			Output image

Description

The operation stretches or shrinks the **inImage** so that its dimensions are scaled, accordingly, by the factor of **inHorizontalScale**, **inVerticalScale**. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive.

Examples



ResizeImage_Relative *performed on the sample image with* ***inHorizontalScale*** *= 0.5,* ***inVerticalScale*** *= 0.25.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE2 technology for pixels of types: UINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

This operation is optimized for AVX2 technology for pixels of types: UINT8 (when inResizeMethod = Area), UINT16 (when inResizeMethod = Area), 3xUINT8 (when inResizeMethod = Area), 3xUINT16 (when inResizeMethod = Area).

See Also

- ResizeImage – Enlarges or shrinks an image to new dimensions.

Also in AVL Lite

RotateImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Rotates an image clockwise.

Syntax

```
void avl::RotateImage
(
 const avl::Image& inImage,
 float inAngle,
 avl::RotationSizeMode::Type inSizeMode,
 avl::InterpolationMethod::Type inInterpolationMethod,
 const bool inInverse,
 avl::Image& outImage,
 atl::Optional<avl::CoordinateSystem2D&> outOutputAlignment = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inAngle	float	45.0f	Rotation angle (clockwise)
→	inSizeMode	RotationSizeMode::Type		
→	inInterpolationMethod	InterpolationMethod::Type	Bilinear	
→	inInverse	const bool	False	'True' changes rotation to counter-clockwise
←	outImage	Image&		Output image
←	outOutputAlignment	Optional<CoordinateSystem2D&>	NIL	Alignment of the output image

Optional Outputs

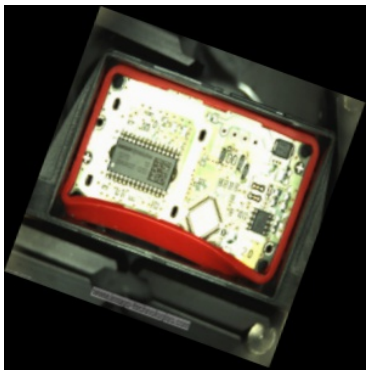
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outOutputAlignment**.

Read more about Optional Outputs.

Description

The operation rotates the **inImage** around its center. Dimensions of the resulting image depends on **inSizeMode** parameter. In 'Fit' mode size is extended to fit the rotated image. In 'Preserve' mode size of source image is left unchanged and part of rotated image may be lost. Two modes of pixel interpolation are available, the bilinear filtering being more precise and computationally expensive.

Examples



RotateImage *performed on the sample image in Fit mode with* ***inAngle*** *= 20.0.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image dimensions too big in RotateImage.

ShearImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a leant image (shifts the rows).

Applications: Image preprocessing when there are slanted objects.

Syntax

```
void avl::ShearImage
(
 const avl::Image& inImage,
 float inShear,
 avl::Axis::Type inAxis,
 avl::InterpolationMethod::Type inInterpolationMethod,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inShear	float	$-\infty$ $-\infty$	0.0f	Relative shift between consecutive rows or columns of the image
→	inAxis	Axis::Type			Switches between horizontal or vertical shearing
→	inInterpolationMethod	InterpolationMethod::Type		Bilinear	
←	outImage	Image&			Output image

Description

The filter **ShearImage** applies basic affine transform to each image's pixel.

Shear affine transform is defined as:

When **X axis** is selected

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & inShear \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

When **Y axis** is selected

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ inShear & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Examples

ShearImage *performed on the sample image with* ***inAxis*** *= X,* ***inShear*** *= 0.50.*

Errors

List of possible exceptions:

Error type	Description
DomainError	inImage and outImage are not distinct in ShearImage.

See Also

- ShearRegion – Computes a leant region.

ShrinkImageNTimes

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Shrinks an image by a natural factor along each axis.

Syntax

```
void avl::ShrinkImageNTimes
(
 const avl::Image& inImage,
 atl::Optional<const avl::Box&> inRoi,
 int inNX,
 const atl::Optional<int>& inNY,
 avl::Image& outImage
)
```

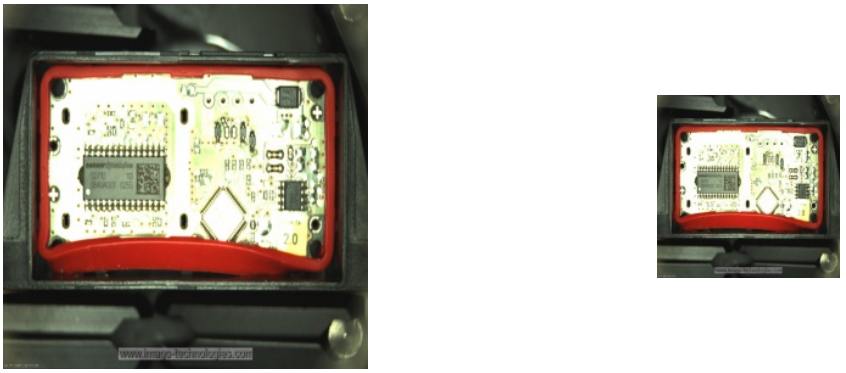
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Box&>		NIL	Range of pixels to be processed
→	inNX	int	1 – ∞	2	
→	inNY	const Optional<int>&	1 – ∞	NIL	
←	outImage	Image&			Output image

Description

The operation shrinks the **inImage** reducing its dimensions by a natural factor.

Examples



ShrinkImageNTimes *performed on the sample image with* ***inNX*** *= 2,* ***inNY*** *= 2.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for SSE2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for AVX2 technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

This operation is optimized for NEON technology for pixels of types: UINT8, SINT8, UINT16, SINT16, SINT32, REAL.

Errors

List of possible exceptions:

Error type	Description
DomainError	ROI is out of inImage range in ShrinkImageNTimes.

See Also

- DownsampleImage – Shrinks an image by the factor of two along each axis.
- ResizeImage – Enlarges or shrinks an image to new dimensions.
- ResizeImage_Relative – Resizes an image by a factor along each axis.
- ShrinkRegionNTimes – Shrinks a region by a natural factor along each axis.
- ShrinkProfileNTimes – Reduces the length of a profile N-times by averaging each N consecutive elements.

TransformImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Transforms an image by the provided transformation matrix.

Syntax

```
void avl::TransformImage
(
 const avl::Image& inImage,
 const avl::Matrix& inTransformMatrix,
 const bool inInverse,
 const avl::InterpolationMethod::Type& inInterpolation,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inTransformMatrix	const Matrix&		Transform matrix
→	inInverse	const bool		
→	inInterpolation	const InterpolationMethod::Type&		Image quality
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Input transformation matrix must have dimensions 3x3 in TransformImage.
DomainError	Unable to transform image with provided parameters TransformImage.

TranslateImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Translates an image by a vector, without changing its dimensions.

Applications: E.g. camera shaking reduction.

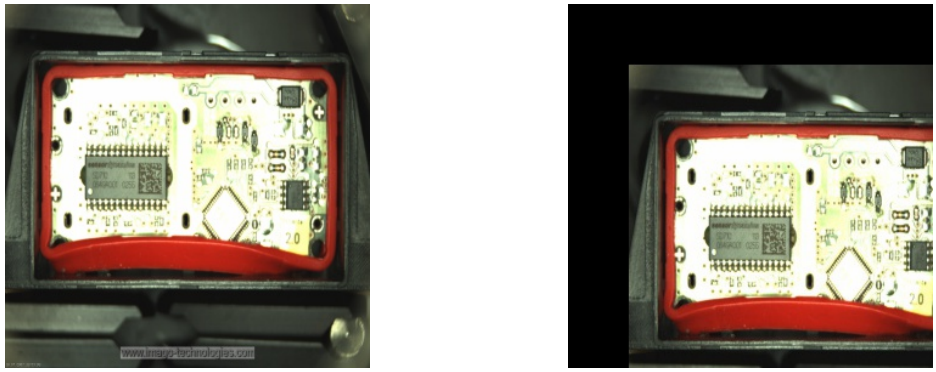
Syntax

```
void avl::TranslateImage
(
 const avl::Image& inImage,
 const avl::Pixel& inBorder,
 int inDeltaX,
 int inDeltaY,
 bool inInverse,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inBorder	const Pixel&		Color used to fill pixels outside of the translated image
→	inDeltaX	int		Horizontal shift
→	inDeltaY	int		Vertical shift
→	inInverse	bool		Switches to the inverse operation
←	outImage	Image&		Output image

Examples



TranslateImage *performed on the sample image.*

TranslatePixels

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Moves the pixels of the input image by the vectors specified with inVectorImage.

Syntax

```
void avl::TranslatePixels
(
 const avl::Image& inImage,
 const avl::Image& inVectorImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::InterpolationMethod::Type inImageInterpolation,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inVectorImage	const Image&		Two-channel image specifying translation vector for each pixel
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inImageInterpolation	InterpolationMethod::Type		
←	outImage	Image&		Output image

Requirements

For input **inVectorImage** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image size are not equal in TranslatePixels.
DomainError	Incorrect vector image format in TranslatePixels.
DomainError	Region exceeds an input image in TranslatePixels.
DomainError	Unknown interpolation method in TranslatePixels.
DomainError	Not supported inVectorImage pixel format in TranslatePixels. Supported formats: 2xReal.

TransposeImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Flips and rotates an image so that columns are exchanged with rows.

Applications: Useful when operations on image columns should be replaced with operations on image rows, which are much faster due to the cache memory.

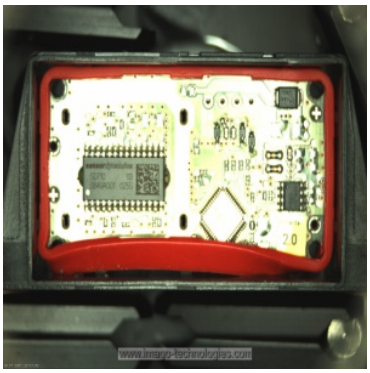
Syntax

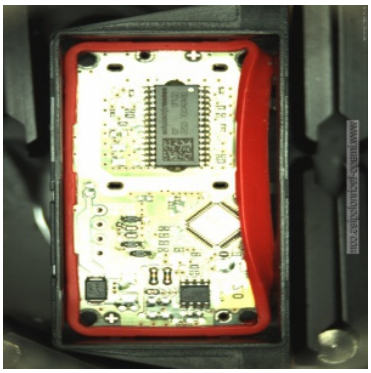
```
void avl::TransposeImage
(
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImage	Image&		Output image

Examples





TransposeImage *performed on the sample image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- MirrorImage – Reverses the order of the input image columns or rows depending on inMirrorDirection value.

Also in AVL Lite

TrimImageToRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Trims an image to the area of the specified region.

Syntax

```
void avl::TrimImageToRegion
(
 const avl::Image& inImage,
 const avl::Region& inRegion,
 const avl::Pixel& inBorderColor,
 avl::Image& outImage
)
```

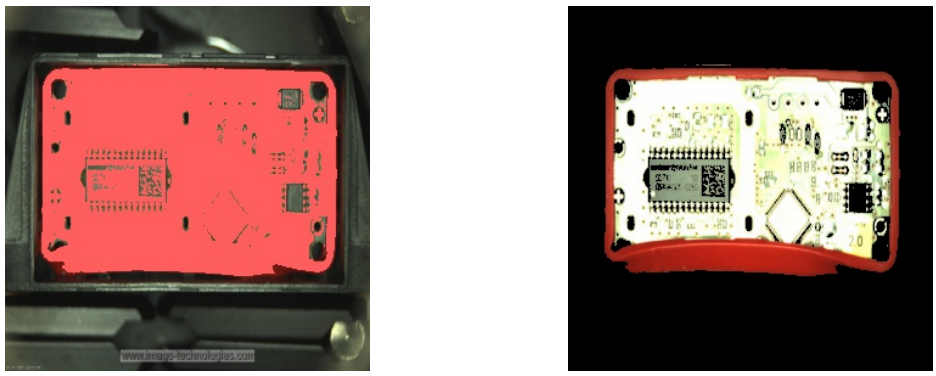
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRegion	const Region&		Input region
→	inBorderColor	const Pixel&		Color used for locations outside the region
←	outImage	Image&		Output image

Description

The operation extracts part of the **inImage** that corresponds to the region. Other pixels are set to **inBorderColor** color.

Examples



TrimImageToRegion *performed on the sample image and region.*

Also in AVL Lite

UncropImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Inverse of CropImage.

Syntax

```
void avl::UncropImage
(
 const avl::Image& inImage,
 const avl::Box& inSelection,
 int inWidth,
 int inHeight,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inSelection	const Box&			The same value as in CropImage
→	inWidth	int	0 – ∞		Width of the original image
→	inHeight	int	0 – ∞		Height of the original image
←	outImage	Image&			Output image

Description

Inverse of CropImage. Can create borders around original image e.g. passing x:50 y:50 will create new image with filled 50 pixels on top and 50 on left of the original image. inWidth and inHeight specifies the new image dimensions, Width and Height from inSelection property are not used.

Examples

inSelection property	Preview
origin in x:0 y:0	origin in x:50 y:50	

See Also

- CropImage – Creates an image from a box-shaped fragment of the input image (with margins if requested).

CreateArcFittingMap

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Precomputes a data object that is required for fast arc fitting on images.

Applications: Used together with arc fitting, but can be moved before the loop.

Syntax

```
void avl::CreateArcFittingMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::ArcFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 const int inScanCount,
 const int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 avl::ArcFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Dimensions, depth and pixel type of the images on which fitting will be performed
→	inFittingField	const ArcFittingField&			Defines a ring section in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	const int	3 – ∞	10	The number of points that will be searched to estimate the position of the arc
→	inScanWidth	const int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&		.interpolation Bilinear	Parameters controlling the sampling process
←	outFittingMap	ArcFittingMap&			Optimized data required for arc fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

Description

The operation creates a series of scan maps that can be later used by other Shape Fitting filters. Each scan map corresponds to a single scan segment of **inScanWidth** length.

The optional parameter **inFittingFieldAlignment** defines the transform to be performed on the **inFittingField** so that the result is defined in a new context, e.g. returned by one of Template Matching filters.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the Shape Fitting toolset. To read more about this technique, one can refer to the Shape Fitting chapter of our Machine Vision Guide

CreateCircleFittingMap

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Precomputes a data object that is required for fast circle fitting on images.

Applications: Used together with circle fitting, but can be moved before the loop.

Syntax

```
void avl::CreateCircleFittingMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::CircleFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 const int inScanCount,
 const int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 avl::CircleFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Dimensions, depth and pixel type of the images on which fitting will be performed
→	inFittingField	const CircleFittingField&			Defines a ring in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	const int	3 – ∞	10	The number of points that will be searched to estimate the position of the circle
→	inScanWidth	const int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&		.interpolation Bilinear	Parameters controlling the sampling process
←	outFittingMap	CircleFittingMap&			Optimized data required for circle fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

Description

The operation creates a series of scan maps that can be later used by other Shape Fitting filters. Each scan map corresponds to a single scan segment of **inScanWidth** length.

The optional parameter **inFittingFieldAlignment** defines the transform to be performed on the **inFittingField** so that the result is defined in a new context, e.g. returned by one of Template Matching filters.

CreatePathFittingMap

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Precomputes a data object that is required for fast path fitting on images.

Applications: Used together with path fitting, but can be moved before the loop.

Syntax

```
void avl::CreatePathFittingMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::PathFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 atl::Optional<float> inScanStep,
 const int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 avl::PathFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Dimensions, depth and pixel type of the images on which fitting will be performed
→	inFittingField	const PathFittingField&			Defines a stripe in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanStep	Optional<float>	0.0 – ∞	NIL	Optional implicit conversion of the input path to an equidistant one
→	inScanWidth	const int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&		.interpolation Bilinear	Parameters controlling the sampling process
←	outFittingMap	PathFittingMap&			Optimized data required for path fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

Description

The operation creates a series of scan maps that can be later used by other Shape Fitting filters. Each scan map corresponds to a single scan segment of **inScanWidth** length.

The optional parameter **inFittingFieldAlignment** defines the transform to be performed on the **inFittingField** so that the result is defined in a new context, e.g. returned by one of Template Matching filters.

CreateSegmentFittingMap

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Precomputes a data object that is required for fast segment fitting on images.

Applications: Used together with segment fitting, but can be moved before the loop.

Syntax

```
void avl::CreateSegmentFittingMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::SegmentFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 const int inScanCount,
 const int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 SegmentFittingMap& outFittingMap,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Dimensions, depth and pixel type of the images on which fitting will be performed
→	inFittingField	const SegmentFittingField&			Defines a rectangle in which scan segments will be created
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	const int	3 – ∞	10	The number of points that will be searched to estimate the position of the segment
→	inScanWidth	const int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&		.interpolation Bilinear	Parameters controlling the sampling process
←	outFittingMap	SegmentFittingMap&			Optimized data required for segment fitting
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans will be run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Scan fields created for point detection

Description

The operation creates a series of scan maps that can be later used by other Shape Fitting filters. Each scan map corresponds to a single scan segment of **inScanWidth** length.

The optional parameter **inFittingFieldAlignment** defines the transform to be performed on the **inFittingField** so that the result is defined in a new context, e.g. returned by one of Template Matching filters.

DetectArc_LSD

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds arcs in an image using Line Segment Detection method.

Syntax

```
void avl::DetectArc_LSD
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GaussKernel::Type inSmoothing,
 float inEdgeThreshold,
 int inMinLength,
 atl::Array<avl::Arc2D>& outArcs
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the arcs to
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inSmoothing	GaussKernel::Type		_5x5	Predefined Gauss kernel
→	inEdgeThreshold	float	0.1 – ∞	4.0f	Minimum accepted edge magnitude
→	inMinLength	int	0 – ∞	10	Minimum length of output arcs
←	outArcs	Array<Arc2D>&			Found arcs

DetectCircle_LSD

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds circles in the input image using Line Segment Detection method.

Syntax

```
void avl::DetectCircle_LSD
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GaussKernel::Type inSmoothing,
 float inEdgeThreshold,
 float inToleranceCircle,
 int inMinRadius,
 atl::Array<avl::Circle2D>& outCircles
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the circles to
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inSmoothing	GaussKernel::Type		_5x5	Predefined Gauss kernel
→	inEdgeThreshold	float	0.1 – ∞	4.0f	Minimum accepted edge magnitude
→	inToleranceCircle	float	0.001 – ∞	0.6f	Maximum accepted defects in output circles
→	inMinRadius	int	0 – ∞	10	Minimum radius of output circles
←	outCircles	Array<Circle2D>&			Found circles

DetectPolygons_LSD

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds a specified polygons in an image using Line Segment Detection method.

Syntax

```
void avl::DetectPolygons_LSD
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Path& inPath,
 avl::GaussKernel::Type inSmoothing,
 float inEdgeThreshold,
 float inTolerance,
 atl::Array<avl::Path>& outPaths
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the polygons to
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inPath	const Path&			Input Polygon
→	inSmoothing	GaussKernel::Type		_5x5	Predefined Gauss kernel
→	inEdgeThreshold	float	0.1 – ∞	4.0f	Minimum accepted edge magnitude
→	inTolerance	float	0.001 – ∞	1.0f	Maximum accepted defects in output polygons
←	outPaths	Array<Path>&			Found polygons

DetectSegments_LSD

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds segments in an image using Line Segment Detection method.

Syntax

```
void avl::DetectSegments_LSD
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GaussKernel::Type inSmoothing,
 float inEdgeThreshold,
 int inMinLength,
 atl::Array<avl::Segment2D>& outSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the segments to
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inSmoothing	GaussKernel::Type		_5x5	Predefined Gauss kernel
→	inEdgeThreshold	float	0.1 – ∞	4.0f	Minimum accepted edge magnitude
→	inMinLength	int	0 – ∞	10	Minimum length of output segments
←	outSegments	Array<Segment2D>&			Found segments

FitArcToEdges

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Performs a series of 1D edge detections and finds an arc that best matches the detected points.

Applications: Precise detection of an arciform edge, whose rough location is known beforehand.

Syntax

```
void avl::FitArcToEdges
(
 const avl::Image& inImage,
 const avl::ArcFittingMap& inFittingMap,
 const EdgeScanParams& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 float inMaxIncompleteness,
 avl::CircleFittingMethod::Type inFittingMethod,
 atl::Optional<avl::MEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Arc2D>& outArc,
 atl::Optional<atl::Array<atl::Conditional<avl::Edge1D>>&> outEdges = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outBrightnessProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image to fit arc to
→	inFittingMap	const ArcFittingMap&			Input fitting map
→	inEdgeScanParams	const EdgeScanParams&			Parameters controlling the edge extraction process
→	inEdgeSelection	Selection::Type		Selection::Best	Selection mode of edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of edge points not found
→	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit an arc
→	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
←	outArc	Conditional<Arc2D>&			Fitted arc or nothing if the fitting fails
←	outEdges	Optional<Array<Conditional<Edge1D>>&>		NIL	Found edges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual arc points and the corresponding reference arc points
←	outInliers	Optional<Array<Point2D>&>		NIL	Points matching the fitting arc
←	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outInliers**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

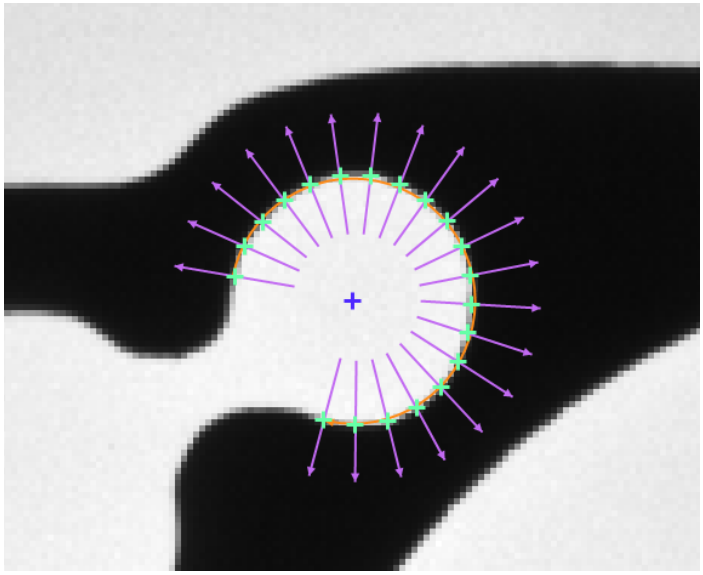
Description

The operation tries to fit a given arc to edges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleEdge filter using **inFittingMap** previously generated from the object being fitted. The found points are then used to determine the actual position of the arc in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outArc** is set to Nil.

Hints

- Connect an input image to the **inImage** input.
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no or too few edge points are found, try decreasing **inEdgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- If some of the scans may produce false results, try different values of the **inOutlierSuppression** input.
- Use the **outEdges** outputs to visualize the scanning results.

Examples



*Fitting an arc to the edges of a semi-hole (**inEdgeScanParams.Transition** = BrightToDark).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the Shape Fitting toolset. To read more about this technique, one can refer to the Shape Fitting chapter of our Machine Vision Guide

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

FitArcToEdges_Direct

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Performs a series of 1D edge detections and finds an arc that best matches the detected points.

Applications: Precise detection of an arciform edge, whose rough location is known beforehand.

Syntax

```
void avl::FitArcToEdges_Direct
(
 const avl::Image& inImage,
 const avl::ArcFittingField& inFittingField,
 atl::Optional<const avl::CoordinateSystem2D&> inFittingFieldAlignment,
 int inScanCount,
 int inScanWidth,

←	outEdges	Optional<Array<Conditional<Edge1D>>&>		NIL	Found edges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual arc points and the corresponding reference arc points
←	outAlignedFittingField	Optional<ArcFittingField&>		NIL	Fitting field used; in the image coordinate system
←	outInliers	Optional<Array<Point2D>&>		NIL	Points matching the fitting arc
←	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outAlignedFittingField**, **outInliers**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

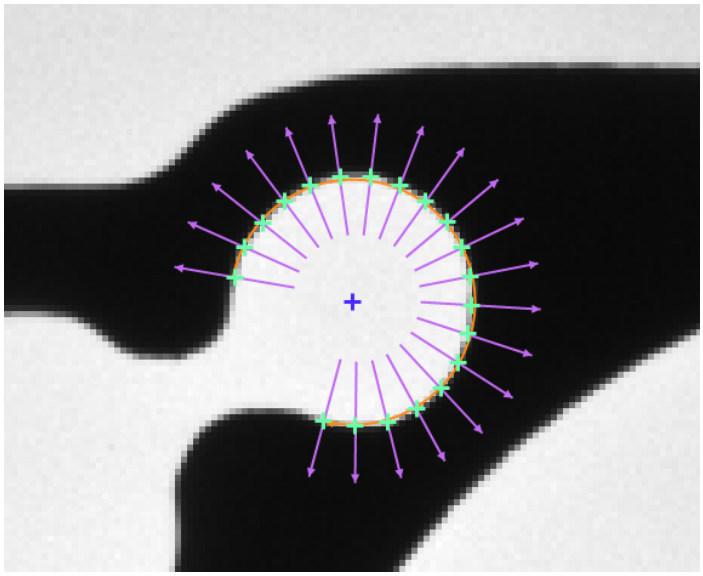
Description

The operation tries to fit a given arc to edges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleEdge_Direct filter along **inScanCount** specific scan segments which length is always equal to the **inFittingField** width and cannot be less than 4. The found points are then used to determine the actual position of the arc in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outArc** is set to Nil.

Hints

- Connect an input image to the **inImage** input.
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no or too few edge points are found, try decreasing **inEdgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- If some of the scans may produce false results, try different values of the **inOutlierSuppression** input.
- Use the **outEdges** outputs to visualize the scanning results.

Examples



*Fitting an arc to the edges of a semi-hole (**inEdgeScanParams.Transition** = BrightToDark).*

Remarks

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the circle to
→	inFittingField	const CircleFittingField&			Circle fitting field
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	int	3 – ∞	10	The number of points that will be searched to estimate the position of the circle
→	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&			Parameters controlling the sampling process
→	inEdgeScanParams	const EdgeScanParams&		EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 1.0f MinMagnitude: 5.0f EdgeTransition: BrightToDark)	Parameters controlling the edge extraction process
→	inEdgeSelection	Selection::Type			Selection mode of edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of edge points not found
→	inFittingMethod	CircleFittingMethod::Type		AlgebraicTaubin	Method used to fit a circle
→	inOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
←	outCircle	Conditional<Circle2D>&			Fitted circle or nothing if the fitting fails
←	outEdges	Optional<Array<Conditional<Edge1D>>&>		NIL	Found edges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual circle points and the corresponding reference circle points
←	outAlignedFittingField	Optional<CircleFittingField&>		NIL	Fitting field used; in the image coordinate system
←	outInliers	Optional<Array<Point2D>&>		NIL	Points matching the fitting Circle
←	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outAlignedFittingField**, **outInliers**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

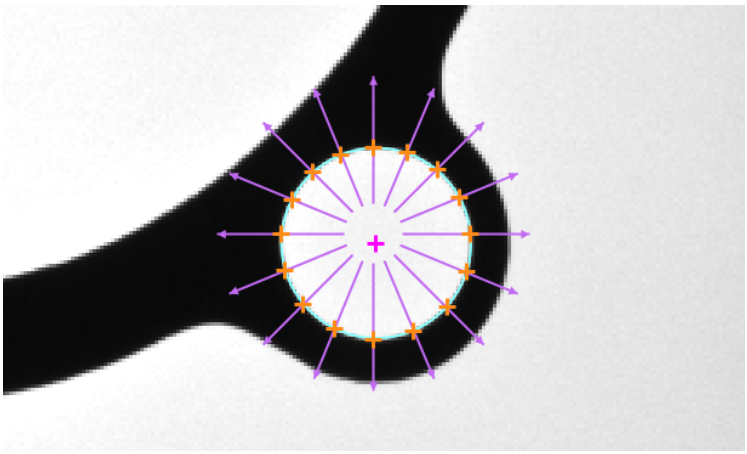
Description

The operation tries to fit a given circle to edges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleEdge_Direct filter along **inScanCount** specific scan segments which length is always equal to the **inFittingField** width and cannot be less than 4. The found points are then used to determine the actual position of the circle in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outCircle** is set to Nil.

Hints

- Connect an input image to the **inImage** input.
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no or too few edge points are found, try decreasing **inEdgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- If some of the scans may produce false results, try different values of the **inOutlierSuppression** input.
- Use the **outEdges** outputs to visualize the scanning results.

Examples



Fitting a circles to the edges of a hole
*(**inEdgeScanParams.Transition** = BrightToDark).*

Remarks

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outRidges**, **outDeviationProfile**, **outInliers**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

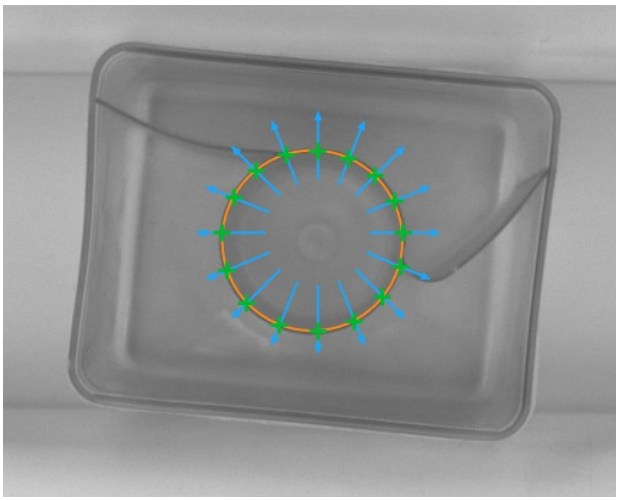
Description

The operation tries to fit a given circle to ridges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleRidge filter using **inFittingMap** previously generated from the object being fitted. The found points are then used to determine the actual position of the circle in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outCircle** is set to Nil.

Hints

- Connect an input image to the **inImage** input.
- Define **inRidgeScanParams.RidgePolarity** to detect a particular ridge type, and only that type.
- Adjust **inRidgeScanParams.RidgeWidth** to the expected thickness of the ridge (in pixels).
- If no or too few ridge points are found, try decreasing **inRidgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- If some of the scans may produce false results, try different values of the **inOutlierSuppression** input.
- Use the **outRidges** outputs to visualize the scanning results.

Examples



Fitting a circle to a wall of a plastic capsule
*(**inRidgeScanParams.Polarity** = Dark, **inRidgeScanParams.RidgeWidth** = 3).*

FitContour_Adaptive_Experimental

Header: AVL.h
Namespace: avl

Fits the given contour to the edges of the input image.

Syntax

```
void avl::FitContour_Adaptive_Experimental
(
 const avl::Image& inImage,
 const avl::Path& inExpectedContour,
 int inMaxDeviation,
 float inMaxSlant,
 int inStep,
 avl::EdgeTransition::Type inEdgeTransition,
 int inMinEdgeMagnitude,
 int inMaxEdgeMagnitude,
 float inGammaFactor,
 avl::InterpolationMethod::Type inInterpolationMethod,
 float inSmoothingStdDev,
 avl::Path& outContour,
 avl::Image& diagEdgeImage,
 avl::Path& diagEdgeContour
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inExpectedContour	const Path&			
➡	inMaxDeviation	int	1 – ∞	15	Maximal distance between the fitted and the expected contours
➡	inMaxSlant	float	1.0 – 60.0	45.0f	Maximal angle between corresponding tangents of the fitted and the expected contours
➡	inStep	int	1 – ∞	6	Distance between consecutive fitted points measured along the expected contour
➡	inEdgeTransition	EdgeTransition::Type			
➡	inMinEdgeMagnitude	int	0 – 255	0	
➡	inMaxEdgeMagnitude	int	0 – 255	255	
➡	inGammaFactor	float	0.01 – 10.0	1.0f	
➡	inInterpolationMethod	InterpolationMethod::Type			
➡	inSmoothingStdDev	float	0.0 – ∞	0.0f	
⬅	outContour	Path&			
🔍	diagEdgeImage	Image&			
🔍	diagEdgeContour	Path&			

FitPathToEdges

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Performs a series of 1D edge detections and creates a path from the detected points.

Applications: Tracing of an object contour, whose rough location and shape is known beforehand.

Syntax

```
void avl::FitPathToEdges
(
 const avl::Image& inImage,
 const PathFittingMap& inFittingMap,
 const EdgeScanParams& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxInterpolationLength,
 atl::Optional<float> inMaxDeviationDelta,
 float inMaxIncompleteness,
 atl::Conditional<avl::Path>& outPath,

 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit the path to
→	inFittingMap	const PathFittingMap&			Input fitting map
→	inEdgeScanParams	const EdgeScanParams&			Parameters controlling the edge extraction process
→	inEdgeSelection	Selection::Type		Selection::Best	Selection mode of edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxInterpolationLength	Optional<int>	0 – ∞	NIL	Maximal number of consecutive points not found
→	inMaxDeviationDelta	Optional<float>	0.0 – ∞	NIL	Maximal difference between deviations of consecutive path points
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of edge points not found
←	outPath	Conditional<Path>&			Fitted path or nothing if the fitting failed
←	outEdges	Optional<Array<Conditional<Edge1D>>&>		NIL	Found edges
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual path points and the corresponding reference path points
←	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Description

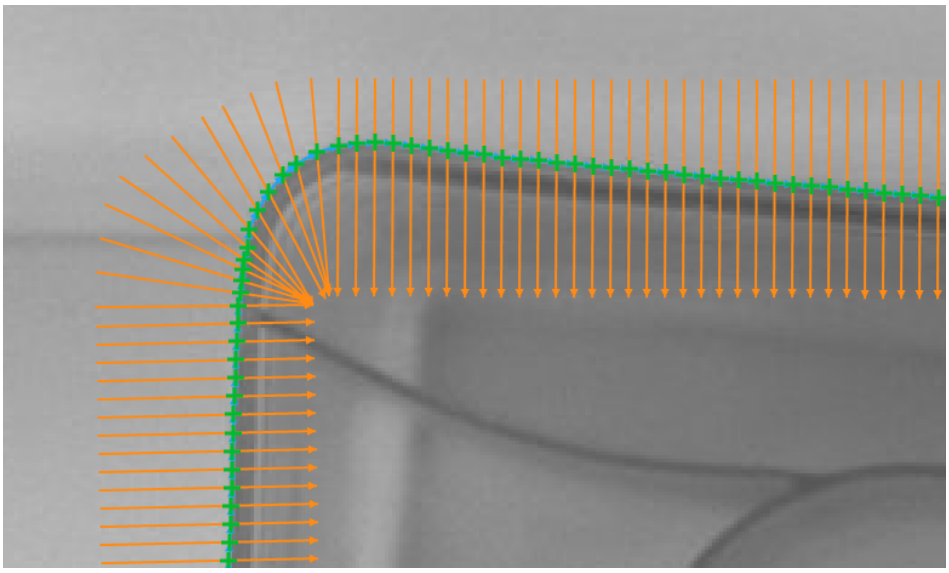
The operation tries to fit a given path to edges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleEdge filter using **inFittingMap** previously generated from the object being fitted. The found points are then used to determine the actual position of the path in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outPath** is set to Nil.

There are also another parameters that control the path fitting process. The **inMaxDeviationDelta** parameter defines the maximal allowed difference between deviations of consecutive points from the input path points. If some of the scans fail or if some of found points are classified to be wrong according to another control parameters, output path points corresponding to them are interpolated depending on points in their nearest vicinity. No more than **inMaxInterpolationLength** consecutive points can be interpolated. The exception to this behavior are points which were not found on both ends of the input path. Those are not part of the result at all.

Hints

- Connect an input image to the **inImage** input.
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no or too few edge points are found, try decreasing **inEdgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- Use the **outEdges** outputs to visualize the scanning results.

Examples



*Fitting a path to the edges of a plastic capsule (**inEdgeSelection** = First, **inEdgeScanParams.EdgeTransition** = BrightToDark).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the Shape Fitting toolset. To read more about this technique, one can refer to the Shape Fitting chapter of our Machine Vision Guide

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outEdges**, **outDeviationProfile**, **outAlignedFittingField**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Description

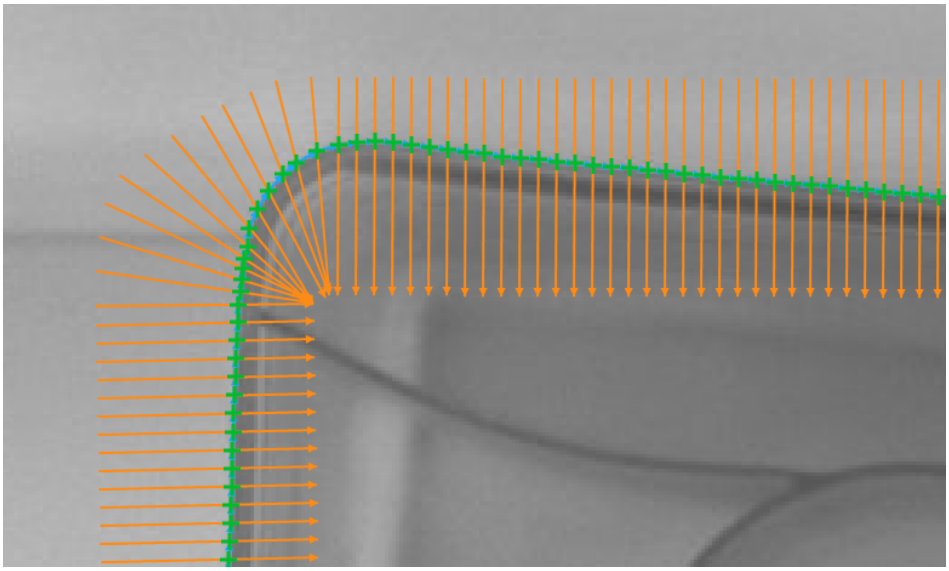
The operation tries to fit a given path to edges present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleEdge_Direct filter along a number of specific scan segments which length is always equal to the **inFittingField** width and cannot be less than 4. The found points are then used to determine the actual position of the path in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outPath** is set to Nil.

There are also another parameters that control the path fitting process. The **inMaxDeviationDelta** parameter defines the maximal allowed difference between deviations of consecutive points from the input path points. If some of the scans fail or if some of found points are classified to be wrong according to another control parameters, output path points corresponding to them are interpolated depending on points in their nearest vicinity. No more than **inMaxInterpolationLength** consecutive points can be interpolated. The exception to this behavior are points which were not found on both ends of the input path. Those are not part of the result at all.

Hints

- Connect an input image to the **inImage** input.
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no or too few edge points are found, try decreasing **inEdgeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- Use the **outEdges** outputs to visualize the scanning results.

Examples



Fitting a path to the edges of a plastic capsule
*(**inEdgeSelection** = First, **inEdgeScanParams.EdgeTransition** = BrightToDark).*

⬅	outAlignedFittingField	Optional<PathFittingField&>		NIL	Fitting field used; in the image coordinate system
⬅	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
⬅	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDeviationProfile**, **outAlignedFittingField**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

Description

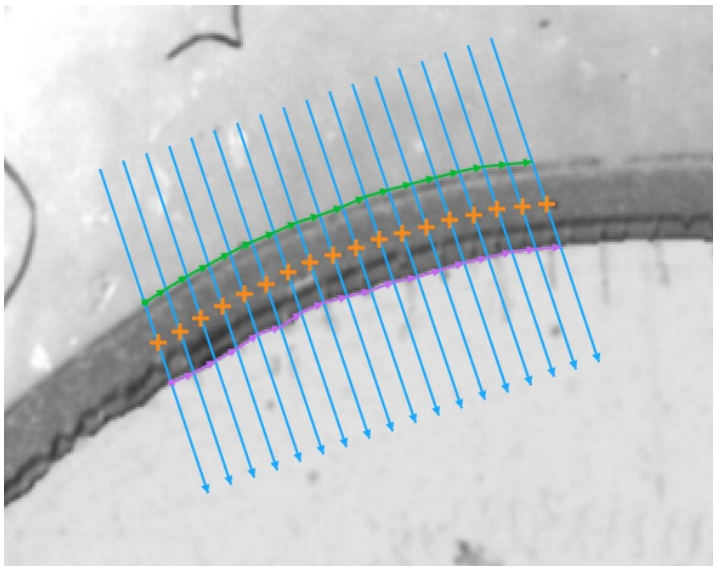
The operation tries to fit a given path to stripe present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleStripe_Direct filter along a number of specific scan segments which length is always equal to the **inFittingField** width and cannot be less than 4. The found points are then used to determine the actual position of the path in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outPath** is set to Nil.

There are also another parameters that control the path fitting process. The **inMaxDeviationDelta** parameter defines the maximal allowed difference between deviations of consecutive points from the input path points. If some of the scans fail or if some of found points are classified to be wrong according to another control parameters, output path points corresponding to them are interpolated depending on points in their nearest vicinity. No more than **inMaxInterpolationLength** consecutive points can be interpolated. The exception to this behavior are points which were not found on both ends of the input path. Those are not part of the result at all.

Hints

- Connect an input image to the **inImage** input.
- Define **inStripeScanParams.StripePolarity** to detect a particular stripe type, and only that type.
- Adjust **inStripeScanParams.MinStripeWidth** and **inStripeScanParams.MaxStripeWidth** to the expected thickness of the stripe (in pixels).
- If no or too few stripe points are found, try decreasing **inStripeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- Use the **outStripes** outputs to visualize the scanning results.

Examples



Fitting a path to a dark stripe
*(**inStripeScanParams.SmoothingStdDev** = 2.0, **inStripeScanParams.MinStripeWidth** = 15.0,*
***inStripeScanParams.StripePolarity** = Dark).*

Remarks

FitSegmentToEdges

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Performs a series of 1D edge detections and finds a segment that best matches the detected points.

Applications: Precise detection of a straight edge, whose rough location is known beforehand.

Syntax

```
void avl::FitSegmentToEdges
(
 const avl::Image& inImage,
 const avl::SegmentFittingMap& inFittingMap,
 const EdgeScanParams& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 float inMaxIncompleteness,
 atl::Optional<avl::LineMEstimator::Type> inOutlierSuppression,
 atl::Conditional<avl::Segment2D>& outSegment,
 atl::Optional<atl::Array<atl::Conditional<avl::Edge1D>>&> outEdges = atl::NIL,
 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,

 atl::Optional<atl::Conditional<avl::Profile>&> outDeviationProfile = atl::NIL,
 atl::Optional<avl::SegmentFittingField&> outAlignedFittingField = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outBrightnessProfiles = atl::NIL,
 atl::Optional<atl::Array<avl::Profile>&> outResponseProfiles = atl::NIL,
 atl::Array<avl::Segment2D>& diagScanSegments,
 atl::Array<avl::Rectangle2D>& diagSamplingAreas
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to fit segment to
→	inFittingField	const SegmentFittingField&			Segment fitting field
→	inFittingFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the fitting field to the position of the inspected object
→	inScanCount	int	3 – ∞	10	The number of points that will be searched to estimate the position of the segment
→	inScanWidth	int	1 – ∞	5	The width of each scan field (in pixels)
→	inSamplingParams	const SamplingParams&			Parameters controlling the sampling process
→	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inStripeSelection	Selection::Type			Selection mode of stripe
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxIncompleteness	float	0.0 – 0.999	0.1f	Maximal fraction of stripe points not found
→	inOutlierSuppression	Optional<LineMEstimator::Type>		NIL	Selects a method for ignoring incorrectly detected points
←	outSegment	Conditional<Segment2D>&			Fitted segment in the middle of found stripe
←	outLeftSegment	Conditional<Segment2D>&			Fitted left segment
←	outRightSegment	Conditional<Segment2D>&			Fitted right segment
←	outStripes	Optional<Array<Conditional<Stripe1D>>&>		NIL	Found stripes
←	outStripePoints	Optional<Array<Point2D>&>		NIL	Extracted points of middle segment of an image stripe
←	outDeviationProfile	Optional<Conditional<Profile>&>		NIL	Profile of distances between the actual segment points and the corresponding reference segment points
←	outAlignedFittingField	Optional<SegmentFittingField&>		NIL	Fitting field used; in the image coordinate system
←	outBrightnessProfiles	Optional<Array<Profile>&>		NIL	Extracted image profiles
←	outResponseProfiles	Optional<Array<Profile>&>		NIL	Profiles of the edge (derivative) operator response
🔍	diagScanSegments	Array<Segment2D>&			Segments along which the scans were run
🔍	diagSamplingAreas	Array<Rectangle2D>&			Areas from which the input image is sampled

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outStripes**, **outStripePoints**, **outDeviationProfile**, **outAlignedFittingField**, **outBrightnessProfiles**, **outResponseProfiles**.

Read more about Optional Outputs.

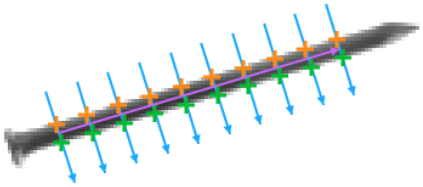
Description

The operation tries to fit a given segment to stripe present in the **inImage** image. Internally, it performs a series of scans with the ScanSingleStripe_Direct filter along **inScanCount** specific scan segments which length is always equal to the **inFittingField** width and cannot be less than 4. The found points are then used to determine the actual position of the segment in the image. Only **inMaxIncompleteness** fraction of these scans may fail. If the fitting according to the given parameters is not possible, **outSegment** is set to Nil.

Hints

- Connect an input image to the **inImage** input.
- Define **inStripeScanParams.StripePolarity** to detect a particular stripe type, and only that type.
- Adjust **inStripeScanParams.MinStripeWidth** and **inStripeScanParams.MaxStripeWidth** to the expected thickness of the stripe (in pixels).
- If no or too few stripe points are found, try decreasing **inStripeScanParams.MinMagnitude**.
- If some of the scans may fail, set the **inMaxIncompleteness** input accordingly.
- If some of the scans may produce false results, try different values of the **inOutlierSuppression** input.
- Use the **outStripePoints** outputs to visualize the scanning results.

Examples



Fitting a segment to the dark stripe of a nail
*(**inStripeScanParams.Polarity** = Dark).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the Shape Fitting toolset. To read more about this technique, one can refer to the Shape Fitting chapter of our Machine Vision Guide

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- CreateSegmentFittingMap – Precomputes a data object that is required for fast segment fitting on images.
- FitSegmentToEdges_Direct – Performs a series of 1D edge detections and finds a segment that best matches the detected points.
- FitSegmentToRidges_Direct – Performs a series of 1D ridge detections and finds a segment that best matches the detected points.
- FitSegmentToStripe – Performs a series of 1D stripe detections and finds a segment that best matches the detected points.

ImageShortestPath_Experimental

Header: AVL.h
Namespace: avl

Syntax

```
void avl::ImageShortestPath_Experimental
(
 const avl::Image& inImage,
 int inMarginX,
 int inMarginY,
 int inStep,
 float inMaxAngleDeviation,
 avl::InterpolationMethod::Type inMethod,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inMarginX	int			
→	inMarginY	int			
→	inStep	int	1 – ∞	5	
→	inMaxAngleDeviation	float	0.0 – 90.0	45.0f	
→	inMethod	InterpolationMethod::Type			
←	outPath	Path&			Output path

CreateBoxBorderRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a frame-shaped region with given parameters.

Syntax

```
void avl::CreateBoxBorderRegion
(
 const avl::Box& inBox,
 int inBorderWidth,
 avl::BorderPosition::Type inBorderPosition,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			
→	inBorderWidth	int	0 – ∞	1	
→	inBorderPosition	BorderPosition::Type		Centered	
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect BorderPosition in CreateBoxBorderRegion.

CreateBoxRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a rectangular region corresponding to a given box.

Syntax

```
void avl::CreateBoxRegion
(
 const avl::Box& inBox,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBox	const Box&			A box defining pixels that will be converted to white elements
→	inFrameWidth	int	0 – 65535		Width of the created region's frame (not to be confused with the width of the box!)
→	inFrameHeight	int	0 – 65535		Height of the created region's frame (not to be confused with the height of the box!)
←	outRegion	Region&			Output region

Description

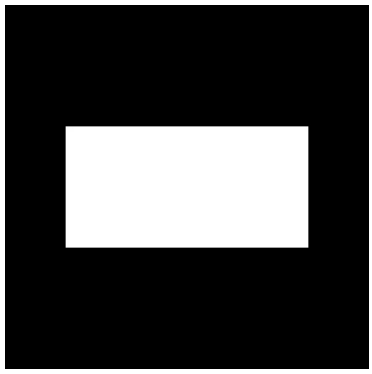
The operation creates a region containing pixels lying inside the **inBox**.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input box exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



***CreateBoxRegion** run with **inBox** = Box(50,100,200,100).*

See Also

- CreateEllipseRegion – Creates an elliptic region of given bounding rectangle.
- CreatePolygonRegion – Creates a polygonal region corresponding to a given closed path.

CreateCircleRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a circular region corresponding to a given circle.

Syntax

```
void avl::CreateCircleRegion
(
 const avl::Circle2D& inCircle,
 atl::Optional<const avl::CoordinateSystem2D&> inCircleAlignment,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Circle2D&> outAlignedCircle = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCircle	const Circle2D&			
→	inCircleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the circle to the position of the inspected object
→	inFrameWidth	int	0 – 65535		Width of the created region's frame (not to be confused with the size of the circle!)
→	inFrameHeight	int	0 – 65535		Height of the created region's frame (not to be confused with the size of the circle!)
←	outRegion	Region&			Output region
←	outAlignedCircle	Optional<Circle2D&>		NIL	The input circle transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedCircle**.

Read more about Optional Outputs.

Description

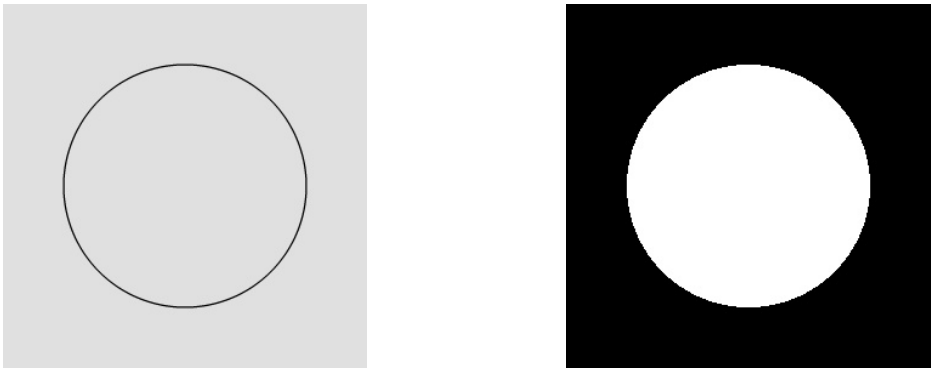
The operation creates a region containing pixels lying inside the given circle.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input circle exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



CreateCircleRegion *run with* ***inCircle*** *= Circle2D(150,150,100).*

See Also

- CreateEllipseRegion – Creates an elliptic region of given bounding rectangle.

CreateCrossRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a cross-shaped region with given parameters.

Syntax

```
void avl::CreateCrossRegion
(
 const avl::Box& inCrossBoundingBox,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCrossBoundingBox	const Box&			
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region

Description

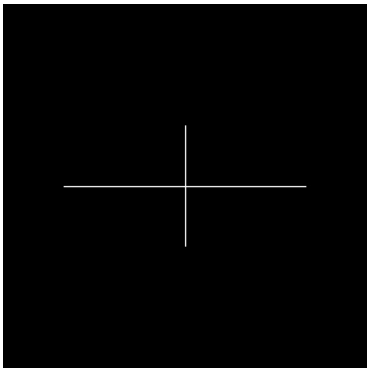
The operation creates a region in a shape of a one-pixel-wide cross. Cross is described by its width, height and coordinates of upper-left corner of its bounding box.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input cross exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



CreateCrossRegion *run with* ***inCrossBoundingBox*** *parameters:* ***X*** *= 50,* ***Y*** *= 100,* ***Width*** *= 200,* ***inCrossHeight*** *= 100.*

See Also

- CreateBoxRegion – Creates a rectangular region corresponding to a given box.
- CreatePolygonRegion – Creates a polygonal region corresponding to a given closed path.

CreateEllipseRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an elliptic region of given bounding rectangle.

Syntax

```
void avl::CreateEllipseRegion
(
 const avl::Rectangle2D& inEllipse,
 atl::Optional<const avl::CoordinateSystem2D&> inEllipseAlignment,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Rectangle2D&> outAlignedEllipse = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inEllipse	const Rectangle2D&			
→	inEllipseAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the ellipse to the position of the inspected object
→	inFrameWidth	int	0 – 65535		Width of the created region's frame (not to be confused with the width of the ellipse!)
→	inFrameHeight	int	0 – 65535		Height of the created region's frame (not to be confused with the height of the ellipse!)
←	outRegion	Region&			Output region
←	outAlignedEllipse	Optional<Rectangle2D&>		NIL	The input ellipse transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedEllipse**.

Read more about Optional Outputs.

Description

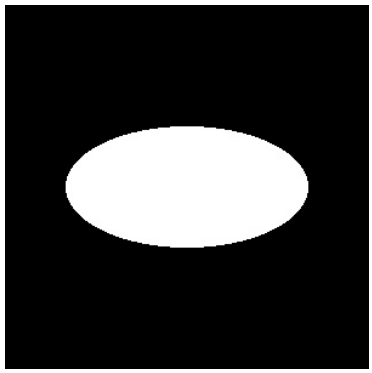
The operation creates a region containing pixels lying inside an ellipse which is described by its bounding rectangle.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input ellipse exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



***CreateEllipseRegion** run with a sample rectangle.*

See Also

- CreateCircleRegion – Creates a circular region corresponding to a given circle.

CreateGridRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a grid-shaped region with given parameters.

Syntax

```
void avl::CreateGridRegion
(
 const avl::Box& inGridBoundingBox,
 int inHorizontalStep,
 int inVerticalStep,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inGridBoundingBox	const Box&			
→	inHorizontalStep	int	1 – ∞		Horizontal distance between vertical grid lines.
→	inVerticalStep	int	1 – ∞		Vertical distance between horizontal grid lines.
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region

Description

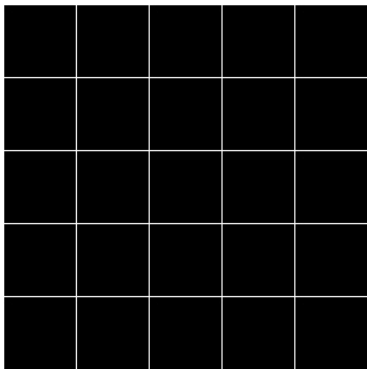
The operation creates a region in a shape of a one-pixel-wide grid. Grid is described by its width, height, distances between its lines and coordinates of its upper-left corner.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



CreateGridRegion *run with* ***inGridBoundingBox*** *parameters:* ***X*** *= 0,* ***Y*** *= 0,* ***inGridWidth*** *= 300,* ***inGridHeight*** *= 300 and with* ***inHorizontalStep*** *= 60,* ***inVerticalStep*** *= 60*

See Also

- CreateBoxRegion – Creates a rectangular region corresponding to a given box.
- CreateCrossRegion – Creates a cross-shaped region with given parameters.

CreateLineRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a line region.

Syntax

```
void avl::CreateLineRegion
(
 const avl::Line2D& inLine,
 atl::Optional<const avl::CoordinateSystem2D&> inLineAlignment,
 float inWidth,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Line2D&> outAlignedLine = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLine	const Line2D&			
→	inLineAlignment	Optional<const CoordinateSystem2D&>		NIL	
→	inWidth	float	1.0 – ∞		Width of output region line
→	inFrameWidth	int	0 – 65535		
→	inFrameHeight	int	0 – 65535		
←	outRegion	Region&			Output region
←	outAlignedLine	Optional<Line2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedLine**.

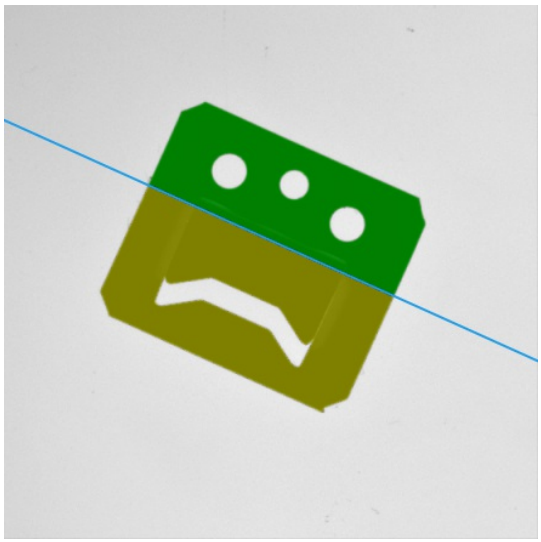
Read more about Optional Outputs.

Description

Filter creates a region defined by an input Line2D with width of **inWidth**.

Examples

Filter CreateLineRegion is used to split region int two parts:



CreatePathBorderRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a region along a given path. The region may be internal or external to the path.

Syntax

```
void avl::CreatePathBorderRegion
(
 const avl::Path& inPath,
 atl::Optional<const avl::CoordinateSystem2D&> inPathAlignment,
 float inBorderWidth,
 avl::BorderPosition::Type inBorderPosition,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Path&> outAlignedPath = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the path to the position of the inspected object
→	inBorderWidth	float	1.0 – ∞	1.0f	
→	inBorderPosition	BorderPosition::Type		Centered	
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedPath	Optional<Path&>		NIL	The input path transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedPath**.

Read more about Optional Outputs.

CreatePathRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a region along the given path.

Syntax

```
void avl::CreatePathRegion
(
 const avl::Path& inPath,
 atl::Optional<const avl::CoordinateSystem2D&> inPathAlignment,
 float inWidth,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Path&> outAlignedPath = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the path to the position of the inspected object
