→	inWidth	float	1.0 – ∞	1.0f	Width of line used to draw path
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedPath	Optional<Path&>		NIL	The input path transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedPath**.

Read more about Optional Outputs.

Also in AVL Lite

CreatePolygonRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a polygonal region corresponding to a given closed path.

Syntax

```
void avl::CreatePolygonRegion
(
 const avl::Path& inPolygon,
 atl::Optional<const avl::CoordinateSystem2D&> inPolygonAlignment,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Path&> outAlignedPolygon = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPolygon	const Path&			
→	inPolygonAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the polygon to the position of the inspected object
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedPolygon	Optional<Path&>		NIL	The input polygon transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedPolygon**.

Read more about Optional Outputs.

Description

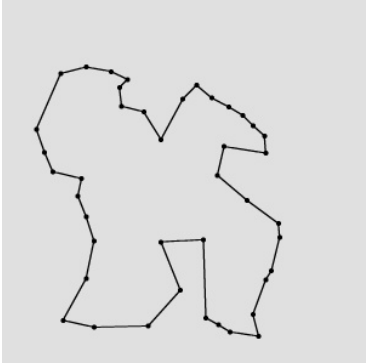
The operation creates a region containing pixels lying inside the shape described by **inPolygon**.

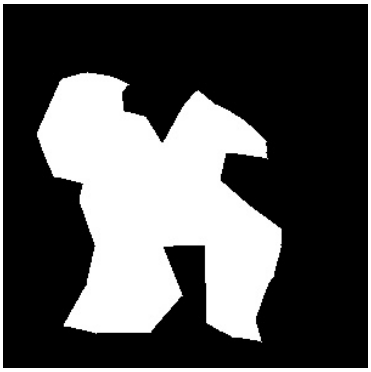
The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input polygon exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples





Remarks

- **inPolygon** has to be a closed path, otherwise an error with appropriate description occurs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Open path on input in CreatePolygonRegion.

See Also

- CreateBoxRegion – Creates a rectangular region corresponding to a given box.
- CreateCrossRegion – Creates a cross-shaped region with given parameters.

CreateRectangleBorderRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a frame-shaped region with given parameters.

Syntax

```
void avl::CreateRectangleBorderRegion
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 float inBorderWidth,
 avl::BorderPosition::Type inBorderPosition,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Rectangle2D&> outAlignedRectangle = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			
→	inRectangleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the rectangle to the position of the inspected object
→	inBorderWidth	float	0.0 – ∞	1.0f	
→	inBorderPosition	BorderPosition::Type		Centered	
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedRectangle	Optional<Rectangle2D&>		NIL	The input rectangle transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRectangle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect BorderPosition in CreateRectangleBorderRegion.

CreateRectangleRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a region corresponding to a given rectangle.

Syntax

```
void avl::CreateRectangleRegion
(
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Rectangle2D&> outAlignedRectangle = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRectangle	const Rectangle2D&			
→	inRectangleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the rectangle to the position of the inspected object
→	inFrameWidth	int	0 – 65535		Width of the created region's frame (not to be confused with the width of the rectangle!)
→	inFrameHeight	int	0 – 65535		Height of the created region's frame (not to be confused with the height of the rectangle!)
←	outRegion	Region&			Output region
←	outAlignedRectangle	Optional<Rectangle2D&>		NIL	The input rectangle transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRectangle**.

Read more about Optional Outputs.

Description

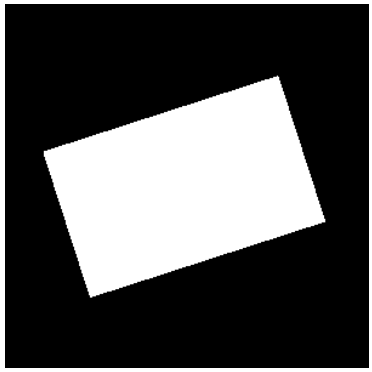
The operation creates a region containing pixels lying inside the specified rectangle.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with. If the input rectangle exceeds these dimensions, the output region will be cropped.

Hints

- Remember to set **inFrameWidth** and **inFrameHeight** inputs to specify the region frame.

Examples



See Also

- CreateCircleRegion – Creates a circular region corresponding to a given circle.

CreateRingRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a ring-shaped region with given parameters.

Syntax

```
void avl::CreateRingRegion
(
 const avl::Circle2D& inCircle,
 atl::Optional<const avl::CoordinateSystem2D&> inCircleAlignment,
 float inRingWidth,
 avl::BorderPosition::Type inBorderPosition,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion,
 atl::Optional<avl::Circle2D&> outAlignedCircle = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inCircle	const Circle2D&			Input circle
→	inCircleAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the circle to the position of the inspected object
→	inRingWidth	float	0.0 – ∞	1.0f	
→	inBorderPosition	BorderPosition::Type		Centered	
→	inFrameWidth	int	0 – 65535		Width of the created region's frame
→	inFrameHeight	int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region
←	outAlignedCircle	Optional<Circle2D&>		NIL	The input circle transformed to the absolute coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedCircle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect BorderPosition in CreateRingRegion.

CreateSegmentRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates a segment region.

Syntax

```
void avl::CreateSegmentRegion
(
 const avl::Segment2D& inSegment,
 atl::Optional<const avl::CoordinateSystem2D&> inSegmentAlignment,
 float inWidth,
 int inFrameWidth,
 int inFrameHeight,
 bool inRound,
 avl::Region& outRegion,
 atl::Optional<avl::Segment2D&> outAlignedSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment	const Segment2D&			
→	inSegmentAlignment	Optional<const CoordinateSystem2D&>		NIL	
→	inWidth	float	1.0 – ∞		Segment width
→	inFrameWidth	int	0 – 65535		
→	inFrameHeight	int	0 – 65535		
→	inRound	bool			Make ends of segment round
←	outRegion	Region&			Output region
←	outAlignedSegment	Optional<Segment2D&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedSegment**.

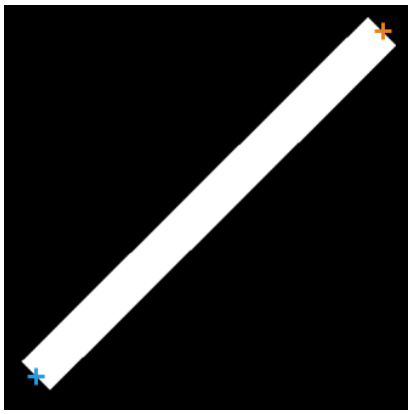
Read more about Optional Outputs.

Description

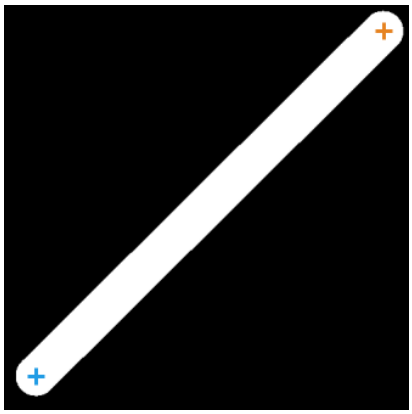
Filter creates region based on an input Segment2D. To specify line width use **inWidth**.

Filter creates segment region by creating rectangle located between **inSegment** points. To make ends round use **inRound**.

Examples



Example region with **inRound**=False



Example region with **inRound**=True

Also in AVL Lite

EmptyRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Creates an empty region with a given frame.

Syntax

```
void avl::EmptyRegion
(
 const int inFrameWidth,
 const int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inFrameWidth	const int	0 – 65535		Width of the created region's frame
→	inFrameHeight	const int	0 – 65535		Height of the created region's frame
←	outRegion	Region&			Output region

Also in AVL Lite

GetRegionFrame

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the width and height of the entire region's frame (not to be confused with RegionBoundingBox!).

Syntax

```
void avl::GetRegionFrame
(
 const avl::Region& inRegion,
 int& outFrameWidth,
 int& outFrameHeight
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outFrameWidth	int&		
←	outFrameHeight	int&		

LocationsToRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Forms a region containing pixels of given locations.

Syntax

```
void avl::LocationsToRegion
(
 const atl::Array<avl::Location>& inLocations,
 int inFrameWidth,
 int inFrameHeight,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLocations	const Array<Location>&			
→	inFrameWidth	int	0 – 65535		
→	inFrameHeight	int	0 – 65535		
←	outRegion	Region&			Output region

Description

The operation forms a region equivalent to the given array of pixel locations. If any of the parameters **inFrameWidth**, **inFrameHeight** is not provided, it is set to the smallest value that allows to contain all locations inside of the region.

The **inFrameWidth** and **inFrameHeight** parameters most often should be set equal to the dimensions of the image this region will be used with.

See Also

- RegionToLocations – Converts a region to an array of its pixel locations.

RegionCharacteristicPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns a characteristic point of the input's region bounding box.

Syntax

```
void avl::RegionCharacteristicPoint
(
 const avl::Region& inRegion,
 const avl::Anchor2D::Type inPointAnchor,
 avl::Point2D& outPoint
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inPointAnchor	const Anchor2D::Type	TopLeft	
←	outPoint	Point2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionCharacteristicPoint.

Also in AVL Lite

RegionToLocations

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a region to an array of its pixel locations.

Applications: It may be considered explicit region decompression.

Syntax

```
void avl::RegionToLocations
(
 const avl::Region& inRegion,
 atl::Array<avl::Location>& outLocations
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outLocations	Array<Location>&		

Description

The operation forms an array of pixel locations equivalent to the given region. Note that the resulting array may occupy much more space than the region because it stores each pixels separately, as opposed to the run-length encoding used in regions.

See Also

- LocationsToRegion – Forms a region containing pixels of given locations.

SetRegionFrame

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes the width and the height of a region's frame (but does not rescale the content).

Syntax

```
void avl::SetRegionFrame
(
 avl::Region& ioRegion,
 int inWidth,
 int inHeight
)
```

Parameters

	Name	Type	Range	Default	Description
	ioRegion	Region&			
	inWidth	int	0 – 65535		New frame width
	inHeight	int	0 – 65535		New frame height

Description

The operation sets the region frame's width and height to new values, while it does **not** change the location of any of the region pixels. Note that all of the region pixels have to be contained within region frame's dimensions. If this is not the case with selected dimensions, an error with appropriate description occurs.

Examples

SetRegionFrame *used to change dimensions from 150x150 to 300x300.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Resulting region isn't contained in new dimensions in SetRegionFrame.

See Also

- CropRegion – Creates a region from a rectangular fragment of another one.

Also in AVL Lite

SkipEmptyRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

If the input region contains at least one pixel, then it is copied to the output; otherwise Nil is returned.

Applications: Secures against domain errors caused by empty regions, e.g. just before the RegionMassCenter filter is to be invoked.

Syntax

```
void avl::SkipEmptyRegion
(
 const avl::Region& inRegion,
 atl::Conditional<avl::Region>& outNotEmptyRegion,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outNotEmptyRegion	Conditional<Region>&		
←	outIsNotEmpty	bool&		

Also in AVL Lite

TestRegionEmpty

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether the size of a region equals zero.

Syntax

```
void avl::TestRegionEmpty
(
 const avl::Region& inRegion,
 bool& outIsEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outIsEmpty	bool&		

TestRegionNotEmpty

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether the size of a region doesn't equal zero.

Syntax

```
void avl::TestRegionNotEmpty
(
 const avl::Region& inRegion,
 bool& outIsNotEmpty
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outIsNotEmpty	bool&		

TestRegionOnBorder

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a region is adjacent to its border.

Syntax

```
void avl::TestRegionOnBorder
(
 const avl::Region& inRegion,
 bool& outIsOnBorder
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outIsOnBorder	bool&		

Description

Tests whether a region is adjacent to its border.

Examples

Filter output	Region preview image
False	True	
VerifyRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Checks if the point-runs of the input region are correctly arranged (sorted, not overlapping etc.).

Applications: You only need to use this tool if you create regions from point-runs manually.

Syntax

```
void avl::VerifyRegion
(
 const avl::Region& inRegion
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region

Errors

List of possible exceptions:

Error type	Description
DomainError	Input region's dimension is negative in VerifyRegion.
DomainError	Input region's PointRun end has invalid X coordinate in VerifyRegion.
DomainError	Input region's PointRun has invalid Y coordinate in VerifyRegion.
DomainError	Input region's PointRun is empty in VerifyRegion.
DomainError	Input region's PointRuns are not sorted in VerifyRegion.
DomainError	Input region's size is negative in VerifyRegion.

76. Data Classification Common

Table of content:

- CreateDataPartition
- MeasureClassificationQuality_Binary
- MeasureClassificationQuality_Multiclass

CreateDataPartition

Header: AVL.h
Namespace: avl
Module: FoundationPro

Divides the input set to test and train subsets, trying to maintain balance in class distribution.

Syntax

```
void avl::CreateDataPartition
(
 const atl::Array<atl::Array<float>>& inFeatureSet,
 const atl::Array<int>& inClassAssignment,
 const float inTestToTrainingRatio,
 const int inRandomSeed,
 atl::Array<atl::Array<float>>& outTrainSet,
 atl::Array<atl::Array<float>>& outTrainResponse,
 atl::Array<atl::Array<float>>& outTestSet,
 atl::Array<atl::Array<float>>& outTestResponse
)
```

Parameters

	Name	Type	Range	Default	Description
→	inFeatureSet	const Array<Array<float>>&			
→	inClassAssignment	const Array<int>&			
→	inTestToTrainingRatio	const float	0.0 – 1.0	0.75f	
→	inRandomSeed	const int		0	
←	outTrainSet	Array<Array<float>>&			
←	outTrainResponse	Array<Array<float>>&			
←	outTestSet	Array<Array<float>>&			
←	outTestResponse	Array<Array<float>>&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of inFeatureSet and inClassAssignment arrays

MeasureClassificationQuality_Binary

Header: AVL.h
Namespace: avl
Module: FoundationPro

Calculates classification performance metrics for binary problems.

Syntax

```
void avl::MeasureClassificationQuality_Binary
(
 const atl::Array<bool>& inPredictedClasses,
 const atl::Array<bool>& inExpectedClasses,
 float& outAccuracy,
 float& outPrecision,
 float& outRecall,
 float& outF1Score,
 avl::Matrix& outConfusionMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inPredictedClasses	const Array<bool>&		
→	inExpectedClasses	const Array<bool>&		
←	outAccuracy	float&		
←	outPrecision	float&		
←	outRecall	float&		
←	outF1Score	float&		
←	outConfusionMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in MeasureClassificationQuality_Binary.
DomainError	Inconsistent array sizes on input in MeasureClassificationQuality_Binary.

MeasureClassificationQuality_Multiclass

Header: AVL.h
Namespace: avl
Module: FoundationPro

Calculates classification performance metrics for multiclass problems.

Syntax

```
void avl::MeasureClassificationQuality_Multiclass
(
 const atl::Array<int>& inPredictedClasses,
 const atl::Array<int>& inExpectedClasses,
 float& outAccuracy,
 atl::Array<float>& outPrecisions,
 atl::Array<float>& outRecalls,
 atl::Array<float>& outF1Scores,
 avl::Matrix& outConfusionMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inPredictedClasses	const Array<int>&		
→	inExpectedClasses	const Array<int>&		
←	outAccuracy	float&		
←	outPrecisions	Array<float>&		
←	outRecalls	Array<float>&		
←	outF1Scores	Array<float>&		
←	outConfusionMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Class designator must start at 0.
DomainError	Empty array on input in MeasureClassificationQuality_Multiclass.
DomainError	Inconsistent array sizes on input in MeasureClassificationQuality_Multiclass.

77. Image Tiling

Table of content:

- CreateImageTiles
- CreateImageTiles_AsBoxes
- CutImageIntoTiles
- EnumerateImageTiles
- JoinImageTiles

CreateImageTiles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Generates an array of regions and an array of boxes covering the area of an image.

Syntax

```
void avl::CreateImageTiles
(
 const avl::Size& inImageSize,
 const int inTileWidth,
 atl::Optional<int> inTileHeight,
 atl::Optional<int> inHorizontalStep,
 atl::Optional<int> inVerticalStep,
 const avl::OverflowControl::Type inOverflowControl,
 atl::Array<avl::Region>& outTileRegions,
 atl::Array<avl::Box>& outTileBoxes,
 int& outRowCount,
 int& outColumnCount
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageSize	const Size&			Format of image for which tiles will be produced.
→	inTileWidth	const int	1 – ∞	32	Demanded tile width.
→	inTileHeight	Optional<int>	1 – ∞	NIL	Demanded tile height; equals inTileWidth when set to Auto.
→	inHorizontalStep	Optional<int>	1 – ∞	NIL	Defines horizontal space between consecutive tiles; defaults to tile width. Can be used to produce overlapping tiles.
→	inVerticalStep	Optional<int>	1 – ∞	NIL	Defines vertical space between consecutive tiles; defaults to tile height. Can be used to produce overlapping tiles.
→	inOverflowControl	const OverflowControl::Type		KeepLast	Define what to do when overflowing tiles are present.
←	outTileRegions	Array<Region>&			Array containing produced tiles.
←	outTileBoxes	Array<Box>&			Array containing produced tiles.
←	outRowCount	int&			Number of generated tiles rows.
←	outColumnCount	int&			Number of generated tiles per row.

CreateImageTiles_AsBoxes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Generates an array of boxes covering the area of an image.

Syntax

```
void avl::CreateImageTiles_AsBoxes
(
 const avl::Size& inImageSize,
 const int inTileWidth,
 atl::Optional<int> inTileHeight,
 atl::Optional<int> inHorizontalStep,
 atl::Optional<int> inVerticalStep,
 const avl::OverflowControl::Type inOverflowControl,
 atl::Array<avl::Box>& outTileBoxes,
 int& outRowCount,
 int& outColumnCount
)
```

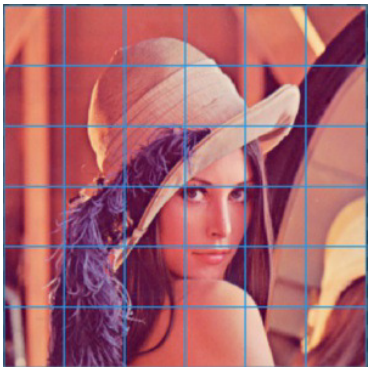
Parameters

	Name	Type	Range	Default	Description
→	inImageSize	const Size&			Format of image for which tiles will be produced.
→	inTileWidth	const int	1 – ∞	32	Demanded tile width.
→	inTileHeight	Optional<int>	1 – ∞	NIL	Demanded tile height; equals inTileWidth when set to Auto.
→	inHorizontalStep	Optional<int>	1 – ∞	NIL	Defines horizontal space between consecutive tiles; defaults to tile width. Can be used to produce overlapping tiles.
→	inVerticalStep	Optional<int>	1 – ∞	NIL	Defines vertical space between consecutive tiles; defaults to tile height. Can be used to produce overlapping tiles.
→	inOverflowControl	const OverflowControl::Type		KeepLast	Define what to do when overflowing tiles are present.
←	outTileBoxes	Array<Box>&			Array containing produced tiles.
←	outRowCount	int&			Number of generated tiles rows.
←	outColumnCount	int&			Number of generated tiles per row.

Description

Creates an array of boxes.

Examples



CreateImageTiles_asBoxes *with inTileWidth = 50 and inOverflowControl = true.*

See Also

- JoinImageTiles – Joins previously cut tiles into single image.
- CutImageIntoTiles – Generates an array of small images by cutting the input image.

CutImageIntoTiles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Generates an array of small images by cutting the input image.

Syntax

```
void avl::CutImageIntoTiles
(
 const avl::Image& inImage,
 const int inTileWidth,
 atl::Optional<int> inTileHeight,
 atl::Optional<int> inHorizontalStep,
 atl::Optional<int> inVerticalStep,
 const avl::OverflowControl::Type inOverflowControl,
 atl::Array<avl::Image>& outImageTiles
)
```

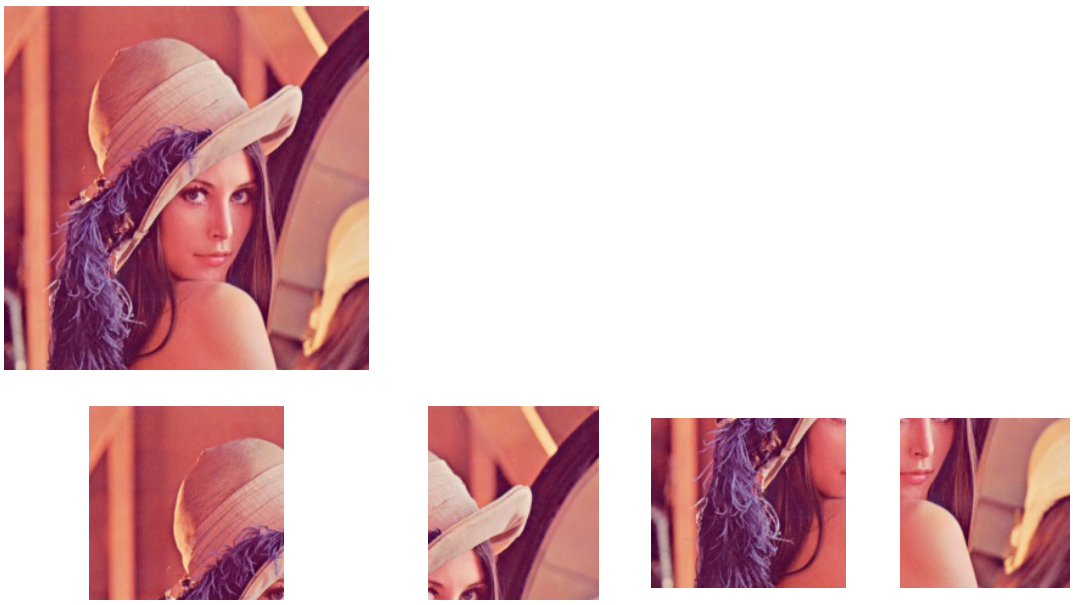
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image to be cut into tiles
→	inTileWidth	const int	1 – ∞	1	Demanded tile width.
→	inTileHeight	Optional<int>	1 – ∞	NIL	Demanded tile height; equals inTileWidth when set to Auto.
→	inHorizontalStep	Optional<int>	1 – ∞	NIL	Defines horizontal space between consecutive tiles; defaults to tile width. Can be used to produce overlapping tiles.
→	inVerticalStep	Optional<int>	1 – ∞	NIL	Defines vertical space between consecutive tiles; defaults to tile height. Can be used to produce overlapping tiles.
→	inOverflowControl	const OverflowControl::Type			Define what to do when overflowing tiles are present.
←	outImageTiles	Array<Image>&			Resulting image tiles

Description

Generates an array of image tiles, which are cut from inImage.

Examples



CutImageIntoTiles *performed on the sample image with* ***inOverflowControl*** *= false.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- JoinImageTiles – Joins previously cut tiles into single image.

EnumerateImageTiles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Enumerates tiles from image.

Syntax

```
bool avl::EnumerateImageTiles
(
 EnumerateImageTilesState& ioState,
 const avl::Image& inImage,
 int inTileWidth,
 atl::Optional<int> inTileHeight,
 bool inOverflowControl,
 const int inDelay,
 avl::Image& outTile,
 atl::Optional<bool&> outIsFirst = atl::NIL,
 atl::Optional<bool&> outIsLast = atl::NIL,
 avl::Box& diagTilePosition = atl::Dummy<avl::Box>()
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	EnumerateImageTilesState&			Object used to maintain state of the function.
	inImage	const Image&			Image to be enumerated
	inTileWidth	int	1 – ∞	1	Tile width
	inTileHeight	Optional<int>	1 – ∞	NIL	Tile height
	inOverflowControl	bool			Allow overflow
	inDelay	const int			Minimum time between iterations in milliseconds
	outTile	Image&			
	outIsFirst	Optional<bool&>		NIL	Flag indicating the first iteration
	outIsLast	Optional<bool&>		NIL	Flag indicating the last iteration
	diagTilePosition	Box&			Cut out tile position.

Optional Outputs

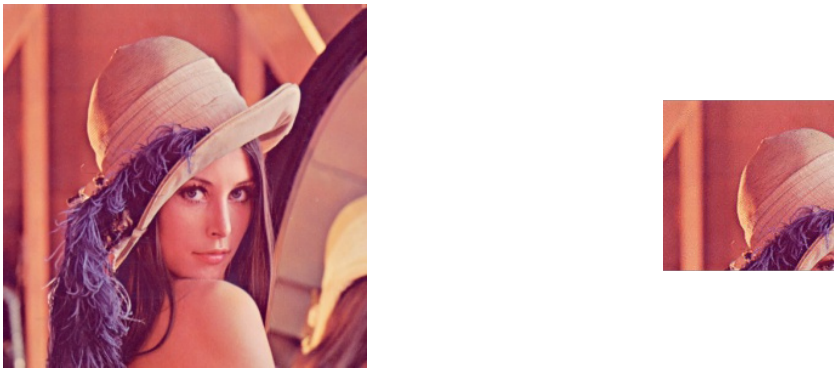
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

Description

Cuts out a tile from inImage and serves them one by one. Tile dimensions cannot be changed during image traversal.

Examples



EnumerateImageTiles *performed on the sample image with* ***inOverflowControl*** *= true.*

See Also

- JoinImageTiles – Joins previously cut tiles into single image.
- CutImageIntoTiles – Generates an array of small images by cutting the input image.
- JoinImageTiles – Joins previously cut tiles into single image.

JoinImageTiles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Joins previously cut tiles into single image.

Syntax

```
void avl::JoinImageTiles
(
 const atl::Array<avl::Image>& inImages,
 const int inRowCount,
 const int inColumnCount,
 avl::Image& outJoinedImage
)
```

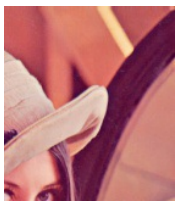
Parameters

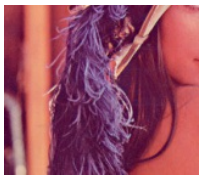
	Name	Type	Range	Default	Description
→	inImages	const Array<Image>&			Array of image tiles.
→	inRowCount	const int	1 – ∞		Defines how many output image rows there are in inImages.
→	inColumnCount	const int	1 – ∞		Defines how many images builds one row in inImages.
←	outJoinedImage	Image&			Glued image.

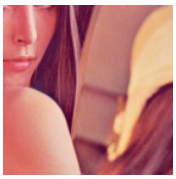
Description

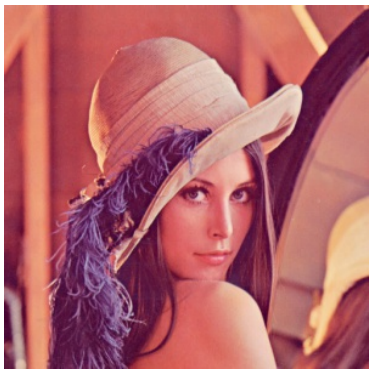
Joins an array of images into one image.

Examples









JoinImageTiles *glues together an array of images with inRowCount = 2 and inColumnCount = 2.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input images do not have compatible height in JoinImageTiles.
DomainError	Input images do not have compatible width in JoinImageTiles.
DomainError	Input images do not have the same pixel format in JoinImageTiles.
DomainError	Product of inRowCount and inColumnCount must be equal to size of inImages array in JoinImageTiles.

78. Geometry 2D Relations

Table of content:

- CreatePointGraph
- FindClosestPoints
- TestPointArrayInBox
- TestPointArrayInRectangle
- TestPointInBox
- TestPointInCircle
- TestPointInRectangle
- TestSegmentsIntersect

CreatePointGraph

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a graph of points that lie close to each other.

Syntax

```
void avl::CreatePointGraph
(
 const atl::Array<avl::Point2D>& inPoints,
 const int inMaxRank,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<float> inMaxRelativeDistance,
 atl::Array<atl::Array<int> >& outGraph,
 atl::Array<atl::Array<float> >& outDistances,
 atl::Array<avl::Segment2D>& diagSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoints	const Array<Point2D>&			Input points
→	inMaxRank	const int	1 – ∞	8	Maximum connections going out of one point
→	inMinDistance	float	0.0 – ∞	0.0f	Minimum distance between adjacent point in the graph
→	inMaxDistance	Optional<float>	0.0 – ∞	10.0f	Maximum distance between adjacent point in the graph
→	inMaxRelativeDistance	Optional<float>	1.0 – ∞	NIL	Maximum distance in relation to the shortest distance for a point
←	outGraph	Array<Array<int> >&			Graph of points (adjacency list)
←	outDistances	Array<Array<float> >&			Distances between adjacent points in the graph
🔍	diagSegments	Array<Segment2D>&			Graph edges, useful for visualization

Errors

List of possible exceptions:

Error type	Description
DomainError	Minimum distance is greater than maximum distance in CreatePointGraph.

FindClosestPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

For each given point, finds the closest point among the given point set.

Syntax

```
void avl::FindClosestPoints
(
 const atl::Array<avl::Point2D>& inPointSet,
 const atl::Array<avl::Point2D>& inQueries,
 atl::Array<avl::Point2D>& outPoints,
 atl::Array<int>& outIndices
)
```

Parameters

	Name	Type	Default	Description
→	inPointSet	const Array<Point2D>&		Points that will be searched.
→	inQueries	const Array<Point2D>&		
←	outPoints	Array<Point2D>&		For each point in inQueries, the closest point value from inPointSet.
←	outIndices	Array<int>&		For each point in inQueries, the closest point index of inPointSet.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Also in AVL Lite

TestPointArrayInBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests which points lie inside a box.

Syntax

```
void avl::TestPointArrayInBox
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Box& inBox,
 atl::Array<bool>& outIsContainedArray,
 atl::Optional<atl::Array<avl::Point2D>&> outPoints = atl::NIL,
 atl::Optional<bool&> outAreAllContained = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Points which will be tested
→	inBox	const Box&		
←	outIsContainedArray	Array<bool>&		
←	outPoints	Optional<Array<Point2D>&>	NIL	Points that are contained
←	outAreAllContained	Optional<bool&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPoints**, **outAreAllContained**.

Read more about Optional Outputs.

TestPointArrayInRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests which points lie inside a rectangle.

Syntax

```
void avl::TestPointArrayInRectangle
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Rectangle2D& inRectangle,
 atl::Array<bool>& outIsContainedArray,
 atl::Optional<atl::Array<avl::Point2D>&> outPoints = atl::NIL,
 atl::Optional<bool&> outAreAllContained = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Points which will be tested
→	inRectangle	const Rectangle2D&		
←	outIsContainedArray	Array<bool>&		
←	outPoints	Optional<Array<Point2D>&>	NIL	Points that are contained
←	outAreAllContained	Optional<bool&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPoints**, **outAreAllContained**.

Read more about Optional Outputs.

TestPointInBox

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point lies in a box.

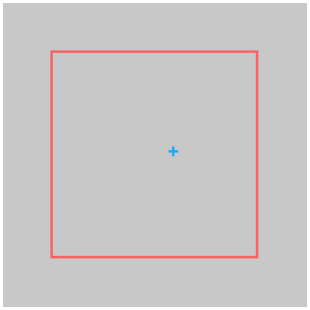
Syntax

```
void avl::TestPointInBox
(
 const avl::Point2D& inPoint,
 const avl::Box& inBox,
 bool& outIsContained
)
```

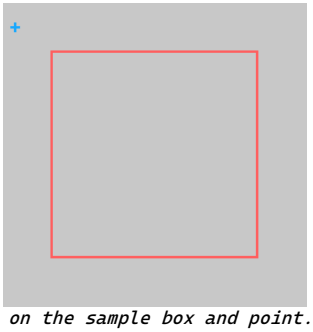
Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inBox	const Box&		
←	outIsContained	bool&		

Examples



TestPointInBox *performed on the sample box and point.* ***outIsContained*** *= True.*



TestPointInBox *performed on the sample box and point.* ***outIsContained*** *= False.*

TestPointInCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point lies inside a circle.

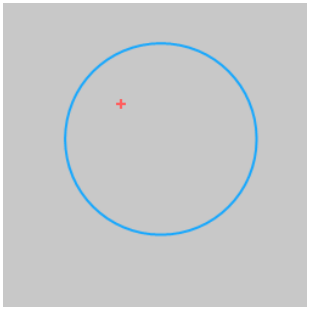
Syntax

```
void avl::TestPointInCircle
(
 const avl::Point2D& inPoint,
 const avl::Circle2D& inCircle,
 bool& outIsContained
)
```

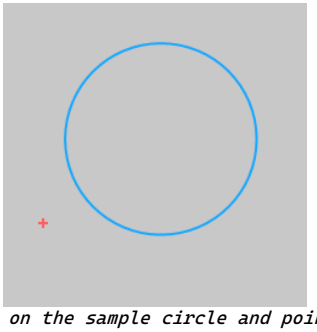
Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inCircle	const Circle2D&		
←	outIsContained	bool&		

Examples



TestPointInCircle *performed on the sample circle and point.* ***outIsContained*** *= True.*



TestPointInCircle *performed on the sample circle and point.* ***outIsContained*** *= False.*

TestPointInRectangle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point lies in a rectangle.

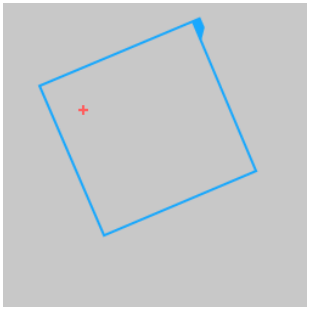
Syntax

```
void avl::TestPointInRectangle
(
 const avl::Point2D& inPoint,
 const avl::Rectangle2D& inRectangle,
 bool& outIsContained
)
```

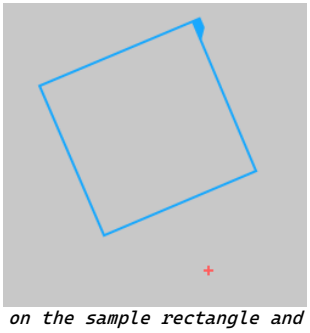
Parameters

	Name	Type	Default	Description
→	inPoint	const Point2D&		
→	inRectangle	const Rectangle2D&		
←	outIsContained	bool&		

Examples



TestPointInRectangle *performed on the sample rectangle and point.* ***outIsContained*** *= True.*



TestPointInRectangle *performed on the sample rectangle and point.* ***outIsContained*** *= False.*

TestSegmentsIntersect

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether two segments intersect.

Syntax

```
void avl::TestSegmentsIntersect
(
 const avl::Segment2D& inSegment1,
 const avl::Segment2D& inSegment2,
 bool& outDoIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inSegment1	const Segment2D&		
→	inSegment2	const Segment2D&		
←	outDoIntersect	bool&

CreateScanMap

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Precomputes a data object that is required for fast 1D edge detection.

Applications: Used together with 1D Edge Detection filters (excluding "_Direct"), but can be moved before the loop if only the scan parameters do not change.

Syntax

```
void avl::CreateScanMap
(
 const avl::ImageFormat& inImageFormat,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 avl::ScanMap& outScanMap,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImageFormat	const ImageFormat&			Dimensions, depth and pixel type of the image on which edge detection will be performed
→	inScanPath	const Path&			Path along which the scan is performed
→	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
→	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
→	inSamplingParams	const SamplingParams&		.interpolation Bilinear	Parameters controlling the sampling process
←	outScanMap	ScanMap&			Optimized data object required for 1D edge detection
←	outAlignedScanPath	Optional<Path&>		NIL	Transformed input path
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributes to a single value of the extracted profile
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**.

Read more about Optional Outputs.

Description

The operation creates a scan map from a given **inScanPath**. The scan map can be later used by other 1D Edge Detection filters.

The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object, typically detected by one of Template Matching filters.

This filter is a part of the 1D Edge Detection toolset. For a comprehensive introduction to this technique please refer to 1D Edge Detection and 1D Edge Detection – Subpixel Precision chapters of our Machine Vision Guide.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

See Also

- ScanSingleEdge – Locates the strongest transition between dark and bright pixels along a given path.
- ScanSingleRidge – Locates the strongest dark or bright pixel peak along a given path.
- ScanSingleStripe – Locates the strongest pair of edges across a given path.

ScanExactlyNEdges

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates a specified number of the strongest transitions between dark and bright pixels along a given path.

Applications: Very fast object detection (or presence verification) when the expected number of edges is clearly defined.

Syntax

```
void avl::ScanExactlyNEdges
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const EdgeScanParams& inEdgeScanParams,
 int inEdgeCount,
 avl::Selection::Type inEdgeSelection,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Conditional<atl::Array<avl::Edge1D> >& outEdges,
 atl::Conditional<atl::Array<avl::Gap1D> >& outGaps,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanMap	const ScanMap&			Data precomputed with CreateScanMap
→	inEdgeScanParams	const EdgeScanParams&		EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f EdgeTransition: BrightToDark)	Parameters controlling the edge extraction process
→	inEdgeCount	int	0 – ∞	1	Number of edges to be found
→	inEdgeSelection	Selection::Type		Selection::Best	Selection mode of the resulting edges
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outEdges	Conditional<Array<Edge1D> >&			Found edges
←	outGaps	Conditional<Array<Gap1D> >&			Gaps between consecutive edges
←	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image using **inScanMap** previously generated from a scan path and finds a set of **inEdgeCount** image edges perpendicular to the path. If no subset (of **inEdgeCount** elements) of detected edges meets the requirements of **inEdgeScanParams.minMagnitude**, **inMinDistance**, **inEdgeScanParams.edgeTransition** then the outputs are set to NIL.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Set **inEdgeCount** to the number of edges that are to be found (the N number).
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If the expected number of edges cannot be found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinDistance** (in pixels) to filter out false edges that appear in proximity to other edges.

Examples

ScanExactlyNEdges *locates the edges using a scan map representing the scan path above (**inEdgeCount** = 61).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the 1D Edge Detection toolset. For a comprehensive introduction to this technique please refer to 1D Edge Detection and 1D Edge Detection – Subpixel Precision chapters of our Machine Vision Guide.

ScanExactlyNRidges

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates a specified number of the strongest dark or bright pixel peak along a given path.

Applications: Very fast detection (or presence verification) of thin structures like wires or scale marks.

Syntax

```
void avl::ScanExactlyNRidges
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const RidgeScanParams& inRidgeScanParams,
 int inRidgeCount,
 avl::Selection::Type inRidgeSelection,

ScanExactlyNStripes

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates a specified number of multiple pairs of opposite edges across a given path.

Applications: Very fast detection (or presence verification) of multiple pairs of opposite edges.

Syntax

```
void avl::ScanExactlyNStripes
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,

 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanMap	const ScanMap&			Data precomputed with CreateScanMap
→	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inStripeCount	int	0 – ∞	1	Number of stripes to be found
→	inStripeSelection	Selection::Type		Selection::Best	Selection mode of the resulting stripes
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive stripes
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive stripes
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outStripes	Conditional<Array<Stripe1D> >&			Found stripes
←	outGaps	Conditional<Array<Gap1D> >&			Distances between consecutive stripes
←	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

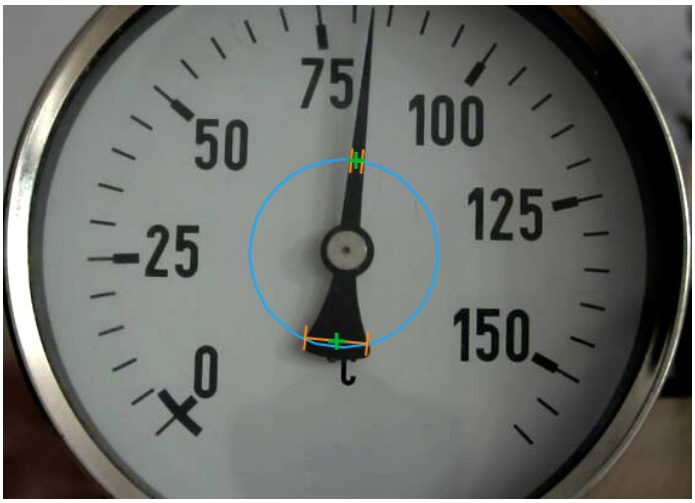
The operation scans the image using **inScanMap** previously generated from a scan path and finds a set of **inStripeCount** consecutive stripes (i.e. pairs of opposite-polarity edges running across the path). If no subset (of **inStripeCount** elements) of detected edge pairs meets the requirements of **inStripeScanParams.stripePolarity**, **inStripeScanParams.minMagnitude**, **inStripeScanParams.minStripeWidth** and **inMinGapWidth** then the outputs are set to NIL.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Set **inStripeCount** to the number of stripes that are to be found (the N number).
- Define **inStripeScanParams.StripePolarity** to detect a particular stripe type, and only that type.
- If the expected number of stripes cannot be found, try decreasing **inStripeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inStripeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinGapWidth** (in pixels) to filter out false stripes that appear in proximity to other stripes.
- Adjust **inStripeScanParams.inMinStripeWidth** and **inStripeScanParams.inMaxStripeWidth** (in pixels) to increase reliability.

Examples



***ScanExactlyNStripes** locates the edge pairs using a scan map representing the scan path above (**inStripeCount** = 2, **inStripeScanParams.stripePolarity** = Dark).*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the 1D Edge Detection toolset. For a comprehensive introduction to this technique please refer to 1D Edge Detection and 1D Edge Detection – Subpixel Precision chapters of our Machine Vision Guide.

ScanExactlyNStripes_Direct

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates a specified number of multiple pairs of opposite edges across a given path (without a scan map).

Applications: Very fast detection (or presence verification) of multiple pairs of opposite edges.

Syntax

```
void avl::ScanExactlyNStripes_Direct
(
 const avl::Image& inImage,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 const avl::StripeScanParams& inStripeScanParams,
 int inStripeCount,
 avl::Selection::Type inStripeSelection,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Conditional<atl::Array<avl::Stripe1D> >& outStripes,
 atl::Conditional<atl::Array<avl::Gap1D> >& outGaps,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Input image
➡	inScanPath	const Path&			Path along which the scan is performed
➡	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
➡	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
➡	inSamplingParams	const SamplingParams&		SamplingParams (Interpolation: Bilinear SamplingStep: 1.0f SampleCount: Nil)	Parameters controlling the sampling process
➡	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
➡	inStripeCount	int	0 – ∞	1	Number of stripes to be found
➡	inStripeSelection	Selection::Type			Selection mode of the resulting stripes
➡	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive stripes
➡	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive stripes
➡	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
⬅	outStripes	Conditional<Array<Stripe1D> >&			Found stripes
⬅	outGaps	Conditional<Array<Gap1D> >&			Distances between consecutive stripes
⬅	outAlignedScanPath	Optional<Path&>		NIL	Transformed input path
⬅	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
⬅	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributes to a single value of the extracted profile
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image along **inScanPath** and finds a set of **inStripeCount** consecutive stripes (i.e. pairs of opposite-polarity edges running across the path). If no subset (of **inStripeCount** elements) of detected edge pairs meets the requirements of **inStripeScanParams.stripePolarity**, **inStripeScanParams.minMagnitude**, **inStripeScanParams.minStripeWidth** and **inMinGapWidth** then the outputs are set to NIL.

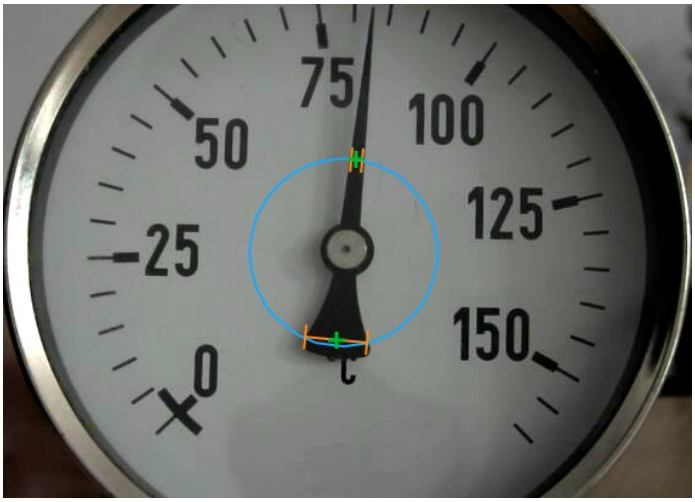
The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object, typically detected by one of Template Matching filters.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Set **inStripeCount** to the number of stripes that are to be found (the N number).
- Define **inStripeScanParams.StripePolarity** to detect a particular stripe type, and only that type.
- If the expected number of stripes cannot be found, try decreasing **inStripeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inStripeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinGapWidth** (in pixels) to filter out false stripes that appear in proximity to other stripes.
- Adjust **inStripeScanParams.inMinStripeWidth** and **inStripeScanParams.inMaxStripeWidth** (in pixels) to increase reliability.

Examples



ScanExactlyNStripes_Direct *locates the edge pairs across* ***inScanPath*** *(****inStripeCount*** *= 2,* ***inStripeScanParams.stripePolarity*** *= Dark).*

Remarks

ScanMultipleEdges

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates multiple transitions between dark and bright pixels along a given path.

Applications: Very fast detection of multiple edge points – usually for object counting or displacement detection.

Syntax

```
void avl::ScanMultipleEdges
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const EdgeScanParams& inEdgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::Edge1D>& outEdges,
 atl::Array<avl::Gap1D>& outGaps,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanMap	const ScanMap&			Data precomputed with CreateScanMap
→	inEdgeScanParams	const EdgeScanParams&		EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f EdgeTransition: BrightToDark)	Parameters controlling the edge extraction process
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outEdges	Array<Edge1D>&			Found edges
←	outGaps	Array<Gap1D>&			Gaps between consecutive edges
←	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image using **inScanMap** previously generated from a scan path and detects image edges perpendicular to the path. Depending on the **inEdgeScanParams.edgeTransition** parameter, edges representing increase or decrease (or both) of image brightness along the path will be taken into account.

When the number of edges to be found is known, one can use the ScanExactlyNEdges.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If too few edges are found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinDistance** (in pixels) to filter out false edges that appear in proximity to other edges.

Examples

ScanExactlyNEdges *locates the edges using a scan map representing the scan path above.*

ScanMultipleStripes

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates multiple pairs of edges across a given path.

Applications: Very fast detection of multiple pairs of opposite edges – usually for counting or width measurements.

Syntax

```
void avl::ScanMultipleStripes
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const StripeScanParams& inStripeScanParams,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::Stripe1D>& outStripes,
 atl::Array<avl::Gap1D>& outGaps,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanMap	const ScanMap&			Data precomputed with CreateScanMap
→	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive stripes
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive stripes

←	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image using **inScanMap** previously generated from a scan path and detects consecutive stripes (i.e. pairs of opposite-polarity edges running across the path). Depending on the **inStripeScanParams.stripePolarity** parameter, dark or bright stripes will be taken into account.

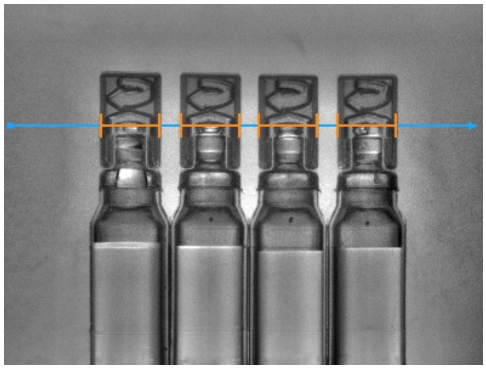
When the number of edge pairs to be measured is known, one can use the ScanExactlyNStripes filter.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Define **inStripeScanParams.StripePolarity** to detect a particular edge type, and only that type.
- If too few stripes are found, try decreasing **inStripeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inStripeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinGapWidth** (in pixels) to filter out false stripes that appear in proximity to other edges.
- Adjust **inStripeScanParams.inMinStripeWidth** and **inStripeScanParams.inMaxStripeWidth** (in pixels) to increase reliability.

Examples



__ScanMultipleStripes__ locates the edge pairs using a scan map representing the scan path above (__inStripeScanParams.stripePolarity__ = Dark, __inStripeScanParams.minStripeWidth__ = 45).

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

This filter is a part of the 1D Edge Detection toolset. For a comprehensive introduction to this technique please refer to 1D Edge Detection and 1D Edge Detection – Subpixel Precision chapters of our Machine Vision Guide.

ScanMultipleStripes_Direct

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates multiple pairs of edges across a given path (without a scan map).

Applications: Very fast detection of multiple pairs of opposite edges – usually for counting or width measurements.

Syntax

```
void avl::ScanMultipleStripes_Direct
(
 const avl::Image& inImage,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 const avl::StripeScanParams& inStripeScanParams,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::Stripe1D>& outStripes,
 atl::Array<avl::Gap1D>& outGaps,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanPath	const Path&			Path along which the scan is performed
→	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
→	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
→	inSamplingParams	const SamplingParams&		SamplingParams (Interpolation: Bilinear SamplingStep: 1.0f SampleCount: Nil)	Parameters controlling the sampling process
→	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive stripes
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive stripes
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outStripes	Array<Stripe1D>&			Found stripes
←	outGaps	Array<Gap1D>&			Distances between consecutive stripes
←	outAlignedScanPath	Optional<Path&>		NIL	Transformed input path
←	outBrightnessProfile	Optional<Profile&>		NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributes to a single value of the extracted profile
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image along **inScanPath** and detects consecutive stripes (i.e. pairs of opposite-polarity edges running across the path). Depending on the **inStripeScanParams.stripePolarity** parameter, dark or bright stripes will be taken into account.

When the number of edge pairs to be measured is known, one can use the ScanExactlyNStripes_Direct filter.

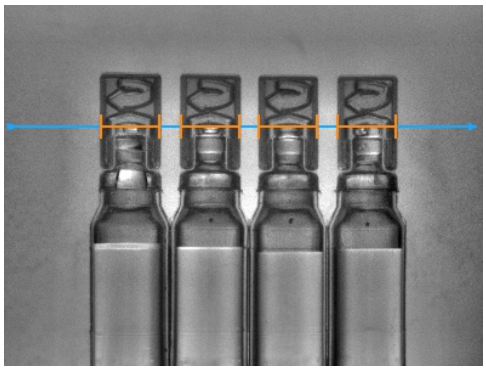
The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object, typically detected by one of Template Matching filters.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

Hints

- Define **inStripeScanParams.StripePolarity** to detect a particular edge type, and only that type.
- If too few stripes are found, try decreasing **inStripeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inStripeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinGapWidth** (in pixels) to filter out false stripes that appear in proximity to other edges.
- Adjust **inStripeScanParams.inMinStripeWidth** and **inStripeScanParams.inMaxStripeWidth** (in pixels) to increase reliability.

Examples



ScanMultipleStripes_Direct *locates the edge pairs across* ***inScanPath*** *(****inStripeScanParams.stripePolarity*** *= Dark,* ***inStripeScanParams.minStripeWidth*** *= 45).*

Remarks

ScanSingleEdge

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates the strongest transition between dark and bright pixels along a given path.

Applications: Very fast detection of an object (e.g. horizontal displacement of a bottle) and simple measurements (e.g. liquid level in a bottle).

Syntax

```
void avl::ScanSingleEdge
(
 const avl::Image& inImage,
 const avl::ScanMap& inScanMap,
 const avl::EdgeScanParams& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Conditional<avl::Edge1D>& outEdge,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inScanMap	const ScanMap&		Data precomputed with CreateScanMap
→	inEdgeScanParams	const EdgeScanParams&	EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f EdgeTransition: BrightToDark)	Parameters controlling the edge extraction process
→	inEdgeSelection	Selection::Type	Selection::Best	Selection mode of the resulting edge
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outEdge	Conditional<Edge1D>&		Found edge
←	outBrightnessProfile	Optional<Profile&>	NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>	NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image using **inScanMap** previously generated from a scan path and locates the strongest edge perpendicular to the path. If the strongest edge is weaker than **inEdgeScanParams.minMagnitude** then the outputs are set to NIL.

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no edge is found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.

Examples

ScanSingleEdge *locates the strongest edge using a scan map representing the scan path above.*

Remarks

ScanSingleEdge_Direct

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates the strongest transition between dark and bright pixels along a given path (without a scan map).

Applications: Very fast detection of an object (e.g. horizontal displacement of a bottle) and simple measurements (e.g. liquid level in a bottle).

Syntax

```
void avl::ScanSingleEdge_Direct
(
 const avl::Image& inImage,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 const avl::EdgeScanParams& inEdgeScanParams,

🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributes to a single value of the extracted profile
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image along **inScanPath** and locates the strongest edge perpendicular to the path. If the strongest edge is weaker than **inEdgeScanParams.minMagnitude** then the outputs are set to NIL.

The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object, typically detected by one of Template Matching filters.

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no edge is found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.

Examples

ScanSingleEdge_Direct *locates the strongest edge across* ***inScanPath****.*

ScanSingleRidge

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates the strongest dark or bright pixel peak along a given path.

Applications: Very fast detection of a thin structure like a wire or a scale mark.

Syntax

```
void avl::ScanSingleRidge
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const RidgeScanParams& inRidgeScanParams,
 avl::Selection::Type inRidgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Conditional<avl::Ridge1D>& outRidge,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inScanMap	const ScanMap&		Data precomputed with CreateScanMap
→	inRidgeScanParams	const RidgeScanParams&	RidgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f RidgeWidth: 5 RidgeMargin: 2 MinMagnitude: 5.0f RidgePolarity: Dark)	Parameters controlling the ridge extraction process
→	inRidgeSelection	Selection::Type	Selection::Best	Selection mode of the resulting ridge
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
←	outRidge	Conditional<Ridge1D>&		Found ridge
←	outBrightnessProfile	Optional<Profile&>	NIL	Extracted image profile
←	outResponseProfile	Optional<Profile&>	NIL	Profile of the ridge operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBrightnessProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the image using **inScanMap** previously generated from a scan path and locates the strongest ridge of the given characteristics. If there is no such ridge then the outputs are set to NIL.

Hints

- Adjust **inRidgeScanParams.RidgeWidth** to the expected thickness of the ridge (in pixels).
- Define **inRidgeScanParams.RidgePolarity** to detect a particular ridge type, and only that type.
- If no ridge is found, try decreasing **inRidgeScanParams.MinMagnitude**.
- For difficult cases try different settings of the **inRidgeScanParams.RidgeOperator** parameter.

Examples

ScanSingleRidge *locates the strongest ridge using a scan map representing the scan path above.*

Remarks

ScanSingleStripe

Header: AVL.h
Namespace: avl
Module: MetrologyBasic

Locates the strongest pair of edges across a given path.

Applications: Very fast detection or measurement of an object defined by a pair of opposite edges.

Syntax

```
void avl::ScanSingleStripe
(
 const avl::Image& inImage,
 const ScanMap& inScanMap,
 const StripeScanParams& inStripeScanParams,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Conditional<avl::Stripe1D>& outStripe,
 atl::Optional<avl::Profile&> outBrightnessProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inScanMap	const ScanMap&		Data precomputed with CreateScanMap
→	inStripeScanParams	const StripeScanParams&	StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Dark MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inStripeSelection	Selection::Type	Selection::Best	Selection mode of the resulting stripe
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outStripe	Conditional<Stripe1D>&		Found stripe

This operation is optimized for AVX2 technology for pixels of type: UINT8.

This operation is optimized for NEON technology for pixels of type: UINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

CreateSurfaceScanMap

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Precomputes a data object that is required for fast 1D edge detection in 3D.

Applications: Used together with 1D Edge Detection 3D filters, but can be moved before the loop if only the scan parameters do not change.

Syntax

```
void avl::CreateSurfaceScanMap
(
 const avl::SurfaceFormat& inSurfaceFormat,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 avl::ScanMap& outScanMap,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurfaceFormat	const SurfaceFormat&			Dimensions, depth image pixel type, coordinate offsets and scales of a surface on which edge detection will be performed
→	inScanPath	const Path&			Path along which the scan is performed
→	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
→	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Desired distance between consecutive sampling points on the scan path; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels of the surface depth image
→	inSurfaceInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of depth image pixel values
←	outScanMap	ScanMap&			Optimized data object required for 1D edge detection in 3D
←	outAlignedScanPath	Optional<Path&>		NIL	Transformed input path
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile; in the image coordinate system
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**.

Read more about Optional Outputs.

Description

The operation creates a scan map from a given **inScanPath**. The scan map can be later used by other 1D Edge Detection 3D filters.

The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object.

Remarks

See Also

- ScanSingleEdge3D – Locates the strongest change of surface height along a given path.

ScanExactlyNEdges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates a specified number of the strongest changes of surface height along a given path.

Syntax

```
void avl::ScanExactlyNEdges3D
(
 const avl::Surface& inSurface,
 const avl::ScanMap& inScanMap,
 const avl::EdgeScanParams3D& inEdgeScanParams,
 int inEdgeCount,
 avl::Selection::Type inEdgeSelection,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Conditional<atl::Array<avl::SurfaceEdge1D> >& outEdges,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inEdgeScanParams	const EdgeScanParams3D&			Parameters controlling the surface edge extraction process
→	inEdgeCount	int	0 – ∞	1	Number of surface edges to be found
→	inEdgeSelection	Selection::Type		Selection::Best	Selection mode of the resulting edges
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outEdges	Conditional<Array<SurfaceEdge1D> >&			Found surface edges
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the surface using **inScanMap** previously generated from a scan path and finds a set of **inEdgeCount** surface edges perpendicular to the path. If no subset (of **inEdgeCount** elements) of detected edges meets the requirements of **inEdgeScanParams.minMagnitude**, **inMinDistance**, **inEdgeScanParams.edgeTransition** then the outputs are set to NIL.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

The operation is very similar to ScanExactlyNEdges from 1D Edge Detection category, but there are some substantial differences. One of these is the possibility of absence of information, because some surface points may not exist at all. To detect such edges, where solely change of existence matters, **Valid/Invalid** options of **inEdgeScanParams.EdgeTransition** can be used. Outside the surface domain (i.e. rectangle defined by input surface width, height, offsets and scales) there are no valid or invalid points, so no edge can be found in the direct vicinity of the domain border.

Because in the **Valid/Invalid** mode all edges have equal strength, if **inEdgeSelection** is set to **Best**, it will be implicitly substituted with **First** selection option.

Please note that when the input surface has unequal scales along X and Y axes and the scan path is not parallel to any of the axes, the results may be slightly less accurate because of uneven sampling along axes.

Hints

- Set **inEdgeCount** to the number of edges that are to be found (the N number).
- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If the expected number of edges cannot be found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinDistance** (in surface coordinates) to filter out false edges that appear in proximity to other edges.

Remarks

ScanExactlyNRidges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates a specified number of the strongest high or low peaks of surface height along a given path.

Syntax

```
void avl::ScanExactlyNRidges3D
(
 const avl::Surface& inSurface,
 const ScanMap& inScanMap,
 const avl::RidgeScanParams3D& inRidgeScanParams,
 int inRidgeCount,

←	outStripes	Conditional<Array<SurfaceStripe1D> >&			Found surface stripes
←	outAlignedScanPath	Optional<Path&>		NIL	Path along which the scan is performed; in the image coordinate system
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile; in the image coordinate system
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

ScanMultipleEdges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates multiple changes of surface height along a given path.

Syntax

```
void avl::ScanMultipleEdges3D
(
 const avl::Surface& inSurface,
 const avl::ScanMap& inScanMap,
 const avl::EdgeScanParams3D& inEdgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Array<avl::SurfaceEdge1D>& outEdges,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inEdgeScanParams	const EdgeScanParams3D&			Parameters controlling the surface edge extraction process
→	inMinDistance	float	0.0 – ∞		Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	NIL	Maximal number of consecutive not existing profile points
←	outEdges	Array<SurfaceEdge1D>&			Found surface edges
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the surface using **inScanMap** previously generated from a scan path and detects surface edges perpendicular to the path. Depending on the **inEdgeScanParams.edgeTransition** parameter, edges representing increase or decrease (or both) of surface height along the path will be taken into account.

When the number of edges to be found is known, one can use the ScanExactlyNEdges3D.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

The operation is very similar to ScanMultipleEdges from 1D Edge Detection category, but there are some substantial differences. One of these is the possibility of absence of information, because some surface points may not exist at all. To detect such edges, where solely change of existence matters, **Valid/Invalid** options of **inEdgeScanParams.EdgeTransition** can be used. Outside the surface domain (i.e. rectangle defined by input surface width, height, offsets and scales) there are no valid or invalid points, so no edge can be found in the direct vicinity of the domain border.

Please note that when the input surface has unequal scales along X and Y axes and the scan path is not parallel to any of the axes, the results may be slightly less accurate because of uneven sampling along axes.

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If too few edges are found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinDistance** (in surface coordinates) to filter out false edges that appear in proximity to other edges.

Remarks

- ScanExactlyNEdges3D – Locates a specified number of the strongest changes of surface height along a given path.
- ScanMultipleEdges3D_Direct – Locates multiple changes of surface height along a given path.

ScanMultipleEdges3D_Direct

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates multiple changes of surface height along a given path.

Syntax

```
void avl::ScanMultipleEdges3D_Direct
(
 const avl::Surface& inSurface,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 const avl::EdgeScanParams3D& inEdgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Array<avl::SurfaceEdge1D>& outEdges,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanPath	const Path&			Path along which the scan is performed
→	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
→	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Distance between consecutive sampling points on the scan path; if Nil, the bigger of surface X and Y scales is chosen
→	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
→	inSurfaceInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
→	inEdgeScanParams	const EdgeScanParams3D&		EdgeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f EdgeTransition: LowToHigh)	Parameters controlling the surface edge extraction process
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outEdges	Array<SurfaceEdge1D>&			Found surface edges
←	outAlignedScanPath	Optional<Path&>		NIL	Path along which the scan is performed; in the image coordinate system
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile; in the image coordinate system
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the surface along **inScanPath** and detects surface edges perpendicular to the path. Depending on the **inEdgeScanParams.edgeTransition** parameter, edges representing increase or decrease (or both) of surface height along the path will be taken into account.

When the number of edges to be found is known, one can use the ScanExactlyNEdges3D_Direct.

The optional parameter **inScanPathAlignment** defines a transform to be performed on the **inScanPath** so that the actual scan path (**outAlignedScanPath**) is adjusted to the position of the object.

Note that in case of a scan path which is closed, the parameters controlling the distances between consecutive found objects do not control the distance between the first and the last of the found objects (counting from the beginning of the scan path).

The operation is very similar to ScanMultipleEdges_Direct from 1D Edge Detection category, but there are some substantial differences. One of these is the possibility of absence of information, because some surface points may not exist at all. To detect such edges, where solely change of existence matters, **Valid/Invalid** options of **inEdgeScanParams.EdgeTransition** can be used. Outside the surface domain (i.e. rectangle defined by input surface width, height, offsets and scales) there are no valid or invalid points, so no edge can be found in the direct vicinity of the domain border.

Please note that when the input surface has unequal scales along X and Y axes and the scan path is not parallel to any of the axes, the results may be slightly less accurate because of uneven sampling along axes.

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If too few edges are found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.
- Adjust **inMinDistance** (in surface coordinates) to filter out false edges that appear in proximity to other edges.

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

ScanMultipleRidges3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates multiple high or low peaks of surface height along a given path.

Syntax

```
void avl::ScanMultipleRidges3D
(
 const avl::Surface& inSurface,
 const ScanMap& inScanMap,
 const avl::RidgeScanParams3D& inRidgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Array<avl::SurfaceRidge1D>& outRidges,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inRidgeScanParams	const RidgeScanParams3D&			Parameters controlling the surface ridge extraction process
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive ridges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive ridges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outRidges	Array<SurfaceRidge1D>&			Found surface ridges
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the ridge operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outHeightProfile**, **outResponseProfile**.

ScanMultipleStripes3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates multiple pairs of changes of surface height along a given path.

Syntax

```
void avl::ScanMultipleStripes3D
(
 const avl::Surface& inSurface,
 const avl::ScanMap& inScanMap,
 const avl::StripeScanParams3D& inStripeScanParams,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Array<avl::SurfaceStripe1D>& outStripes,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inStripeScanParams	const StripeScanParams3D&			Parameters controlling the surface stripe extraction process
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive surface stripes
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive surface stripes
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outStripes	Array<SurfaceStripe1D>&			Found surface stripes
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

ScanSingleEdge3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates the strongest change of surface height along a given path.

Syntax

```
void avl::ScanSingleEdge3D
(
 const avl::Surface& inSurface,
 const avl::ScanMap& inScanMap,
 const avl::EdgeScanParams3D& inEdgeScanParams,
 avl::Selection::Type inEdgeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Conditional<avl::SurfaceEdge1D>& outEdge,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inEdgeScanParams	const EdgeScanParams3D&			Parameters controlling the surface edge extraction process
→	inEdgeSelection	Selection::Type		Selection::Best	Selection mode of the resulting edge
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outEdge	Conditional<SurfaceEdge1D>&			Found surface edge
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

Description

The operation scans the surface using **inScanMap** previously generated from a scan path and locates the strongest edge perpendicular to the path. If the strongest edge is weaker than **inEdgeScanParams.minMagnitude** then the outputs are set to NIL.

The operation is very similar to ScanSingleEdge from 1D Edge Detection category, but there are some substantial differences. One of these is the possibility of absence of information, because some surface points may not exist at all. To detect such edges, where solely change of existence matters, **Valid/Invalid** options of **inEdgeScanParams.EdgeTransition** can be used. Outside the surface domain (i.e. rectangle defined by input surface width, height, offsets and scales) there are no valid or invalid points, so no edge can be found in the direct vicinity of the domain border.

Because in the **Valid/Invalid** mode all edges have equal strength, if **inEdgeSelection** is set to **Best**, it will be implicitly substituted with **First** selection option.

Please note that when the input surface has unequal scales along X and Y axes and the scan path is not parallel to any of the axes, the results may be slightly less accurate because of uneven sampling along axes.

Hints

- Define **inEdgeScanParams.EdgeTransition** to detect a particular edge type, and only that type.
- If no edge is found, try decreasing **inEdgeScanParams.MinMagnitude**. Verify this with the values on the **outResponseProfile** output.
- If consecutive edges are closer than 6 pixels apart, change **inEdgeScanParams.ProfileInterpolation** to **Quadratic3**.

Remarks

ScanSingleStripe3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates the strongest pair of changes of surface height along a given path.

Syntax

```
void avl::ScanSingleStripe3D
(
 const avl::Surface& inSurface,
 const avl::ScanMap& inScanMap,
 const avl::StripeScanParams3D& inStripeScanParams,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Conditional<avl::SurfaceStripe1D>& outStripe,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inScanMap	const ScanMap&			Data precomputed with CreateSurfaceScanMap
→	inStripeScanParams	const StripeScanParams3D&			Parameters controlling the surface stripe extraction process
→	inStripeSelection	Selection::Type		Selection::Best	Selection mode of the resulting stripe
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
→	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
←	outStripe	Conditional<SurfaceStripe1D>&			Found surface stripe
←	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

ScanSingleStripe3D_Direct

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Locates the strongest pair of changes of surface height along a given path.

Syntax

```
void avl::ScanSingleStripe3D_Direct
(
 const avl::Surface& inSurface,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 const avl::StripeScanParams3D& inStripeScanParams,
 avl::Selection::Type inStripeSelection,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Optional<int> inMaxProfileGapWidth,
 atl::Conditional<avl::SurfaceStripe1D>& outStripe,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Optional<avl::Profile&> outHeightProfile = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			Input surface
➡	inScanPath	const Path&			Path along which the scan is performed
➡	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
➡	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Distance between consecutive sampling points on the scan path; if Nil, the bigger of surface X and Y scales is chosen
➡	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
➡	inSurfaceInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
➡	inStripeScanParams	const StripeScanParams3D&		StripeScanParams3D (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Low MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the surface stripe extraction process
➡	inStripeSelection	Selection::Type			Selection mode of the resulting surface stripe
➡	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
➡	inMaxProfileGapWidth	Optional<int>	0 – ∞	1	Maximal number of consecutive not existing profile points
⬅	outStripe	Conditional<SurfaceStripe1D>&			Found surface stripe
⬅	outAlignedScanPath	Optional<Path&>		NIL	Path along which the scan is performed; in the image coordinate system
⬅	outHeightProfile	Optional<Profile&>		NIL	Extracted surface height profile
⬅	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response
🔍	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile; in the image coordinate system
🔍	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**, **outHeightProfile**, **outResponseProfile**.

Read more about Optional Outputs.

81. Histogram Spatial Transforms

Table of content:

- CropHistogram

CropHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Confines a histogram to its continuous segment.

Syntax

```
void avl::CropHistogram
(
 const avl::Histogram& inHistogram,
 const int inStart,
 const int inBinCount,
 avl::Histogram& outHistogram
)
```

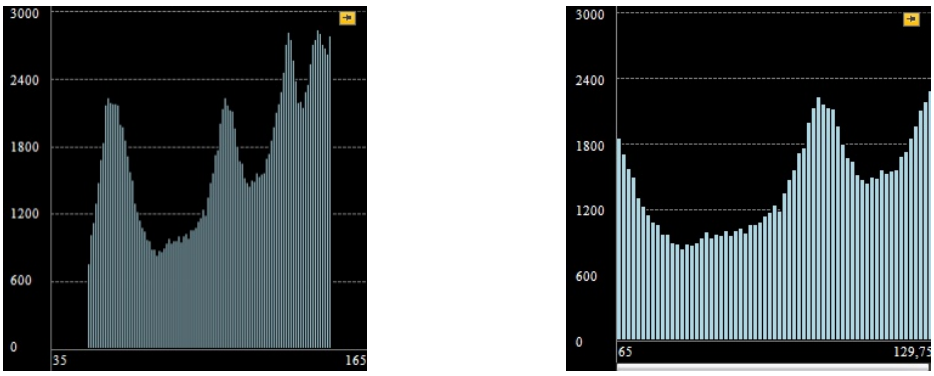
Parameters

	Name	Type	Range	Default	Description
→	inHistogram	const Histogram&			Input histogram
→	inStart	const int	0 – ∞		Index of the first element of the input histogram that will be included in the output histogram
→	inBinCount	const int	0 – ∞		Number of bins in the output histogram
←	outHistogram	Histogram&			Output histogram

Description

Operation crops histogram to bins which are enclosed in **inBinCount** bins beginning from **inStart** bin.

Examples



CropHistogram *performed on the sample histogram with* ***inStart*** *= 15,* ***inBinCount*** *= 65.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Selected index range exceeds the input histogram in CropHistogram.

See Also

- DivideHistogram – Divides each bin value by a number.
- MultiplyHistogram – Multiplies each bin value by a number.
- SubtractFromHistogram – Decreases each bin value by a number.

82. Profile Spatial Transforms

Table of content:

- CropProfile
- ResizeProfile
- RotateProfile
- ShrinkProfileNTimes
- UncropProfile

CropProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Confines a profile to its continuous subsequence.

Syntax

```
void avl::CropProfile
(
 const avl::Profile& inProfile,
 const int inStart,
 atl::Optional<const int&> inLength,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inStart	const int	0 – ∞		Index of the first element of the input profile that will be included in the output profile
→	inLength	Optional<const int&>	0 – ∞	NIL	Length of the output profile
←	outProfile	Profile&			Output profile

Description

The operation crops profile to a new size. It removes values from **inProfile**, except those, which are included between **inStart** and **inStart** + **inLength** indexes.

Remarks

Value of **inLength** set to Auto means that the operation is performed on all elements starting from **inStart** till the end of **inProfile**.

Errors

List of possible exceptions:

Error type	Description
DomainError	Selected index range exceeds the input profile in CropProfile.

See Also

- BlendImages – Computes weighted sum pixel by pixel.
- LerpImages – Interpolates two images linearly pixel by pixel.

ResizeProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Changes the size of a profile, preserving its shape.

Syntax

```
void avl::ResizeProfile
(
 const avl::Profile& inProfile,
 const int inNewSize,
 avl::ResizeProfileInterpolation::Type inInterpolation,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inNewSize	const int	1 – ∞	1	
→	inInterpolation	ResizeProfileInterpolation::Type			
←	outProfile	Profile&			Output profile

RotateProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Moves the last element ahead of the first one (inShift times).

Syntax

```
void avl::RotateProfile
(
 const avl::Profile& inProfile,
 const int inShift,
 avl::Profile& outProfile
)
```

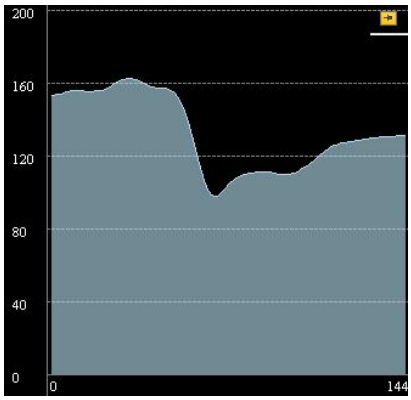
Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inShift	const int	0	
←	outProfile	Profile&		Output profile

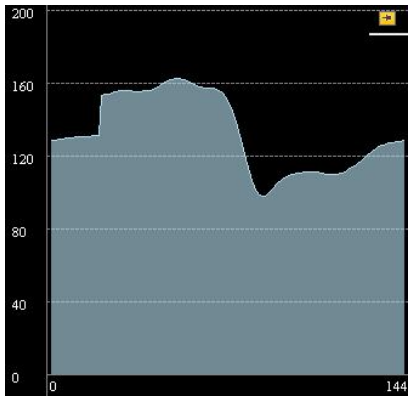
Description

Operation computes the profile of input profile elements shifted cyclically.

Examples

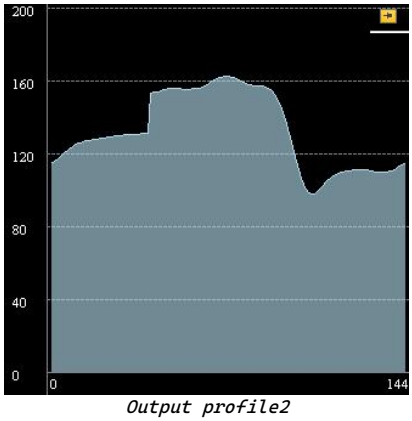


Input profile

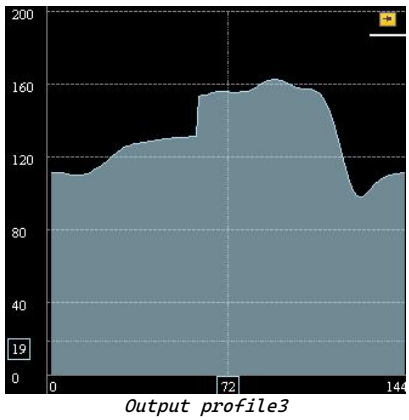


Output profile1

RotateProfile** performed on input profile with **inShift** = 20 produced **outProfile** = **Output profile1



Output profile2



Output profile3

RotateProfile** performed on input profile with **inShift** = 40 produced **outProfile** = **Output profile2** and operation performed on the same input profile with **inShift** = 60 produced **outProfile** = **Output profile3

ShrinkProfileNTimes

Header: AVL.h
Namespace: avl
Module: FoundationPro

Reduces the length of a profile N-times by averaging each N consecutive elements.

Syntax

```
void avl::ShrinkProfileNTimes
(
 const avl::Profile& inProfile,
 const int inN,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inN	const int	1 – ∞	2	The scaling coefficient
←	outProfile	Profile&			Output profile

UncropProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Extends the profile by adding zeros at the beginning and at the end.

Applications: Undoes CropProfile.

Syntax

```
void avl::UncropProfile
(
 const avl::Profile& inProfile,
 int inStart,
 int inLength,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inStart	int	0 – ∞		Same as in CropProfile
→	inLength	int	0 – ∞		Length of the output profile
←	outProfile	Profile&			Output profile

83. Image Pixel Statistics

Table of content:

- DaPImageMedian
- ImageAverage
- ImageAverageHSx
- ImageMaximum
- ImageMinimum
- ImageStatistics
- ImageSum

DaPImageMedian

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the average direction within the region of interest.

Syntax

```
void avl::DaPImageMedian
(
 const avl::Image& inDaPImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::AngleRange::Type inAngleRange,
 float& outMedianAngle
)
```

Parameters

	Name	Type	Default	Description
→	inDaPImage	const Image&		A result of GradientDirAndPresenceImage filter
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inAngleRange	AngleRange::Type	_0_360	
←	outMedianAngle	float&		

Requirements

For input **inDaPImage** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inDaPImage pixel format in DaPImageMedian. Supported formats: 1xUInt8.

Also in **AVL Lite**

ImageAverage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of the image pixel values.

Syntax

```
void avl::ImageAverage
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Pixel& outAverageColor,
 atl::Optional<float&> outAverageValue = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outAverageColor	Pixel&		Average of each channel
←	outAverageValue	Optional<float&>	NIL	Average of the entire image

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAverageValue**.

Read more about Optional Outputs.

Description

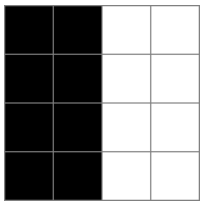
The function calculates average of pixel values in the **inImage**.

Average values of pixels calculated for each channel are returned in **outAverageColor**, while calculated for the region of interest - in **outAverageValue**. If region of interest isn't specified, average is calculated for the entire image.

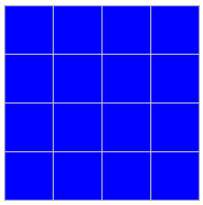
Hints

- Connect **inImage** with the output of your image acquisition filter.

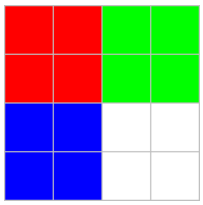
Examples



In this single-channel image, average will be 127.5 for the channel and for the entire image (if the region of interested isn't specified).



In this three-channel RGB image, average will be 0 for R and G channels and 255 for the B channel. If we don't specify the region of interest, average of the image will be 85.0 (because arithmetic mean of 0, 0, and 255 is 85.0).



In this three-channel RGB image, average will be 63.75 for R and B channels and 127.5 for the G channel. If we don't specify the region of interest, average of the image will be 85.0 (because arithmetic mean of 63.75, 63.75 and 127.5 is 85.0).

Remarks

Minimal image size requirement

The input image shouldn't be empty.

Minimal region of interest size requirement

The input region of interest shouldn't be empty.

Hardware Acceleration

This operation is optimized for SSSE41 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty image on input in ImageAverage.
DomainError	Empty region of interest on input in ImageAverage.
DomainError	Region exceeds an input image in ImageAverage.

See Also

- ImageAverageHSx - Computes the average of the HSV, HSL or HSI image pixel values.
- ImageMaximum - Finds the location and the value of the brightest pixel.
- ImageMinimum - Finds the location and the value of the darkest pixel.
- ImageSum - Computes the sum of the image pixel values.

ImageAverageHSx

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of the HSV, HSL or HSI image pixel values.

Syntax

```
void avl::ImageAverageHSx
(
 const avl::Image& inRgbImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::HSxColorModel::Type inColorModel,
 atl::Optional<int> inMinSaturation,
 int& outHAverage,
 int& outSAverage,
 int& outBAverage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRgbImage	const Image&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inColorModel	HSxColorModel::Type			Selected color model
→	inMinSaturation	Optional<int>	0 – 255	0	
←	outHAverage	int&			Output hue average
←	outSAverage	int&			Output saturation average
←	outBAverage	int&			Output brightness average

Requirements

For input **inRgbImage** only pixel formats are supported: 3×uint8.

Read more about pixel formats in Image documentation.

Description

The filter finds average values of the HSV, HSL or HSI color space image from the RGB image **inRgbImage** within specific region **inRoi**.

The calculations take into account only these pixels which have saturation a greater than **inMinSaturation**.

Filter returns average values of a hue, saturation and brightness.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageAverageHSx.
DomainError	Not supported inRgbImage pixel format in ImageAverageHSx. Supported formats: 3xUInt8.

ImageMaximum

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Finds the location and the value of the brightest pixel.

Syntax

```
void avl::ImageMaximum
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Location&> outMaximumLocation,
 atl::Optional<float&> outMaximumValue = atl::NIL
)
```

Parameters

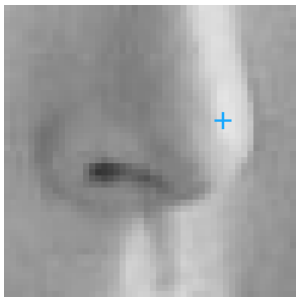
	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outMaximumLocation	Optional<Location&>		
←	outMaximumValue	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMaximumLocation**, **outMaximumValue**.

Read more about Optional Outputs.

Examples



ImageMaximum *used to detect the brightest point.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in ImageMaximum.
DomainError	Region exceeds an input image in ImageMaximum.

ImageMinimum

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Finds the location and the value of the darkest pixel.

Syntax

```
void avl::ImageMinimum
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Location&> outMinimumLocation,
 atl::Optional<float&> outMinimumValue = atl::NIL
)
```

Parameters

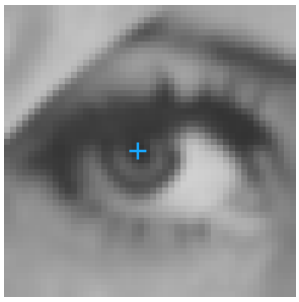
	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outMinimumLocation	Optional<Location&>		
←	outMinimumValue	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinimumLocation**, **outMinimumValue**.

Read more about Optional Outputs.

Examples



ImageMinimum *used to detect the darkest point.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in ImageMinimum.
DomainError	Region exceeds an input image in ImageMinimum.

ImageStatistics

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes various statistics of the image pixel values.

Syntax

```
void avl::ImageStatistics
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Optional<avl::Location&> outMinimumLocation = atl::NIL,
 atl::Optional<float&> outMinimumValue = atl::NIL,
 atl::Optional<avl::Location&> outMaximumLocation = atl::NIL,
 atl::Optional<float&> outMaximumValue = atl::NIL,
 atl::Optional<avl::Pixel&> outAverageColor = atl::NIL,
 atl::Optional<float&> outAverageValue = atl::NIL,
 atl::Optional<avl::Pixel&> outSumColor = atl::NIL,
 atl::Optional<float&> outSumValue = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outMinimumLocation	Optional<Location&>	NIL	
←	outMinimumValue	Optional<float&>	NIL	
←	outMaximumLocation	Optional<Location&>	NIL	
←	outMaximumValue	Optional<float&>	NIL	
←	outAverageColor	Optional<Pixel&>	NIL	
←	outAverageValue	Optional<float&>	NIL	
←	outSumColor	Optional<Pixel&>	NIL	
←	outSumValue	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinimumLocation**, **outMinimumValue**, **outMaximumLocation**, **outMaximumValue**, **outAverageColor**, **outAverageValue**, **outSumColor**, **outSumValue**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for SSSE41 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageStatistics.

ImageSum

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the sum of the image pixel values.

Syntax

```
void avl::ImageSum
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Pixel& outSumColor,
 atl::Optional<float&> outSumValue = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outSumColor	Pixel&		
←	outSumValue	Optional<float&>	NIL	

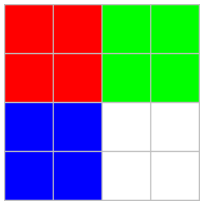
Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSumValue**.

Read more about Optional Outputs.

Examples

Assume, that the subject of the analysis is 4x4 image made of pixels in different colors – red, green, blue and white:



Red (255, 0, 0)

Green (0, 255, 0)

Blue (0, 0, 255)

White (255, 255, 255)

On the output **outSumColor** the sum of pixel values for each channel of an image will be computed.
For above example it will be R, G and B components, but it is also possible to use another color spaces.
Sum of color for R channel will be: $4*255+4*255=2040$ – sum of four red pixels and four red-components from white pixels.
Similarly, sum of colors for G channel and B channel will also be: $4*255+4*255=2040$
Finally, the result for above example will be 1x4 dimensional vector [2040, 2040, 2040, 0]. Notice, that zero is present in result vector, because RGB color space has only three components.

On the output **outSumValue** the average value of pixel of the image will be calculated according to the following formula:

Sum of elements of **outSumColor** / number of components in color space

Therefore, he result for above example will be $\frac{2040+2040+2040}{3}=\frac{6120}{3}=2040$

Remarks

When only a part of an image should be processed use **inRoi** input to specify region of interest.

Hardware Acceleration

This operation is optimized for SSSE41 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for AVX2 technology for pixels of types: 1xUINT8, 3xUINT8.

This operation is optimized for NEON technology for pixels of types: 1xUINT8, 3xUINT8.

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageSum.

84. Barcodes

Table of content:

- DecodeBarcode
- DecodeBarcodeEx
- ReadMultipleBarcodes
- ReadSingleBarcode
- RecognizeBarcode

DecodeBarcode

Header: AVL.h
Namespace: avl
Module: Barcodes

Translates an array of bar widths to sequence of digits or text in accordance to the selected barcode standard.

Applications: Decoding of barcodes whose bars have been measured in a non-standard way.

Syntax

```
void avl::DecodeBarcode
(
 const atl::Array<float>& inBarWidths,
 atl::Optional<avl::BarcodeFormat::Type> inBarcodeFormat,
 atl::Conditional<atl::String>& outDecodedText,
 atl::Conditional<avl::BarcodeFormat::Type>& outBarcodeFormat,
 atl::Conditional<float>& outPpm = atl::Dummy<atl::Conditional<float>>(),
 atl::Conditional<int>& outStart = atl::Dummy<atl::Conditional<int>>(),
 atl::Conditional<int>& outCount = atl::Dummy<atl::Conditional<int>>()
)
```

Parameters

	Name	Type	Default	Description
→	inBarWidths	const Array<float>&		Widths of the barcode bars (starting with width of the black bar)
→	inBarcodeFormat	Optional<BarcodeFormat::Type>	EAN13	Format of the barcode
←	outDecodedText	Conditional<String>&		Decoded barcode text or nothing if decoding failed
←	outBarcodeFormat	Conditional<BarcodeFormat::Type>&		Decoded barcode format or nothing if decoding failed
←	outPpm	Conditional<float>&	Dummy<Conditional<float>>()	
←	outStart	Conditional<int>&	Dummy<Conditional<int>>()	
←	outCount	Conditional<int>&	Dummy<Conditional<int>>()	

Description

This filter is especially useful when a barcode is not provided in a standard black and white printed form.

Use this filter to decode a barcode printed or engraved on circular or distorted surfaces. Also the filter can be used to decode a barcode when one of colors is transparent due to printing on glass or other transparent surface.

It can be useful in decoding damaged codes in which barcode position detection is very complex.

Use the ScanMultipleStripes filter to get the bar widths.

Hints

- Pass an array of computed widths of consecutive black and white bars to the **inBarWidths** input.
- Select **inBarcodeFormat** according to the type of codes you want to read. If you choose the wrong format, the codes will not be recognized. The Auto value causes decoding of UPC-A codes as EAN-13 codes.

Remarks

Minimal bar width requirement

To provide precise detection of the barcode width of the thinnest bar should be at least **1.5** pixels.

Depending on the barcode format guard or start/end code patterns must be readable.

Using a relative coordinate systems

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

See Also

- ReadSingleBarcode – Reads a single barcode (1D) in the input image.
- ReadMultipleBarcodes – Reads multiple barcodes (1D) in the input image.
- RecognizeBarcode – Extracts information from a barcode located in the input image at a given position.

DecodeBarcodeEx

Header: AVL.h
Namespace: avl

Translates an array of bar widths to sequence of digits or text in accordance to the selected barcode standard.

Applications: Decoding of barcodes whose bars have been measured in a non-standard way.

Syntax

```
void avl::DecodeBarcodeEx
(
 const atl::Array<float>& inBarWidths,
 const atl::Array<float>& inEdgeMagnitudes,
 atl::Optional<avl::BarcodeFormat::Type> inBarcodeFormat,
 atl::Optional<int> inDecoderVersion,
 atl::Optional<bool> inEliminateExcessiveEdges,
 atl::Conditional<atl::String>& outDecodedText,
 atl::Conditional<avl::BarcodeFormat::Type>& outBarcodeFormat,
 atl::Conditional<float>& outPpm,
 atl::Conditional<int>& outStart,
 atl::Conditional<int>& outCount,
 bool& outIsUncertain,
 atl::Optional<atl::Array<float>&> outSymbolGrades = atl::NIL,
 atl::Optional<bool&> outStopSymbolFound = atl::NIL,
 atl::Optional<atl::Array<int>&> outDecodedSymbols = atl::NIL,
 atl::Optional<bool&> outStartSymbolFound = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inBarWidths	const Array<float>&			Widths of the barcode bars (starting with width of the black bar)
→	inEdgeMagnitudes	const Array<float>&			Strengths of the edges between the bars (starting with the edge before the first black bar)
→	inBarcodeFormat	Optional<BarcodeFormat::Type>		NIL	Format of the barcode
→	inDecoderVersion	Optional<int>	0 – 10	NIL	To test quickly other versions
→	inEliminateExcessiveEdges	Optional<bool>		NIL	Whether to try suppressing weaker edges or not
←	outDecodedText	Conditional<String>&			Decoded barcode text or nothing if decoding failed
←	outBarcodeFormat	Conditional<BarcodeFormat::Type>&			Decoded barcode format or nothing if decoding failed
←	outPpm	Conditional<float>&			Average number of pixels per module
←	outStart	Conditional<int>&			Start index of the barcode in the input array
←	outCount	Conditional<int>&			Actual number of bars used for decoding
←	outIsUncertain	bool&			Flag indicating whether the decoder was trying harder to read it
←	outSymbolGrades	Optional<Array<float>&>		NIL	
←	outStopSymbolFound	Optional<bool&>		NIL	
←	outDecodedSymbols	Optional<Array<int>&>		NIL	
←	outStartSymbolFound	Optional<bool&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outSymbolGrades**, **outStopSymbolFound**, **outDecodedSymbols**, **outStartSymbolFound**.

Read more about Optional Outputs.

ReadMultipleBarcodes

Header: AVL.h
Namespace: avl
Module: Barcodes

Reads multiple barcodes (1D) in the input image.

Applications: For basic linear barcode reading applications.

Syntax

```
void avl::ReadMultipleBarcodes
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::BarcodeParams& inBarcodeParams,
 const avl::BarcodeDecodingParams& inDecodingParams,
 int inMaxBarcodeCount,
 atl::Array<avl::Barcode>& outBarcodes,
 atl::Optional<atl::Array<avl::Rectangle2D>&> outBarcodeCandidates = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedRoi = atl::NIL,
 avl::Image& diagGradientImage,
 atl::Array<atl::Array<avl::Segment2D>>& diagScheduledScanSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const ShapeRegion&>		NIL	Region of interest
→	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the region of interest to the position of the inspected object
→	inBarcodeParams	const BarcodeParams&			Specification of barcodes that can be detected
→	inDecodingParams	const BarcodeDecodingParams&			Parameters of the barcode decoding algorithm
→	inMaxBarcodeCount	int	1 – ∞	2	Maximum number of barcodes in one image
←	outBarcodes	Array<Barcode>&			List of barcodes that have been correctly detected and decoded
←	outBarcodeCandidates	Optional<Array<Rectangle2D>&>		NIL	Places with high gradient values that are further investigated
←	outAlignedRoi	Optional<ShapeRegion&>		NIL	Input ROI after transformation (in the image coordinates)
🔍	diagGradientImage	Image&			Image of gradient directions
🔍	diagScheduledScanSegments	Array<Array<Segment2D>>&			Scheduled scan segments

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBarcodeCandidates**, **outAlignedRoi**.

Read more about Optional Outputs.

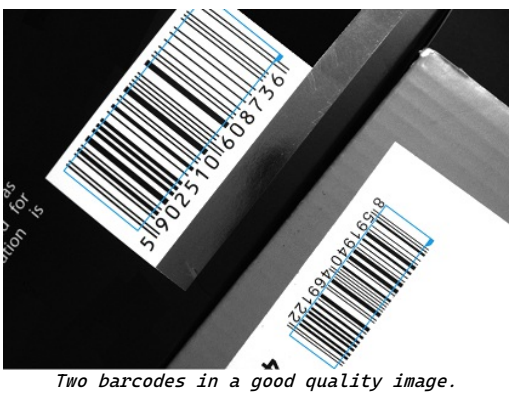
Description

This filter detects barcodes present in the input image and reads their content.

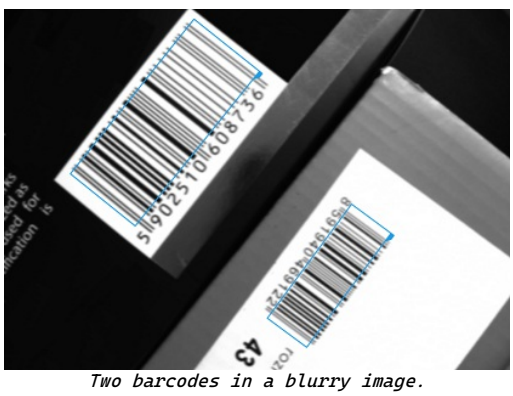
Hints

- Connect **inImage** with the output of your image acquisition filter.
- Select **inBarcodeParams.Format** according to the type of codes you want to read. If you choose the wrong format, the codes will not be recognized. Setting its value to Auto can increase the computation time considerably. Furthermore, the Auto value causes detection of UPC-A codes as EAN-13 codes.
- If the image resolution is high, set **inBarcodeParams.MaxModuleSize** accordingly or resize/downsample the input image.

Examples



Two barcodes in a good quality image.



Two barcodes in a blurry image.

Remarks

Minimal bar width requirement

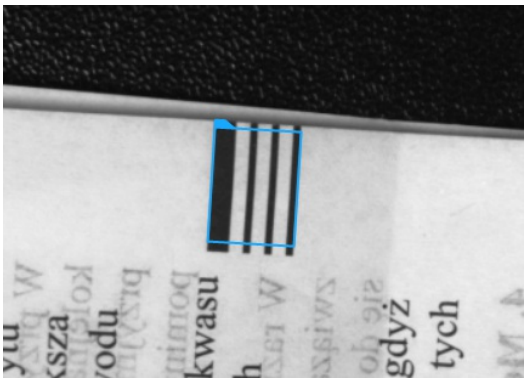
To provide precise detection of the barcode width of the thinnest bar should be at least **1.5** pixels.

Depending on the barcode format guard or start/end code patterns must be readable.

Pharmacode usage

The pharmacode barcode type can be read correctly in both directions. To get results from both directions use a **Pharmacode** and **PharmacodeInversed** barcode types.

Before decoding a Pharmacode the code orientation angle is normalized to a range from -45° to 135° what makes the code decoding more stable



Results of reading using a different Pharmacode directions: ***Pharmacode*** *= 23 and* ***PharmacodeInversed*** *= 16.*

Using a relative coordinate systems

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- ReadSingleBarcode – Reads a single barcode (1D) in the input image.
- DecodeBarcode – Translates an array of bar widths to sequence of digits or text in accordance to the selected barcode standard.
- RecognizeBarcode – Extracts information from a barcode located in the input image at a given position.

ReadSingleBarcode

Header: AVL.h
Namespace: avl
Module: Barcodes

Reads a single barcode (1D) in the input image.

Applications: For basic linear barcode reading applications.

Syntax

```
void avl::ReadSingleBarcode
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::BarcodeParams& inBarcodeParams,
 const avl::BarcodeDecodingParams& inDecodingParams,
 atl::Conditional<avl::Barcode>& outBarcode,
 atl::Optional<atl::Array<avl::Rectangle2D>&> outBarcodeCandidates = atl::NIL,
 atl::Optional<avl::ShapeRegion&> outAlignedRoi = atl::NIL,
 avl::Image& diagGradientImage,
 atl::Array<atl::Array<avl::Segment2D>>& diagScheduledScanSegments
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const ShapeRegion&>	NIL	Region of interest
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the region of interest to the position of the inspected object
→	inBarcodeParams	const BarcodeParams&		Specification of barcode that can be detected
→	inDecodingParams	const BarcodeDecodingParams&		Parameters of the barcode decoding algorithm
←	outBarcode	Conditional<Barcode>&		A barcode that has been correctly detected and decoded
←	outBarcodeCandidates	Optional<Array<Rectangle2D>&>	NIL	Places with high gradient values that are further investigated
←	outAlignedRoi	Optional<ShapeRegion&>	NIL	Input ROI after transformation (in the image coordinates)
🔍	diagGradientImage	Image&		Image of gradient directions
🔍	diagScheduledScanSegments	Array<Array<Segment2D>>&		Scheduled scan segments

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outBarcodeCandidates**, **outAlignedRoi**.

RecognizeBarcode

Header: AVL.h
Namespace: avl
Module: Barcodes

Extracts information from a barcode located in the input image at a given position.

Applications: Most often used after a barcode detection filter.

Syntax

```
void avl::RecognizeBarcode
(
 const avl::Image& inImage,
 const avl::Rectangle2D& inBarcodePosition,
 atl::Optional<const avl::CoordinateSystem2D&> inBarcodePositionAlignment,
 const avl::BarcodeParams& inBarcodeParams,

 const int inScanWidth,
 const float inMinEdgeStrength,
 atl::Conditional<avl::Barcode>& outBarcode,
 atl::Optional<avl::Rectangle2D&> outAlignedBarcodePosition = atl::NIL,
 atl::Array<avl::Segment2D>& diagScheduledScanSegments
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inBarcodePosition	const Rectangle2D&			Position of the input image in which the barcode is located
→	inBarcodePositionAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the barcode rectangle to the position of the inspected object
→	inBarcodeParams	const BarcodeParams&			Specification of barcode that can be read
→	inScanCount	const int	1 – ∞	5	Number of parallel scans run until first successful read
→	inScanWidth	const int	1 – ∞	5	Width of the single scan
→	inMinEdgeStrength	const float	0.0 – ∞	5.0f	Minimal strength of an extracted edge
←	outBarcode	Conditional<Barcode>&			Decoded barcode or nothing if all of the scans failed
←	outAlignedBarcodePosition	Optional<Rectangle2D&>		NIL	
🔍	diagScheduledScanSegments	Array<Segment2D>&			Scheduled scan segments

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedBarcodePosition**.

DetectEdges

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Extracts a binary image of pixel-precise continuous edges.

Applications: Consistent detection of pixels that belong to contours of variable or unpredictable shape, e.g. screw thread outline or a custom piece of textile.

Syntax

```
void avl::DetectEdges
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::EdgeFilter::Type inEdgeFilter,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 float inMaxJoiningDistance,
 const int inMinBlobArea,
 avl::Image& outEdgesImage,
 avl::Image& diagGradientMagnitudeImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which edges will be extracted
→	inRoi	Optional<const Region&>		NIL	Region of the image from which edges will be extracted
→	inEdgeFilter	EdgeFilter::Type			Type of edge filter used for computing gradients
→	inStdDevX	float	0.0 – ∞	2.0f	Amount of horizontal smoothing used by the edge filter
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Amount of vertical smoothing used by the edge filter (Auto = inStdDevX)
→	inEdgeThreshold	float	0.0 – ∞	15.0f	Sufficient edge strength; edges of that strength will always be detected
→	inEdgeHysteresis	float	0.0 – ∞	5.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxJoiningDistance	float	0.0 – ∞	0.0f	Maximal distance between edges that can be joined
→	inMinBlobArea	const int	0 – ∞	1	Minimal area of an edge blob
←	outEdgesImage	Image&			Image of found edges
🔍	diagGradientMagnitudeImage	Image&			Visualization of the gradient magnitude

In-place Processing

This function supports in-place data processing – you can pass the same reference to **inImage** and **outEdgesImage**

Read more about In-place Computation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

DetectEdges_AsPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Extracts subpixel-precise paths that represent continuous edges.

Applications: Consistent detection of contours of variable or unpredictable shape, e.g. screw thread outline or a custom piece of textile.

Syntax

```
void avl::DetectEdges_AsPaths
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::EdgeFilter::Type inEdgeFilter,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 atl::Optional<float> inMaxJoiningDistance,
 float inMaxJoiningAngle,
 float inJoiningDistanceBalance,
 atl::Optional<float> inJoiningEndingLength,
 float inMinEdgeLength,
 atl::Array<avl::Path>& outEdges,
 avl::Image& diagGradientMagnitudeImage,
 avl::Region& diagEdgeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which edges will be extracted
→	inRoi	Optional<const Region&>		NIL	Region of the image from which edges will be extracted
→	inEdgeFilter	EdgeFilter::Type			Type of edge filter used for computing gradients
→	inStdDevX	float	0.0 – ∞	2.0f	Amount of horizontal smoothing used by the edge filter
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Amount of vertical smoothing used by the edge filter (Auto = inStdDevX)
→	inEdgeThreshold	float	0.0 – ∞	15.0f	Sufficient edge strength; edges of that strength will always be detected
→	inEdgeHysteresis	float	0.0 – ∞	5.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxJoiningDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between edges that can be joined
→	inMaxJoiningAngle	float	0.0 – 180.0	30.0f	Maximal allowed angle between edges being joined
→	inJoiningDistanceBalance	float	0.0 – 1.0	0.0f	Determines how important distance between edges is according to their angle difference
→	inJoiningEndingLength	Optional<float>	1.0 – ∞	NIL	Determines the length of the edge end used for edge angle computing
→	inMinEdgeLength	float	0.0 – ∞	0.0f	Minimal length of an edge
←	outEdges	Array<Path>&			Paths representing found edges
🔍	diagGradientMagnitudeImage	Image&			Visualization of the gradient magnitude
🔍	diagEdgeRegion	Region&			Region representing found edges

Description

The operation extracts edges from the **inRoi** region in the **inImage** image and stores the result in the array of paths **outEdges**. The extraction process is the same as in DetectEdges_AsRegion, the only difference being the data type of the result. This filter returns an array of subpixel-precise paths rather than region computed by DetectEdges_AsRegion.

The extraction process starts from gradient computing. Depending on which edge filter is chosen, gradients are computed using recursive (Deriche or Lanser) or standard non-recursive filter proposed by Canny. The **inStdDevX** and **inStdDevY** parameters control size of the filter mask. The greater their values are, the larger this size is. It should be noted that the execution time of the non-recursive filter depends greatly on the size of the filter mask, while the recursive filters execution time is independent of it.

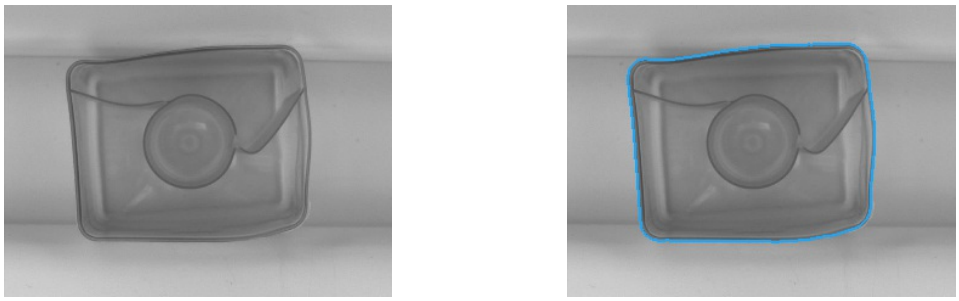
On the so computed gradient image threshold with hysteresis (as in ThresholdImage_Hysteresis) is performed with **inEdgeThreshold** and **inEdgeHysteresis** parameters. After this step only gradients which are strong enough are present. The resulting edge region can be much too thick, thus it has to be thinned. To achieve this, the non-maximum suppression is used. Every pixel with at least one of its neighbors having larger gradient is no longer considered to be an edge pixel (only neighbors in the direction of pixel's gradient matter).

The positions of found edges are then determined with subpixel precision. The so extracted edges can then undergo further post-processing, if necessary. An edge can be joined with another one in its vicinity, but only if the distance between them is not greater than **inMaxJoiningDistance** and neither of them forms an angle greater than **inMaxJoiningAngle** with the segment connecting their endings. The **inJoiningEndingLength** parameter determines what part of the edge ending is used to determine above mentioned turn angle. If it is set to Nil, only the last edge segment is decisive. Sometimes two or more edges can be joined with an edge. Because only one of them can be, each of the candidates is evaluated based on the distance from the fixed edge's ending and the turn angle associated with their connection. The greater **inJoiningDistanceBalance** is, the less influence on the evaluation score the latter value has. After the joining phase, edges that are shorter than **inMinEdgeLength** are removed from the final results.

Hints

- Connect an input image to the **inImage** input.
- Start with **inEdgeHysteresis** = 0 and set **inEdgeThreshold** so that each important edge is at least partially detected. Then keep increasing **inEdgeHysteresis** until the edges are detected completely.
- If the edges are rugged or there are too many false edges, then try increasing **inStdDevX**.
- Do not change **inEdgeFilter**.
- Define **inMaxJoiningDistance** and **inMaxJoiningAngle** to fix small discontinuities in the resulting edges. This may be very useful when some gaps appear due to noise, dust or other irregularities that preclude correct object detection.
- Sometimes some of the edges being joined have bent endings and **inMaxJoiningAngle** would have to be large. Increase **inJoiningEndingLength** to 3–5 to improve that.
- Use **inMinEdgeLength** to remove short edges that appear due to noise.

Examples



DetectEdges_AsPaths *performed on the sample image with* ***inEdgeFilter*** *= Canny,* ***inStdDevX*** *= 2.5,* ***inStdDevY*** *= 2.5,* ***inEdgeThreshold*** *= 10,* ***inEdgeHysteresis*** *= 5,* ***inMinEdgeLength*** *= 1000.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

 atl::Optional<float> inJoiningEndingLength,
 float inMinEdgeLength,
 atl::Array<avl::Path>& outEdges,
 avl::Image& diagGradientMagnitudeImage,
 avl::Region& diagEdgeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which edges will be extracted
→	inRoi	Optional<const Region&>		NIL	Region of the image from which edges will be extracted
→	inEdgeMaskFilter	EdgeMaskFilter::Type			Type of edge filter used for computing gradients
→	inEdgeThreshold	float	0.0 – ∞	35.0f	Sufficient edge strength; edges of that strength will always be detected
→	inEdgeHysteresis	float	0.0 – ∞	15.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxJoiningDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between edges that can be joined
→	inMaxJoiningAngle	float	0.0 – 180.0	30.0f	Maximal allowed angle between edges being joined
→	inJoiningDistanceBalance	float	0.0 – 1.0	0.0f	Determines how important distance between edges is according to their angle difference
→	inJoiningEndingLength	Optional<float>	1.0 – ∞	NIL	Determines the length of the edge end used for edge angle computing
→	inMinEdgeLength	float	0.0 – ∞	0.0f	Minimal length of an edge
←	outEdges	Array<Path>&			Paths representing found edges
🔍	diagGradientMagnitudeImage	Image&			Visualization of the gradient magnitude
🔍	diagEdgeRegion	Region&			Region representing found edges

Description

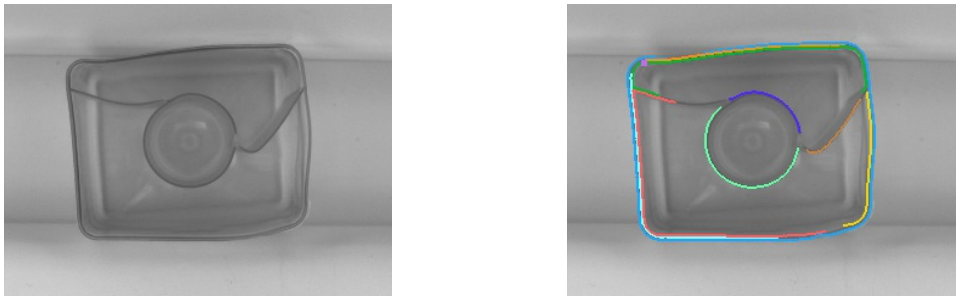
The operation extracts edges from the **inRoi** region in the **inImage** image and stores the result in the array of paths **outEdges**. The extraction process is the same as in DetectEdges_AsRegion_Mask, the only difference being the data type of the result. This filter returns an array of subpixel-precise paths rather than region computed by DetectEdges_AsRegion_Mask.

The extraction process starts from gradient computing, what is done using chosen non-recursive filter with fixed size mask.

On the so computed gradient image threshold with hysteresis (as in ThresholdImage_Hysteresis) is performed with **inEdgeThreshold** and **inEdgeHysteresis** parameters. After this step only gradients which are strong enough are present. The resulting edge region can be much too thick, thus it has to be thinned. To achieve this, the non-maximum suppression is used. Every pixel with at least one of its neighbors having larger gradient is no longer considered to be an edge pixel (only neighbors in the direction of pixel's gradient matter).

The positions of found edges are then determined with subpixel precision. The so extracted edges can then undergo further post-processing, if necessary. An edge can be joined with another one in its vicinity, but only if the distance between them is not greater than **inMaxJoiningDistance** and neither of them forms an angle greater than **inMaxJoiningAngle** with the segment connecting their endings. The **inJoiningEndingLength** parameter determines what part of the edge ending is used to determine above mentioned turn angle. If it is set to Nil, only the last edge segment is decisive. Sometimes two or more edges can be joined with an edge. Because only one of them can be, each of the candidates is evaluated based on the distance from the fixed edge's ending and the turn angle associated with their connection. The greater **inJoiningDistanceBalance** is, the less influence on the evaluation score the latter value has. After the joining phase, edges that are shorter than **inMinEdgeLength** are removed from the final results.

Examples



DetectEdges_AsPaths_Mask *performed on the sample image with* ***inEdgeMaskFilter*** *= Sobel,* ***inEdgeThreshold*** *= 20,* ***inEdgeHysteresis*** *= 5.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported edge mask filter in DetectEdges_AsPaths_Mask.

DetectEdges_AsRegion_Mask

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Extracts a pixel-precise region of continuous edges. Faster, yet less accurate version.

Applications: Consistent detection of pixels that belong to contours of variable or unpredictable shape, e.g. screw thread outline or a custom piece of textile.

Syntax

```
void avl::DetectEdges_AsRegion_Mask
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::EdgeMaskFilter::Type inEdgeMaskFilter,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 float inMaxJoiningDistance,
 const int inMinBlobArea,
 avl::Region& outEdgeRegion,
 avl::Image& diagGradientMagnitudeImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which edges will be extracted
→	inRoi	Optional<const Region&>		NIL	Region of the image from which edges will be extracted
→	inEdgeMaskFilter	EdgeMaskFilter::Type			Type of edge filter used for computing gradients
→	inEdgeThreshold	float	0.0 – ∞	35.0f	Sufficient edge strength; edges of that strength will always be detected
→	inEdgeHysteresis	float	0.0 – ∞	15.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxJoiningDistance	float	0.0 – ∞	0.0f	Maximal distance between edges that can be joined
→	inMinBlobArea	const int	0 – ∞	1	Minimal area of an edge blob
←	outEdgeRegion	Region&			Region of the found edges
🔍	diagGradientMagnitudeImage	Image&			Visualization of the gradient magnitude

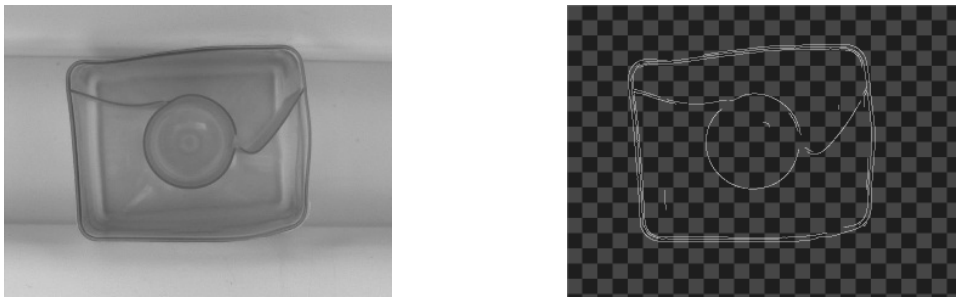
Description

The operation extracts edges from the **inRoi** region in the **inImage** image and stores the result in the **outEdgeRegion** region. The extraction process is the same as in DetectEdges_AsPaths_Mask, the only difference being the data type of the result. This filter returns a region rather than array of subpixel-precise paths computed by DetectEdges_AsPaths_Mask.

The extraction process starts from gradient computing, what is done using chosen non-recursive filter with fixed size mask.

On the so computed gradient image threshold with hysteresis (as in ThresholdImage_Hysteresis) is performed with **inEdgeThreshold** and **inEdgeHysteresis** parameters. After this step only gradients which are strong enough are present. The resulting edge region can be much too thick, thus it has to be thinned. To achieve this, the non-maximum suppression is used. Every pixel with at least one of its neighbors having larger gradient is no longer considered to be an edge pixel (only neighbors in the direction of pixel's gradient matter).

Examples



DetectEdges_AsRegion_Mask *performed on the sample image with* ***inEdgeMaskFilter*** *= Sobel,* ***inEdgeThreshold*** *= 20,* ***inEdgeHysteresis*** *= 5.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported edge mask filter in DetectEdges_AsRegion_Mask.

See Also

- DetectEdges_AsRegion – Extracts a pixel-precise region of continuous edges.
- DetectEdges_AsPaths – Extracts subpixel-precise paths that represent continuous edges.
- DetectEdges_AsPaths_Mask – Extracts subpixel-precise paths that represent continuous edges. Faster, yet less accurate version.

DetectRidges_AsPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Extracts subpixel-precise paths that represent bright or dark thin lines.

Applications: Consistent detection of thin structures like scratches, cracks or lines.

Syntax

```
void avl::DetectRidges_AsPaths
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inRidgeThreshold,
 float inRidgeHysteresis,
 avl::Polarity::Type inPolarity,
 atl::Array<avl::Path>& outRidges
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inStdDevX	float	0.0 – ∞	3.0f	Smoothing standard deviation (horizontal)
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Smoothing standard deviation (vertical, or Auto = horizontal)
→	inRidgeThreshold	float	0.0 – ∞	5.0f	Sufficient ridge strength; ridges of that strength will always be detected
→	inRidgeHysteresis	float	0.0 – ∞	4.0f	Value by which the ridge threshold is decreased for ridge points neighboring with sufficiently strong edges
→	inPolarity	Polarity::Type			
←	outRidges	Array<Path>&			

Hints

- Connect an input image to the **inImage** input.
- Set **inPolarity** in accordance to which type of thin lines you want to detect.
- Start with **inRidgeHysteresis** = 0 and set **inRidgeThreshold** so that each important edge is at least partially detected. Then keep increasing **inRidgeHysteresis** until the edges are detected completely.
- If the edges are rugged or there are too many false edges, then try increasing **inStdDevX**.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

DetectRidges_AsRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Extracts a pixel-precise region of bright or dark thin lines.

Applications: Consistent detection of thin structures like scratches, cracks or lines.

Syntax

```
void avl::DetectRidges_AsRegion
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 float inRidgeThreshold,
 float inRidgeHysteresis,
 avl::Polarity::Type inPolarity,
 const int inMinBlobArea,
 avl::Region& outRidgeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inStdDevX	float	0.0 – ∞	3.0f	Smoothing standard deviation (horizontal)
→	inStdDevY	Optional<float>	0.0 – ∞	NIL	Smoothing standard deviation (vertical, or Auto = horizontal)
→	inRidgeThreshold	float	0.0 – ∞	5.0f	Sufficient ridge strength; ridges of that strength will always be detected
→	inRidgeHysteresis	float	0.0 – ∞	4.0f	Value by which the ridge threshold is decreased for ridge points neighboring with sufficiently strong edges
→	inPolarity	Polarity::Type			
→	inMinBlobArea	const int	0 – ∞	1	Minimal area of a ridge blob
←	outRidgeRegion	Region&			

Hints

- Connect an input image to the **inImage** input.
- Set **inPolarity** in accordance to which type of thin lines you want to detect.
- Start with **inRidgeHysteresis** = 0 and set **inRidgeThreshold** so that each important edge is at least partially detected. Then keep increasing **inRidgeHysteresis** until the edges are detected completely.
- If the edges are rugged or there are too many false edges, then try increasing **inStdDevX**.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

86. Hough Transform

Table of content:

- DetectLines
- DetectMultipleCircles
- DetectPaths
- DetectSegments
- DetectSingleCircle

DetectLines

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds lines in an image using Hough Transform.

Syntax

```
void avl::DetectLines
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inAngleResolution,
 float inMinAngleDelta,
 float inMinDistance,
 float inMinScore,
 float inEdgeThreshold,
 atl::Array<avl::Line2D>& outLines,
 atl::Array<float>& outScores,
 avl::Image& diagGradientMagnitudeImage,
 avl::Image& diagScoreImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inAngleResolution	float	0.1 – 180.0	1.0f	Resolution of lines' orientation
→	inMinAngleDelta	float	0.0 – ∞	20.0f	Minimum angle between two lines
→	inMinDistance	float	0.0 – ∞	20.0f	Minimum distance between two lines
→	inMinScore	float	0.0 – ∞	20.0f	Minimum matching score
→	inEdgeThreshold	float		10.0f	Minimum accepted edge magnitude
←	outLines	Array<Line2D>&			Output lines
←	outScores	Array<float>&			Output scores
🔍	diagGradientMagnitudeImage	Image&			Visualized gradients magnitude of an input image
🔍	diagScoreImage	Image&			Calculated score for each pixel of an input image

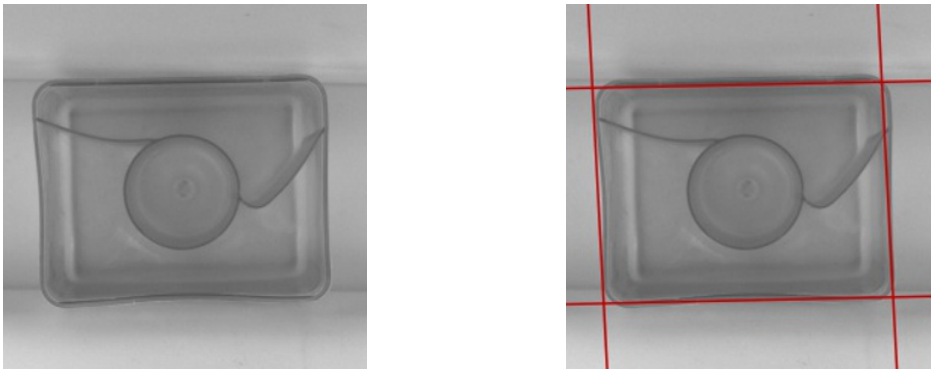
Description

The operation detects straight edges in the **inImage** using the Hough Transform approach and treats them as infinite lines. The output array is ordered from best matching to worst matching results.

The parameter **inAngleResolution** specifies the precision of detected lines' orientations. Value of *n* means the filter will be able to reliably distinguish lines in *n*-degree increments.

Parameters **inMinAngleDelta** and **inMinDistance** are used for neighbouring results suppression. **inMinAngleDelta** specifies the minimum angle between two lines while **inMinDistance** specifies the minimum distance between two parallel lines.

Examples



DetectLines *performed on the sample image with* ***inMinScore*** *= 0.3.*

Remarks

Low values of **inAngleResolution** (under 0.5) may cause high memory consumption and decrease in performance.

See Also

- DetectMultipleCircles – Finds circles of a given radius in the input image using Hough Transform.
- DetectPaths – Finds a specified shape in an image using Hough Transform.
- DetectSegments – Finds segments in an image using Hough Transform.

DetectMultipleCircles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds circles of a given radius in the input image using Hough Transform.

Applications: Detection of circular or close-to-circular objects like holes, pins, pills, particles.

Syntax

```
void avl::DetectMultipleCircles
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inRadius,
 float inMaxOverlap,
 float inMinScore,
 float inEdgeThreshold,
 atl::Array<avl::HoughCircle>& outCircles,
 avl::Image& diagGradientMagnitudeImage,
 avl::Image& diagScoreImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inRadius	float	0.0 – ∞	10.0f	Circles' radius
→	inMaxOverlap	float	0.0 – 1.0	0.1f	Maximum accepted overlapping coefficient
→	inMinScore	float	0.0 – ∞	20.0f	Minimum matching score
→	inEdgeThreshold	float		10.0f	Minimum accepted edge magnitude
←	outCircles	Array<HoughCircle>&			Found circles
🔍	diagGradientMagnitudeImage	Image&			Visualized gradients magnitude of an input image
🔍	diagScoreImage	Image&			Calculated score for each pixel of an input image

Description

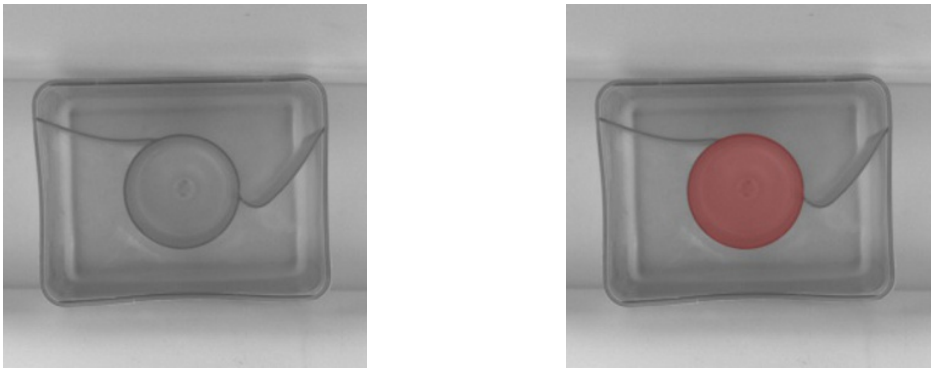
The operation detects circular objects of given radius (in pixels) in the **inImage** using the Hough Transform approach. The output array is ordered from best matching to worst matching results.

The parameter **inMaxOverlap** defines how much the detected circles can overlap. The value of 0 means no overlapping is allowed, and also that each circle must be fully contained in the search ROI, whereas the value of 1 allows full overlapping.

Hints

- Pass an input image to the **inImage** input.
- Define the expected circle radius on the **inRadius** input.
- Set **inEdgeThreshold** to define the minimum strength of edges that will be taken into account. Verify this value with the **diagGradientMagnitudeImage** output.
- Experimentally set the **inMinScore** value, whose meaning is more or less "the number of pixels voting for a particular object location".

Examples



***DetectMultipleCircles** performed on the sample image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- DetectSingleCircle – Finds the strongest circle of a given radius in the input image.
- DetectLines – Finds lines in an image using Hough Transform.
- DetectPaths – Finds a specified shape in an image using Hough Transform.
- DetectSegments – Finds segments in an image using Hough Transform.

DetectPaths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds a specified shape in an image using Hough Transform.

Applications: This is an old algorithm for template matching. Quite slow.

Syntax

```
void avl::DetectPaths
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Path& inPath,
 float inMinScore,
 float inEdgeThreshold,
 atl::Array<avl::Path>& outPaths,
 atl::Array<float>& outScores,
 avl::Image& diagGradientMagnitudeImage,
 avl::Image& diagScoreImage
)
```

Parameters

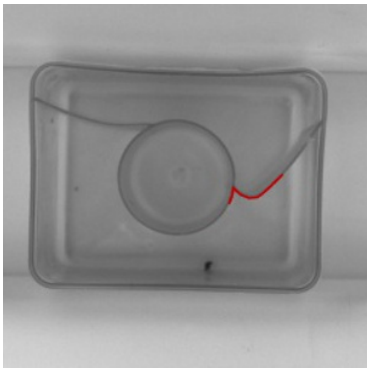
	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inPath	const Path&			Input path
→	inMinScore	float	0.0 – ∞	20.0f	Minimum matching score
→	inEdgeThreshold	float		10.0f	Minimum accepted edge magnitude
←	outPaths	Array<Path>&			Output paths
←	outScores	Array<float>&			Output scores
🔍	diagGradientMagnitudeImage	Image&			Visualized gradients magnitude of an input image
🔍	diagScoreImage	Image&			Calculated score for each pixel of an input image

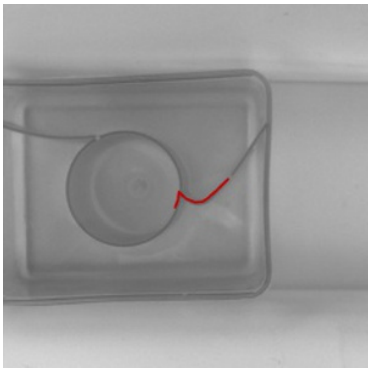
Description

The operation detects paths in the **inImage** using the Generalized Hough Transform approach. The output array is ordered from best matching to worst matching results.

Examples

A sample path (scaled for convenience).





***DetectPaths** performed on the sample images with **inMinScore** = 0.7.*

Remarks

DetectPaths is not scale- or rotation-invariant (slightly scaled or rotated paths are, however, detected properly).

Long **inPath**s cause long computation time.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate path in DetectPaths.

See Also

- DetectLines – Finds lines in an image using Hough Transform.
- DetectMultipleCircles – Finds circles of a given radius in the input image using Hough Transform.
- DetectSegments – Finds segments in an image using Hough Transform.

DetectSegments

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds segments in an image using Hough Transform.

Syntax

```
void avl::DetectSegments
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inAngleResolution,
 float inMinAngleDelta,
 float inMinDistance,
 float inMinLength,
 float inMinScore,
 float inEdgeThreshold,
 atl::Array<avl::Segment2D>& outSegments,
 avl::Image& diagGradientMagnitudeImage,
 avl::Image& diagScoreImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inAngleResolution	float	0.1 – 180.0	1.0f	Resolution of segments' orientation
→	inMinAngleDelta	float	0.0 – ∞	20.0f	Minimum angle between two segments
→	inMinDistance	float	0.0 – ∞	20.0f	Minimum distance between two segments
→	inMinLength	float	0.0 – ∞	20.0f	Minimum segment length
→	inMinScore	float	0.0 – ∞	20.0f	Minimum matching score
→	inEdgeThreshold	float		10.0f	Minimum accepted edge magnitude
←	outSegments	Array<Segment2D>&			Output segments
🔍	diagGradientMagnitudeImage	Image&			Visualized gradients magnitude of an input image
🔍	diagScoreImage	Image&			Calculated score for each pixel of an input image

Description

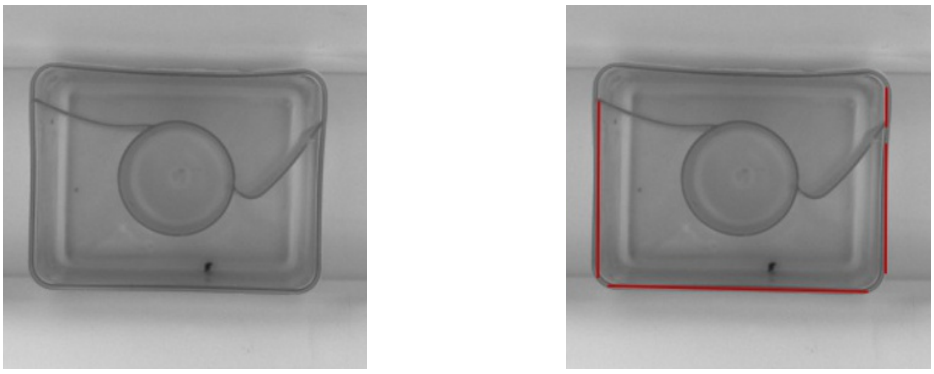
The operation detects straight edges in the **inImage** using the Hough Transform approach and treats them as segments by tracing gradients along lines. The output array is ordered from best matching to worst matching results.

The parameter **inAngleResolution** specifies the precision of detected lines' orientations. Value of *n* means the filter will be able to reliably distinguish lines in *n*-degree increments.

Parameters **inMinAngleDelta** and **inMinDistance** are used for neighbouring results suppression. **inMinAngleDelta** specifies the minimum angle between two lines while **inMinDistance** specifies the minimum distance between two parallel lines. Parameter **inMinLength** limits the length of segments (in pixels), suppressing too short segments.

The orientations of the resulting segments are always between 0 and 180 degrees.

Examples



DetectSegments *performed on the sample image with* ***inMinScore*** *= 0.5,* ***inMinLength*** *= 25.*

Remarks

Low values of **inAngleResolution** (under 0.5) may cause high memory consumption and decrease in performance.

DetectSingleCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds the strongest circle of a given radius in the input image.

Applications: Detection of a circular or close-to-circular object like a hole, pin, pill or particle.

Syntax

```
void avl::DetectSingleCircle
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float inRadius,
 float inMinScore,
 float inEdgeThreshold,
 atl::Conditional<avl::HoughCircle>& outCircle,
 avl::Image& diagGradientMagnitudeImage,
 avl::Image& diagScoreImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Input region of interest
→	inRadius	float	0.0 – ∞	10.0f	Circle's radius
→	inMinScore	float	0.0 – ∞	20.0f	Minimum matching score
→	inEdgeThreshold	float		10.0f	Minimum accepted edge magnitude
←	outCircle	Conditional<HoughCircle>&			Found circle
🔍	diagGradientMagnitudeImage	Image&			Visualized gradients magnitude of an input image
🔍	diagScoreImage	Image&			Calculated score for each pixel of an input image

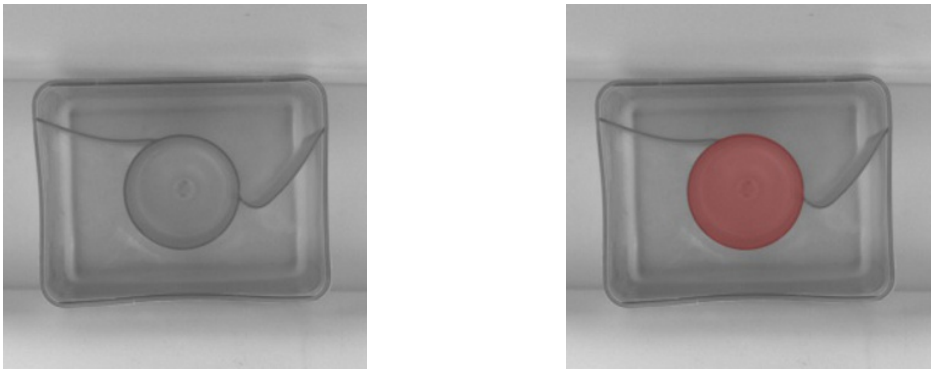
Description

The operation detects circular object of given radius (in pixels) in the **inImage** using the Hough Transform approach.

Hints

- Pass an input image to the **inImage** input.
- Define the expected circle radius on the **inRadius** input.
- Set **inEdgeThreshold** to define the minimum strength of edges that will be taken into account. Verify this value with the **diagGradientMagnitudeImage** output.
- Experimentally set the **inMinScore** value, whose meaning is more or less "the number of pixels voting for a particular object location".

Examples



DetectSingleCircle *performed on the sample image.*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

87. Shape Region Morphology

Table of content:

- DilateShapeRegion
- ErodeShapeRegion

DilateShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological dilation on a shape region.

Applications: Making the shape region thicker or filling-in small holes within it.

Syntax

```
void avl::DilateShapeRegion
(
 const avl::ShapeRegion& inShapeRegion,
 const float inRadius,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inShapeRegion	const ShapeRegion&			
→	inRadius	const float	0.0 – ∞	1.0f	
←	outShapeRegion	ShapeRegion&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Unable to create Polygon from ShapeRegion in DilateShapeRegion.

ErodeShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Performs a morphological erosion on a shape region.

Applications: Making the shape region thinner or removing small parts.

Syntax

```
void avl::ErodeShapeRegion
(
 const avl::ShapeRegion& inShapeRegion,
 const float inRadius,
 avl::ShapeRegion& outShapeRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inShapeRegion	const ShapeRegion&			
→	inRadius	const float	0.0 – ∞	1.0f	
←	outShapeRegion	ShapeRegion&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Unable to create Polygon from ShapeRegion in ErodeShapeRegion.

88. Image Features

DistanceTransform

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an image in which the pixel values denote the estimated distances to the nearest bright pixel in the input image.

Applications: This is an initial step of some advanced traditional image analysis algorithms.

Syntax

```
void avl::DistanceTransform
(
 const avl::Image& inImage,
 int inThreshold,
 float inStraightDistance,
 float inDiagonalDistance,
 float inMaxDistance,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inThreshold	int	0 – +∞	128	Minimal brightness above which pixels are called bright
→	inStraightDistance	float	0.0 – ∞	1.0f	Distance between two neighboring in a row or a column pixels
→	inDiagonalDistance	float	0.0 – ∞	1.414f	Distance between two pixels connected by vertices
→	inMaxDistance	float	0.0 – ∞	255.0f	Maximum value of the calculated distance
←	outImage	Image&			Output distance image

GradientImageRidges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds ridge pixels in a gradient image.

Syntax

```
void avl::GradientImageRidges
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientMaskOperator::Type inOperator,
 avl::MagnitudeMeasure::Type inMeasure,
 avl::NonMaximaMethod::Type inMethod,
 int inMinValue,
 avl::Region& outRegion,
 avl::Image& outMagnitude = atl::Dummy<avl::Image>()
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inOperator	GradientMaskOperator::Type	Sobel	Gradient operator
→	inMeasure	MagnitudeMeasure::Type	Hypot	Gradient magnitude measure
→	inMethod	NonMaximaMethod::Type	InterpolatedPlus	Ridge computation method
→	inMinValue	int	4	Minimum gradient magnitude of a ridge
←	outRegion	Region&		Output region
←	outMagnitude	Image&	Dummy<Image>()	

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in GradientImageRidges.

GradientImageRidges_Sparse

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds ridge pixels in a gradient image.

Syntax

```
void avl::GradientImageRidges_Sparse
(
 const avl::Image& inImage,
 const avl::Image& inMagnitude,
 atl::Optional<const avl::Region&> inRoi,
 int inMinValue,
 avl::SparseImage& outSparseImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inMagnitude	const Image&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inMinValue	int	4	Minimum gradient magnitude of a ridge
←	outSparseImage	SparseImage&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Different input images sizes in GradientImageRidges_Sparse.

Also in AVL Lite

ImageCenter

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the geometrical center of an image.

Syntax

```
void avl::ImageCenter
(
 const avl::Image& inImage,
 avl::Point2D& outCenter
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outCenter	Point2D&		

ImageHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the histogram of the image pixel values.

Syntax

```
void avl::ImageHistogram
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 int inChannelIndex,
 float inDomainBegin,
 const float inBinSize,
 int inBinCount,
 avl::Histogram& outHistogram
)
```

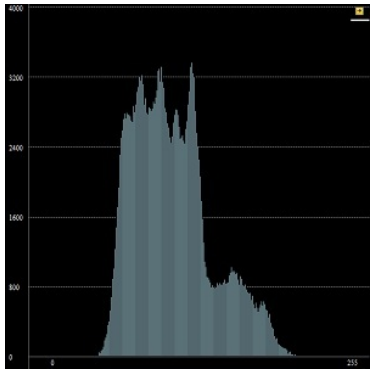
Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inChannelIndex	int	0 – 3		Selects a channel of the input image
→	inDomainBegin	float		0.0f	The lowest value that will be considered in the output histogram
→	inBinSize	const float	0.0 – ∞	1.0f	Width of a single histogram bin
→	inBinCount	int		256	The upper-bound for values that will be considered in the output histogram
←	outHistogram	Histogram&			Output histogram

Description

Histogram in Aurora Vision Studio is a graphical representation of data contained in image. That is, the resulting histogram contains number of pixel values from specified channel with selected **inBinSize** (interval).

Examples



***ImageHistogram** performed on the Lena image with **inChannelIndex** = 0, **inBinSize** = 1.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageHistogram.
DomainError	Selected bin size equals zero in ImageHistogram.
DomainError	Selected channel index is out of range in ImageHistogram.

See Also

- MakeHistogram – Creates a histogram out of an array of bin values.

ImageLocalMaxima

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Finds image locations characterized by locally maximal pixel values.

Applications: Detection of characteristic points, usually after some image transformations.

Syntax

```
void avl::ImageLocalMaxima
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 bool inConsiderPlateaus,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 float inMinDistance,
 atl::Optional<const avl::ImageLocalExtremaVerification&> inMaximaVerification,
 atl::Optional<atl::Array<avl::Extremum2D>&> outLocalMaxima,
 atl::Optional<atl::Array<avl::Region>&> outMaximaRegions = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inConsiderPlateaus	bool			Consider multi-pixel maxima (plateaus) or not
→	inMinValue	Optional<float>		NIL	Minimal value of maximum to be considered
→	inMaxValue	Optional<float>		NIL	Maximal value of maximum to be considered
→	inMinDistance	float	0.0 – ∞		Minimal distance between two found maxima
→	inMaximaVerification	Optional<const ImageLocalExtremaVerification&>		NIL	Maxima verification structure
←	outLocalMaxima	Optional<Array<Extremum2D>&>			Found local maxima
←	outMaximaRegions	Optional<Array<Region>&>		NIL	Regions of local maxima (plateaus and singletons)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLocalMaxima**, **outMaximaRegions**.

Read more about Optional Outputs.

Description

The operation finds local maxima on the image **inImage** within specific region **inRoi**.

It returns three arrays of the same length:

- Subpixel precise positions of the maxima
- Values of the maxima
- Regions of equally bright pixels around the maxima

If the given image consists of more than one channel, they are averaged to obtain monochromatic image, so that the values of the extrema are of type float.

There are two types of local extrema:

- Peak/hole: single pixel (strictly) brighter/darker than its neighbourhood (eight pixels). The extremum's position is determined with subpixel precision using gradient method with Sobel gradient. Returned region contains only one pixel.
- Plateau/lowland: a connected set of equally bright pixels (strictly) brighter/darker from their neighbourhood. Returned position for this extremum is the center of mass of the plateau.

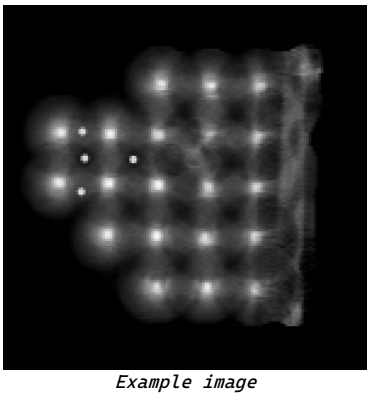
If parameter **inConsiderPlateaus** is set to true, the filter finds both types. Otherwise, it finds only strict maxima.

Parameter **inMinValue** determines the minimal value of the maximum to be considered.

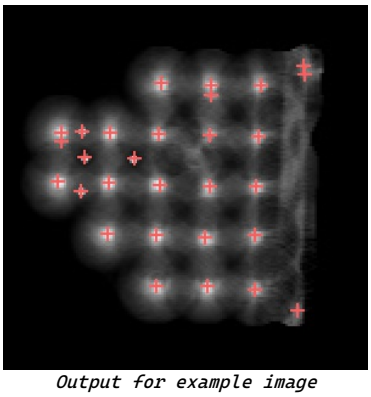
Hints

- If some points are not detected, try decreasing **inMinValue** or setting **inConsiderPlateaus** to **True**.
- Consider adding some Gaussian smoothing before this function.

Examples



Example image



Output for example image

Remarks

If a plateau/lowland is concave, it's center of mass may lie outside it. In such case, the value of the extremum (which is equal to the common value of its pixels) may be different from the value of pixel indicated by position of the extremum.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageLocalMaxima.

See Also

- ImageLocalMinima – Finds image locations characterized by locally minimal pixel values.

ImageLocalMinima

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds image locations characterized by locally minimal pixel values.

Applications: Detection of characteristic points, usually after some image transformations.

Syntax

```
void avl::ImageLocalMinima
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 bool inConsiderLowlands,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 float inMinDistance,
 atl::Optional<const avl::ImageLocalExtremaVerification&> inMinimaVerification,
 atl::Optional<atl::Array<avl::Extremum2D>&> outLocalMinima,
 atl::Optional<atl::Array<avl::Region>&> outMinimaRegions = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inConsiderLowlands	bool			Consider multi-pixel minima (lowlands) or not
→	inMinValue	Optional<float>		NIL	Minimal value of minimum to be considered
→	inMaxValue	Optional<float>		NIL	Maximal value of minimum to be considered
→	inMinDistance	float	0.0 – ∞		Minimal distance between two found minima
→	inMinimaVerification	Optional<const ImageLocalExtremaVerification&>		NIL	Minima verification structure
←	outLocalMinima	Optional<Array<Extremum2D>&>			Found local minima
←	outMinimaRegions	Optional<Array<Region>&>		NIL	Regions of local minima (plateaus and singletons)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLocalMinima**, **outMinimaRegions**.

Read more about Optional Outputs.

Description

The operation finds local minima on the image **inImage** within specific region **inRoi**.

It returns three arrays of the same length:

- Subpixel precise positions of the minima
- Values of the minima
- Regions of equally bright pixels around the minima

If the given image consists of more than one channel, they are averaged to obtain monochromatic image, so that the values of the extrema are of type float.

There are two types of local extrema:

- Peak/hole: single pixel (strictly) brighter/darker than its neighbourhood (eight pixels). The extremum's position is determined with subpixel precision using gradient method with Sobel gradient. Returned region contains only one pixel.
- Plateau/lowland: a connected set of equally bright pixels (strictly) brighter/darker from their neighbourhood. Returned position for this extremum is the center of mass of the plateau.

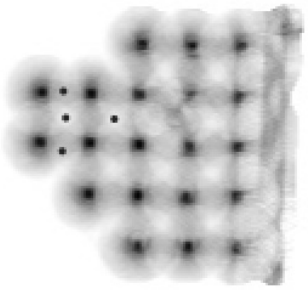
If parameter **inConsiderLowlands** is set to true, the filter finds both types. Otherwise, it finds only strict minima.

Parameter **inMaxValue** determines the maximal value of the minimum to be considered.

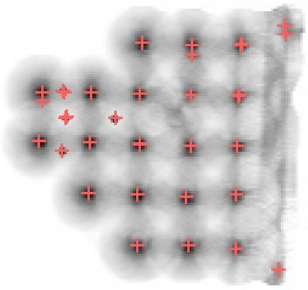
Hints

- If some points are not detected, try decreasing **inMaxValue** or setting **inConsiderLowlands** to **True**.
- Consider adding some Gaussian smoothing before this function.

Examples



Example image



Output for example image

Remarks

If a plateau/lowland is concave, it's center of mass may lie outside it. In such case, the value of the extremum (which is equal to the common value of its pixels) may be different from the value of pixel indicated by position of the extremum.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageLocalMinima.

See Also

- ImageLocalMaxima – Finds image locations characterized by locally maximal pixel values.

ImageMassCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a point with coordinates equal to image mass center in brightness scale.

Syntax

```
void avl::ImageMassCenter
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Point2D& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outMassCenter	Point2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Black image on input in ImageMassCenter.
DomainError	Empty region on input in ImageMassCenter.
DomainError	Region exceeds an input image in ImageMassCenter.

ImageMoment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the selected moment of an image in regular and normalized (divided by sum of pixel values) variant.

Syntax

```
void avl::ImageMoment
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::ImageMomentType::Type inMomentType,
 bool inCentral,
 float& outMoment,
 atl::Optional<float&> outNormMoment = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inMomentType	ImageMomentType::Type		
→	inCentral	bool		
←	outMoment	float&		
←	outNormMoment	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outNormMoment**.

Read more about Optional Outputs.

Description

The operation computes the mathematical features of an image called moments. Those are sums computed as follows:

$$
\begin{aligned}
Moment_{0,0}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot 1 \\
Moment_{0,1}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot p_y \\
Moment_{1,0}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot p_x \\
Moment_{0,2}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot p_y^2 \\
Moment_{1,1}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot p_x p_y \\
Moment_{2,0}(Image, Roi) &= \sum_{p \in Roi} Image(p_x, p_y) \cdot p_x^2
\end{aligned}
$$

The summing is conducted over all pixels in **inRoi** region, while p_x and p_y denote, accordingly, x and y coordinate of a pixel.

When **inCentral** parameter is set, the image is shifted before computations, so that its mass center is at location (0,0).

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Black image on input in ImageMoment.
DomainError	Empty region on input in ImageMoment.
DomainError	Region exceeds an input image in ImageMoment.

See Also

- RegionMoment – Computes selected second-order moment of a region in regular and normalized (divided by region area) variant.

Also in AVL Lite

ImageOrientation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the orientation of an image using image moments. The result range is from 0.0 to 180.0.

Syntax

```
void avl::ImageOrientation
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float& outOrientationAngle
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outOrientationAngle	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Black image on input in ImageOrientation.
DomainError	Empty region on input in ImageOrientation.
DomainError	Region exceeds an input image in ImageOrientation.

Also in AVL Lite

ImagePixels

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns an array of pixels from the input image.

Syntax

```
void avl::ImagePixels
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Array<avl::Pixel>& outPixels
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outPixels	Array<Pixel>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImagePixels.

ImagePixelValues

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns an array of pixel values from the input image.

Syntax

```
void avl::ImagePixelValues
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 atl::Array<float>& outPixelValues
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outPixelValues	Array<float>&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImagePixelValues.

ImageProfileAlongPath

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates a series of segments across the input path, measures the average pixel intensity on each of the segments, and creates the final profile from those values.

Applications: This is the first step of all 1D Edge Detection operations. Here available for direct use by the user.

Syntax

```
void avl::ImageProfileAlongPath
(
 ScanMapState& ioState,
 const avl::Image& inImage,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 int inScanWidth,
 const avl::SamplingParams& inSamplingParams,
 float inSmoothingStdDev,
 avl::AccumulationMode::Type inAccumulationMode,
 atl::Optional<avl::Pixel> inBorderColor,
 avl::Profile& outProfile,
 avl::Path& outPath,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints,
 float& diagSamplingStep
)
```

Parameters

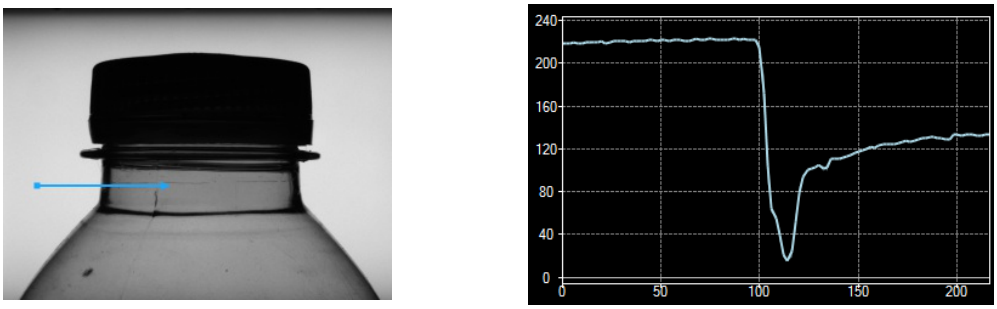
	Name	Type	Range	Default	Description
	ioState	ScanMapState&			Object used to maintain state of the function.
	inImage	const Image&			Input image
	inScanPath	const Path&			Path along which the profile is extracted
	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
	inScanWidth	int	1 – ∞	5	Width of the scan field in pixels
	inSamplingParams	const SamplingParams&			Parameters controlling the sampling process
	inSmoothingStdDev	float	0.0 – ∞	0.6f	Standard deviation of the gaussian smoothing applied to the extracted profile
	inAccumulationMode	AccumulationMode::Type			Determines how the pixel values are combined
	inBorderColor	Optional<Pixel>		Pixel (X: 0.0f Y: 0.0f Z: 0.0f W: 0.0f)	Color of pixel outside image
	outProfile	Profile&			The resulting profile of the pixel brightness
	outPath	Path&			The path consisting of the points from which the resulting profile is extracted
	outAlignedScanPath	Optional<Path&>		NIL	Input scan path after transformation (in the image coordinates)
	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile
	diagSamplingStep	float&			Used distance between consecutive sampling points on the scan path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**.

Read more about Optional Outputs.

Examples



ImageProfileAlongPath *applied on an image of a bottle (**inScanWidth** = 5)*

Also in AVL Lite

ImageProjection

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average (or other statistic) for each image row or column and then merges the obtained results into a profile.

Syntax

```
void avl::ImageProjection
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::ProjectionDirection::Type inProjectionDirection,
 avl::ProjectionMode::Type inProjectionMode,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Monochromatic image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inProjectionDirection	ProjectionDirection::Type		Combine pixel values for image rows (horizontal) or columns (vertical)
→	inProjectionMode	ProjectionMode::Type	Sum	Determines how the pixel values are combined
←	outProfile	Profile&		Output profile

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Description

Computes the average (or other statistic) for each image row or column and then merges the obtained results into a profile.

Examples

ImageProjection *performed on a lena sample.*

Mode	Horizontal Direction	Vertical Direction
Sum		Average		
Maximum		Minimum		
Median		
Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageProjection.
DomainError	Not supported inImage pixel format in ImageProjection. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

ImageRidges

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds ridge pixels in an image.

Syntax

```
void avl::ImageRidges
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Polarity::Type inPolarity,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 const float inNoiseLevel,
 avl::Region& outRidges
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inPolarity	Polarity::Type			Specifies the type of ridges to be detected (Bright, Dark or Any)
→	inMinValue	Optional<float>		NIL	Minimal value of pixel to be considered
→	inMaxValue	Optional<float>		NIL	Maximal value of pixel to be considered
→	inNoiseLevel	const float	0.0 – ∞		Defines how much stronger a pixel has to be than its neighbors to be deemed a ridge pixel
←	outRidges	Region&			Region of ridges

Description

The operation finds region of pixels being local ridges on the image **inImage** within specific region **inRoi**. For a pixel to be deemed a ridge pixel it is necessary to be stronger than both its neighbor pixels in at least one from four main directions (horizontal, vertical and two diagonals) by at least **inNoiseLevel**. Furthermore, the pixel value must be between **inMinValue** and **inMaxValue**.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageRidges.

See Also

- ImageLocalMinima – Finds image locations characterized by locally minimal pixel values.
- ImageLocalMaxima – Finds image locations characterized by locally maximal pixel values.

ImageSharpness

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns a value dependent on sharpness of the image. The value is bigger for sharper images.

Applications: Designed for manual or automatic camera focus adjustment.

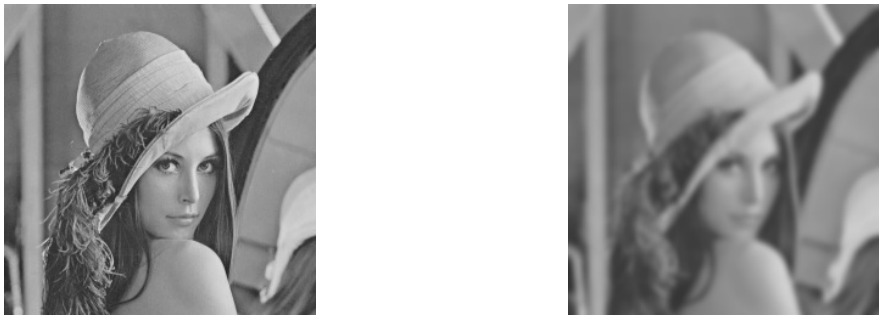
Syntax

```
void avl::ImageSharpness
(
 const avl::Image& inImage,
 atl::Optional<const avl::Box&> inRoi,
 float& outSharpness
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Box&>	NIL	Range of pixels to be processed
←	outSharpness	float&		

Examples



Two images having different sharpness level – 38.326 for the left one, 6.059 for the right one.

Errors

List of possible exceptions:

Error type	Description
DomainError	inRoi exceeds image dimensions in ImageSharpness.

ImageStandardDeviation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Calculates standard deviation of image pixel values.

Syntax

```
void avl::ImageStandardDeviation
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 float& outStandardDeviation
)
```

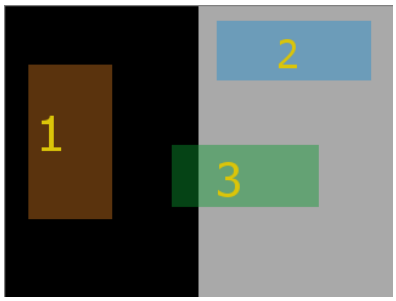
Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image.
→	inRoi	Optional<const Region&>	NIL	Region of Interest.
←	outStandardDeviation	float&		Calculated standard deviation.

Description

Computes how input image pixel values are spread out.

Examples



ImageStandardDeviation *yielded 0.0 for regions 1 and 2, but 93.3 for 3.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ImageStandardDeviation.

Also in AVL Lite

DrawArc

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws an arc on an image.

Syntax

```
void avl::DrawArc
(
 avl::Image& ioImage,
 const avl::Arc2D& inArc,
 atl::Optional<const avl::CoordinateSystem2D&> inArcAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inArc	const Arc2D&		
	inArcAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		

Also in AVL Lite

DrawBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a box on an image.

Syntax

```
void avl::DrawBox
(
 avl::Image& ioImage,
 const avl::Box& inBox,
 const avl::Pixel& inColor,
 const float inOpacity
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inBox	const Box&			
	inColor	const Pixel&			
	inOpacity	const float	0.0 – 1.0	1.0f	

DrawCircle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a circle on an image.

Syntax

```
void avl::DrawCircle
(
 avl::Image& ioImage,
 const avl::Circle2D& inCircle,
 atl::Optional<const avl::CoordinateSystem2D&> inCircleAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inCircle	const Circle2D&		
	inCircleAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		

Description

The operation draws a single of circle on the **ioImage**. Circle may exceed the image dimensions - those will be drawn partially or not at all, but the filter execution will succeed.

See Also

- DrawPoints_MultiColor - Draws points on an image with multiple colors.
- DrawPoints_SingleColor - Draws points on an image with a single color.

DrawCoordinateSystem

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a pair of arrows representing a coordinate system on an image.

Syntax

```
void avl::DrawCoordinateSystem
(
 avl::Image& ioImage,
 const avl::CoordinateSystem2D& inCoordinateSystem,
 atl::Optional<const avl::CoordinateSystem2D&> inCoordinateSystemAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 const float inArrowSize,
 const float inPixelScale
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inCoordinateSystem	const CoordinateSystem2D&			
	inCoordinateSystemAlignment	Optional<const CoordinateSystem2D&>		NIL	
	inColor	const Pixel&			
	inDrawingStyle	const DrawingStyle&			
	inArrowSize	const float	0.0 – ∞	5.0f	
	inPixelScale	const float	0.0 – ∞	20.0f	How many pixels long will be axis of a coordinate system with unit scale

DrawCrosshair

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a crosshair on an image.

Syntax

```
void avl::DrawCrosshair
(
 avl::Image& ioImage,
 const avl::Location& inLocation,
 atl::Optional<const avl::CoordinateSystem2D&> inLocationAlignment,
 const avl::Pixel& inColor,
 const avl::CrosshairShape::Type inCrosshairShape,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inLocation	const Location&		
	inLocationAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inCrosshairShape	const CrosshairShape::Type		
	inDrawingStyle	const DrawingStyle&		

DrawDimensionLine

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a dimension line on an image.

Syntax

```
void avl::DrawDimensionLine
(
 avl::Image& ioImage,
 const avl::Segment2D& inSegment,
 atl::Optional<const avl::CoordinateSystem2D&> inSegmentAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 float inHeadSize,
 float inScale,
 avl::MetricUnit::Type inMetricUnit,
 const int inFractionalDigitCount,
 float inTextSize = 12
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inSegment	const Segment2D&			
	inSegmentAlignment	Optional<const CoordinateSystem2D&>		NIL	
	inColor	const Pixel&			
	inDrawingStyle	const DrawingStyle&			
	inHeadSize	float	0.0 – ∞	5.0f	
	inScale	float	0.0 – ∞	1.0f	px / mm
	inMetricUnit	MetricUnit::Type		Millimetres	
	inFractionalDigitCount	const int	0 – 100	3	How many characters the fractional part of the number should have
	inTextSize	float	10.0 – ∞	12.0f	

Also in AVL Lite

DrawEllipse

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws an ellipse on an image.

Syntax

```
void avl::DrawEllipse
(
 avl::Image& ioImage,
 const avl::Rectangle2D& inEllipse,
 atl::Optional<const avl::CoordinateSystem2D&> inEllipseAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
↔	ioImage	Image&		
→	inEllipse	const Rectangle2D&		
→	inEllipseAlignment	Optional<const CoordinateSystem2D&>	NIL	
→	inColor	const Pixel&		
→	inDrawingStyle	const DrawingStyle&		

Also in AVL Lite

DrawGridImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws an image as a tile on an image considered to be a grid of tiles.

Syntax

```
void avl::DrawGridImage
(
 avl::Image& ioImage,
 const avl::Image& inTileImage,
 int inColumnIndex,
 int inRowIndex,
 atl::Optional<int> inGridWidth,
 atl::Optional<int> inGridHeight
)
```

Parameters

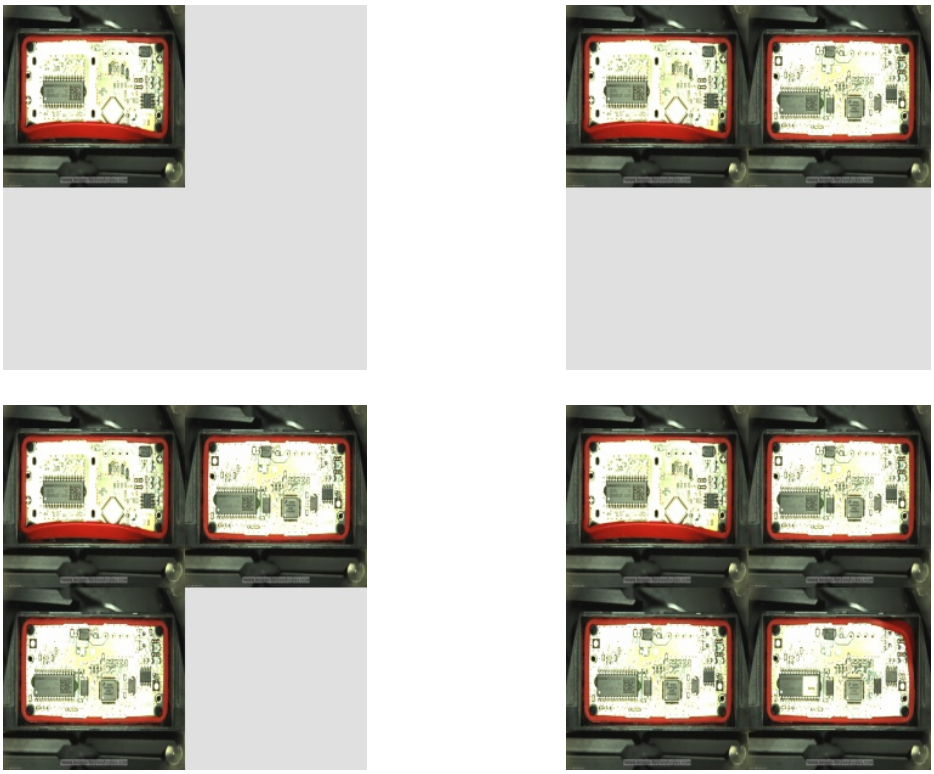
	Name	Type	Range	Default	Description
↔	ioImage	Image&			
→	inTileImage	const Image&			Image to be pasted to the grid
→	inColumnIndex	int			Column index in the grid
→	inRowIndex	int			Row index in the grid
→	inGridWidth	Optional<int>	1 – ∞	NIL	
→	inGridHeight	Optional<int>	1 – ∞	NIL	

Description

The operation supports drawing image grids composed of equally sized images. The filters draws single **inImage** on the **inImage** at the location being the selected multiple of **inTileImage** dimensions.

Parameters pair **inColumnIndex** and **inRowIndex** set to (0, 0) draws **inTileImage** at the location of (0,0) pixels of the **inImage**.

Examples



*Four consecutive instances of the **DrawGridImage** used to plot an image grid. Each of the filters receives different **inImage** and different pair of the **inColumnIndex**, **inRowIndex** parameters – accordingly: (0,0) (0,1) (1,0) (1,1).*

See Also

- DrawImage – Draws an image on another one.
- JoinImages – Creates a single image by glueing together the two input images in horizontal or vertical direction.
- ComposeImages – Takes pixels from the first image within the specified region and from the other one elsewhere.

DrawImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws an image on another one.

Syntax

```
void avl::DrawImage
(
 avl::Image& ioImage,
 const avl::Image& inDrawnImage,
 const avl::Location& inLocation
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inDrawnImage	const Image&		Image to be pasted on ioImage
	inLocation	const Location&		Location at which the image will be pasted

Description

The operation draws the **inDrawnImage** on the **inImage** so that the upper-left corner of the **inDrawnImage** is aligned at the **inLocation** of the **inImage**.

Examples

*The **DrawImage** used to draw an image on another, empty image.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Incompatible image depths in DrawImage.

See Also

- DrawGridImage – Draws an image as a tile on an image considered to be a grid of tiles.

Also in AVL Lite

DrawImagesGrid

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a grid of images.

Syntax

```
void avl::DrawImagesGrid
(
 const atl::Array<avl::Image>& inImages,
 int inColumnCount,
 int inRowCount,
 const atl::Optional<avl::Size>& inTileSize,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImages	const Array<Image>&			Images to be draw
→	inColumnCount	int	1 – ∞	4	Columns count
→	inRowCount	int	1 – ∞	4	Number of rows to be draw
→	inTileSize	const Optional<Size>&		NIL	
←	outImage	Image&			Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	At least one image is required.
DomainError	Number of images exceeds number of cells in the grid.

Also in AVL Lite

DrawLine

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a line on an image.

Syntax

```
void avl::DrawLine
(
 avl::Image& ioImage,
 const avl::Line2D& inLine,
 atl::Optional<const avl::CoordinateSystem2D&> inLineAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
↔	ioImage	Image&		
→	inLine	const Line2D&		
→	inLineAlignment	Optional<const CoordinateSystem2D&>	NIL	
→	inColor	const Pixel&		
→	inDrawingStyle	const DrawingStyle&		

DrawPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a path on an image.

Syntax

```
void avl::DrawPath
(
 avl::Image& ioImage,
 const avl::Path& inPath,
 atl::Optional<const avl::CoordinateSystem2D&> inPathAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inPath	const Path&		Input path
	inPathAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		

Also in AVL Lite

DrawPoint

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a point on an image.

Syntax

```
void avl::DrawPoint
(
 avl::Image& ioImage,
 const avl::Point2D& inPoint,
 atl::Optional<const avl::CoordinateSystem2D&> inPointAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inPoint	const Point2D&		
	inPointAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		

DrawRectangle

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a rectangle on an image.

Syntax

```
void avl::DrawRectangle
(
 avl::Image& ioImage,
 const avl::Rectangle2D& inRectangle,
 atl::Optional<const avl::CoordinateSystem2D&> inRectangleAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle
)
```

Parameters

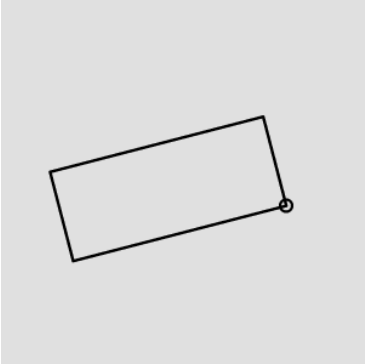
	Name	Type	Default	Description
	ioImage	Image&		
	inRectangle	const Rectangle2D&		
	inRectangleAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		

Description

Filter draws rectangles on an input image.

If an rectangle dimensions exceeds image size it will not be drawn or will be drawn partially.

To indicate the Rectangle orientation set **inDrawingStyle.PointShape** and **inDrawingStyle.Size**.



*Rectangle drawn with set orientation indicator **inDrawingStyle.PointShape** = **Circle** and **inDrawingStyle.Size** = **10**.*

Hints

- Define **inRectangle**. This will be the primitives to be drawn.
- Define **inColor**. Please note, that on an N-channel image only first N components of the color will be used.
- Set **inDrawingStyle** to control quality, opacity, thickness, filling, point shapes and sizes.

DrawRegion

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a region on an image.

Syntax

```
void avl::DrawRegion
(
 avl::Image& ioImage,
 const avl::Region& inRegion,
 atl::Optional<const avl::CoordinateSystem2D&> inRegionAlignment,
 const avl::Pixel& inColor,
 const float inOpacity
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inRegion	const Region&			Input region
	inRegionAlignment	Optional<const CoordinateSystem2D&>		NIL	
	inColor	const Pixel&			
	inOpacity	const float	0.0 – 1.0		

DrawSegment

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a segment on an image.

Syntax

```
void avl::DrawSegment
(
 avl::Image& ioImage,
 const avl::Segment2D& inSegment,
 atl::Optional<const avl::CoordinateSystem2D&> inSegmentAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 const avl::MarkerType::Type inMarkerType,
 const float inMarkerSize
)
```

Parameters

	Name	Type	Range	Default	Description
	ioImage	Image&			
	inSegment	const Segment2D&			
	inSegmentAlignment	Optional<const CoordinateSystem2D&>		NIL	
	inColor	const Pixel&			
	inDrawingStyle	const DrawingStyle&			
	inMarkerType	const MarkerType::Type		Arrow	
	inMarkerSize	const float	0.0 – ∞	5.0f	

DrawShapeRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a shape region on an image.

Syntax

```
void avl::DrawShapeRegion
(
 avl::Image& ioImage,
 const avl::ShapeRegion& inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRegionAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 const bool inForceRgb
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inRoi	const ShapeRegion&		Range of pixels to be processed
	inRegionAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&	DrawingStyle (DrawingMode: HighQuality Opacity: 1.0f Thickness: 1.0f Filled: False PointShape: Nil PointSize: 1.0f)	
	inForceRgb	const bool	True	Filter will convert monochromatic image to RGB if needed

Also in AVL Lite

DrawString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a string on an image.

Syntax

```
void avl::DrawString
(
 avl::Image& ioImage,
 const atl::String& inString,
 const avl::Location& inLocation,
 atl::Optional<const avl::CoordinateSystem2D&> inLocationAlignment,
 const avl::Anchor2D::Type inLocationAnchor,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 float inSize,
 float inOrientationAngle,
 atl::Optional<const avl::Pixel&> inBackgroundColor
)
```

Parameters

	Name	Type	Default	Description
↔	ioImage	Image&		
→	inString	const String&		
→	inLocation	const Location&		
→	inLocationAlignment	Optional<const CoordinateSystem2D&>	NIL	
→	inLocationAnchor	const Anchor2D::Type	MiddleCenter	
→	inColor	const Pixel&		
→	inDrawingStyle	const DrawingStyle&		
→	inSize	float	12.0f	Height of a character
→	inOrientationAngle	float	0.0f	
→	inBackgroundColor	Optional<const Pixel&>	NIL	

Description

The operation draws a string on the **ioImage** aligning the **inLocationAnchor** location of the text at the **inLocation** of the **ioImage**. The height of the font is fixed and equals **16** pixels.

Usage of DrawString with various settings.

See Also

- DrawLine – Draws a line on an image.

- DrawCircle – Draws a circle on an image.
- DrawRectangle – Draws a rectangle on an image.

DrawVector

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Draws a vector at an associated initial point on an image.

Syntax

```
void avl::DrawVector
(
 avl::Image& ioImage,
 const avl::Vector2D& inVector,
 const avl::Point2D& inInitialPoint,
 atl::Optional<const avl::CoordinateSystem2D&> inVectorAlignment,
 const avl::Pixel& inColor,
 const avl::DrawingStyle& inDrawingStyle,
 const float inHeadSize
)
```

Parameters

	Name	Type	Default	Description
	ioImage	Image&		
	inVector	const Vector2D&		
	inInitialPoint	const Point2D&		
	inVectorAlignment	Optional<const CoordinateSystem2D&>	NIL	
	inColor	const Pixel&		
	inDrawingStyle	const DrawingStyle&		
	inHeadSize	const float	5.0f	

VisualizeHeatmap

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Colorizes heat-map and blends it with background image.

Syntax

```
void avl::VisualizeHeatmap
(
 atl::Optional<const avl::Image&> inImage,
 const avl::Heatmap& inHeatmap,
 const avl::ColorPalette::Type& inPalette,
 atl::Optional<float> inPercentFuzziness,
 bool inForceMono,
 bool inThreshold,
 avl::Image& outImage,
 avl::Image& diagPalette
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	Optional<const Image&>		NIL	Input image
→	inHeatmap	const Heatmap&			Confidence of defect at each pixel
→	inPalette	const ColorPalette::Type&		GreenYellowRed	
→	inPercentFuzziness	Optional<float>	0.0 – ∞	0.0f	
→	inForceMono	bool			Converts input image to monochromatic
→	inThreshold	bool			Remove all values lower than value of minimal threshold.
←	outImage	Image&			Output image
🔍	diagPalette	Image&			Used palette preview

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×uint16, 2×uint8, 2×uint16, 3×uint8, 3×uint16, 4×uint8, 4×uint16.

For input **inHeatmap** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inHeatmap pixel format in VisualizeHeatmap. Supported formats: 1xUInt8.
DomainError	Not supported inImage pixel format in VisualizeHeatmap. Supported formats: 1xUInt8, 1xUInt16, 2xUInt8, 2xUInt16, 3xUInt8, 3xUInt16, 4xUInt8, 4xUInt16.

VisualizeHeatmap_Old

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Colorizes a heat-map and blends it with a background image.

Syntax

```
void avl::VisualizeHeatmap_Old
(
 avl::ColorizeImageState& ioState,
 const avl::Image& inImage,
 const avl::Image& inHeatmap,
 const avl::ColorPalette::Type& inPalette,
 int inThreshold,
 atl::Optional<int> inFuzziness,
 atl::Optional<int> inMinValue,
 atl::Optional<int> inMaxValue,
 bool inForceMono,
 avl::Image& outImage,
 avl::Image& diagPalette
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ColorizeImageState&			Object used to maintain state of the function.
	inImage	const Image&			Input image
	inHeatmap	const Image&			Confidence of defect at each pixel
	inPalette	const ColorPalette::Type&		BlackYellowRed	
	inThreshold	int	0 – 255	64	Minimum defect confidence for choosing more of heat-map color than of input image color
	inFuzziness	Optional<int>	0 – ∞	0	Confidence distance from inThreshold within which heat-map colors and input image colors are linearly interpolated; Auto = INF
	inMinValue	Optional<int>		0	
	inMaxValue	Optional<int>		255	
	inForceMono	bool			Converts input image to monochromatic
	outImage	Image&			Output image
	diagPalette	Image&			Used palette preview

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×uint16, 2×uint8, 2×uint16, 3×uint8, 3×uint16, 4×uint8, 4×uint16.

For input **inHeatmap** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Image sizes are not equal in VisualizeHeatmap_Old.
DomainError	Input heatmap must have 1xUInt8 format in VisualizeHeatmap_Old.
DomainError	Input image must have UInt8 or UInt16 pixel format in VisualizeHeatmap_Old.
DomainError	Not supported inHeatmap pixel format in VisualizeHeatmap_Old. Supported formats: 1xUInt8.
DomainError	Not supported inImage pixel format in VisualizeHeatmap_Old. Supported formats: 1xUInt8, 1xUInt16, 2xUInt8, 2xUInt16, 3xUInt8, 3xUInt16, 4xUInt8, 4xUInt16.

VisualizeSurface

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Colorizes surface to show it as 2D image.

Syntax

```
void avl::VisualizeSurface
(
 const avl::Surface& inSurface,
 const avl::ColorPalette::Type& inPalette,
 avl::Image& outImage,
 float& outWidthScale,
 float& outHeightScale
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inPalette	const ColorPalette::Type&	BlueGreenRedWhite	
←	outImage	Image&		Output image
←	outWidthScale	float&		
←	outHeightScale	float&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

90. Line Finder

Table of content:

- ExtendSegment
- ExtendSegmentFromPoint
- FindMultipleLines
- FindSingleLine

ExtendSegment

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Extends a segment at both endpoints by walking 1 pixel at a time along the segment direction, stopping when the in-place Sobel gradient magnitude at the next position drops below threshold or the image boundary is reached.

Applications: Refining a segment detected by a line finding tool to its full length within the image.

Syntax

```
void avl::ExtendSegment
(
 const avl::Image& inImage,
 const avl::Segment2D& inSegment,
 float inEdgeThreshold,
 avl::InterpolationMethod::Type inInterpolation,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image (gradient is computed in-place)
→	inSegment	const Segment2D&			Segment to extend
→	inEdgeThreshold	float	0.0 – ∞	10.0f	Minimum Sobel gradient magnitude required to continue extending
→	inInterpolation	InterpolationMethod::Type		Bilinear	NearestNeighbour snaps the walking position to the integer grid; Bilinear samples all Sobel neighbours at real-valued coordinates
←	outSegment	Segment2D&			Extended segment

Description

The operation extends **inSegment** at both endpoints by walking one pixel at a time along the segment direction. At each step the Sobel gradient magnitude is sampled at the new position. Extension stops when the magnitude falls below **inEdgeThreshold** or the image boundary is reached.

Hints

- Apply after a segment detector (e.g. FindSingleLine) to recover the full length of a line when the initial detection stops short of the true endpoint.
- Use **inInterpolation** = Bilinear for sub-pixel sampling accuracy at oblique orientations. NearestNeighbour snaps the walking position to the integer grid and is faster but less accurate.
- Set **inEdgeThreshold** to the minimum acceptable gradient magnitude at the extended endpoints. Lower values allow extension further into faint edge regions; higher values stop earlier.

See Also

- ExtendSegmentFromPoint – Builds a segment from a single point on a line by walking in both directions along the locally estimated line direction, one pixel at a time.
- FindSingleLine – Finds a single straight line within a rectangular scan field.

ExtendSegmentFromPoint

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Builds a segment from a single point on a line by walking in both directions along the locally estimated line direction, one pixel at a time.

Applications: Growing a detected edge point into a full segment when only a point (not a segment) is available from a prior detection step.

Syntax

```
void avl::ExtendSegmentFromPoint
(
 const avl::Image& inImage,
 const avl::Point2D& inPoint,
 float inEdgeThreshold,
 float inRelativeThreshold,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 avl::Segment2D& outSegment,
 atl::Array<avl::Point2D>& outTrackedPoints
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image (gradient is computed in-place)
→	inPoint	const Point2D&			Starting point, expected to lie on or near the line
→	inEdgeThreshold	float	0.0 – ∞	10.0f	Minimum Sobel gradient magnitude required to continue extending
→	inRelativeThreshold	float	0.0 – 1.0	0.1f	Candidate magnitude must be at least this fraction of the running average magnitude
→	inRoi	Optional<const Rectangle2D&>		NIL	Optional rectangle that limits pixel tracking to a specific area
←	outSegment	Segment2D&			Resulting segment spanning the detected line through inPoint
←	outTrackedPoints	Array<Point2D>&			Pixel centers visited during tracking, in processing order

Description

The operation starts from **inPoint**, which is expected to lie on or near an edge, and walks in both directions along the locally estimated edge direction one pixel at a time. At each step, two integer-valued pixel candidates straddling the current path perpendicularly are evaluated; the one with the higher Sobel gradient magnitude is chosen. The direction estimate is updated at each step by averaging with the local edge direction. Extension stops when the gradient at the next position falls below **inEdgeThreshold**, when the gradient falls below **inRelativeThreshold** × the running average, or when the image boundary (or **inRoi**) is reached.

Hints

- Supply a point from a prior detection step (e.g. from ScanSingleEdge or FindSingleLine) as **inPoint**.
- Set **inEdgeThreshold** to match the expected edge contrast. Values between 5 and 15 work for most natural edges under moderate noise.
- Use **inRelativeThreshold** to stop extension when the gradient fades near the true endpoint, preventing the path from drifting along background noise after the edge ends.
- Connect **outTrackedPoints** during development to visualize the pixel-level walking path.

See Also

- ExtendSegment – Extends a segment at both endpoints by walking 1 pixel at a time along the segment direction, stopping when the in-place Sobel gradient magnitude at the next position drops below threshold or the image boundary is reached.
- FindSingleLine – Finds a single straight line within a rectangular scan field.

FindMultipleLines

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Finds multiple straight lines within a rectangular scan field, ordered from highest-scoring to lowest.

Applications: Detection of multiple lines within a single scan field.

Syntax

```
void avl::FindMultipleLines
(
 const avl::Image& inImage,
 const avl::SegmentScanField& inScanField,
 atl::Optional<const avl::CoordinateSystem2D&> inScanFieldAlignment,
 int inScanWidth,
 int inScanStep,
 int inScanLimit,
 const avl::EdgeScanParams& inEdgeScanParams,
 float inPointBlindness,
 float inMaxSlant,
 float inMinLength,
 float inMaxGap,
 int inMinPointCount,
 avl::LineSelection::Type inLineSelection,
 float inLineBlindness,
 avl::EdgeMeasure::Type inEdgeMeasure,
 avl::LineFinderMethod::Type inLineFinderMethod,
 float inMaxPointDeviation,
 float inMaxTurnAngle,
 atl::Optional<avl::LineMEstimator::Type> inOutlierSuppression,
 bool inRefineEndpoints,
 atl::Optional<int> inMaxCount,
 atl::Array<avl::Segment2D>& outLines,
 atl::Array<float>& outLineStrengths,
 atl::Array<avl::Profile>& outResponseProfiles,
 atl::Optional<avl::SegmentScanField&> outAlignedScanField,
 atl::Array<atl::Array<avl::Point2D>>& outSelectedPoints,
 atl::Array<avl::Segment2D>& diagScanLines,
 atl::Array<avl::Point2D>& diagCandidatePoints
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inScanField	const SegmentScanField&			Region where the scans are performed
→	inScanFieldAlignment	Optional<const CoordinateSystem2D&>		NIL	
→	inScanWidth	int	1 – ∞	5	How many pixels are sampled perpendicularly at each scan line's positions
→	inScanStep	int	1 – ∞	10	Pixel distance between the centers of consecutive scan lines
→	inScanLimit	int	1 – ∞	50	Maximum number of scan lines
→	inEdgeScanParams	const EdgeScanParams&		EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 1.2f MinMagnitude: 5.0f EdgeTransition: Any)	Parameters of 1D edge detection along a single scan line
→	inPointBlindness	float	0.0 – 1.0	0.3f	Defines a threshold for rejecting edge points that are weaker than a certain portion of the strongest edge point
→	inMaxSlant	float	0.0 – 45.0	30.0f	Maximum angle deviation of the resulting line from 90 degrees to the scan axis
→	inMinLength	float	0.0 – ∞	10.0f	Minimum length of the resulting line
→	inMaxGap	float	0.0 – ∞	50.0f	Maximum gap within a resulting line
→	inMinPointCount	int	2 – ∞	3	Minimum number of edge points that a resulting line must contain (otherwise it is rejected)
→	inLineSelection	LineSelection::Type		Fittest	Selection criteria for edge lines
→	inLineBlindness	float	0.0 – 1.0	0.4f	Defines a threshold for rejecting entire lines that are weaker than a certain portion of the strongest line
→	inEdgeMeasure	EdgeMeasure::Type		LogMagnitude	Several options for measuring a single edge point
→	inLineFinderMethod	LineFinderMethod::Type		Hough	Several alternative algorithms for finding lines within the detected cloud of edge points
→	inMaxPointDeviation	float	0.0 – ∞	2.5f	Maximum pixel distance between a detected line and its supporting edge points
→	inMaxTurnAngle	float	0.0 – 90.0	10.0f	Maximum turn angle at any interior vertex of the line path
→	inOutlierSuppression	Optional<LineMEstimator::Type>		TheilSen	A method for removing outlying points
→	inRefineEndpoints	bool		True	Turns on a method for refining the length of the detected line
→	inMaxCount	Optional<int>	1 – ∞	100	Maximum number of lines to return
←	outLines	Array<Segment2D>&			
←	outLineStrengths	Array<float>&			
←	outResponseProfiles	Array<Profile>&			Edge response profiles, one per scan line
←	outAlignedScanField	Optional<SegmentScanField&>			
←	outSelectedPoints	Array<Array<Point2D>>&			Lists of points associated with each returned line
🔍	diagScanLines	Array<Segment2D>&			Positions of the scan lines placed within the scan field
🔍	diagCandidatePoints	Array<Point2D>&			Edge points detected on the scan lines, after inPointBlindness filtering

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanField**.

Read more about Optional Outputs.

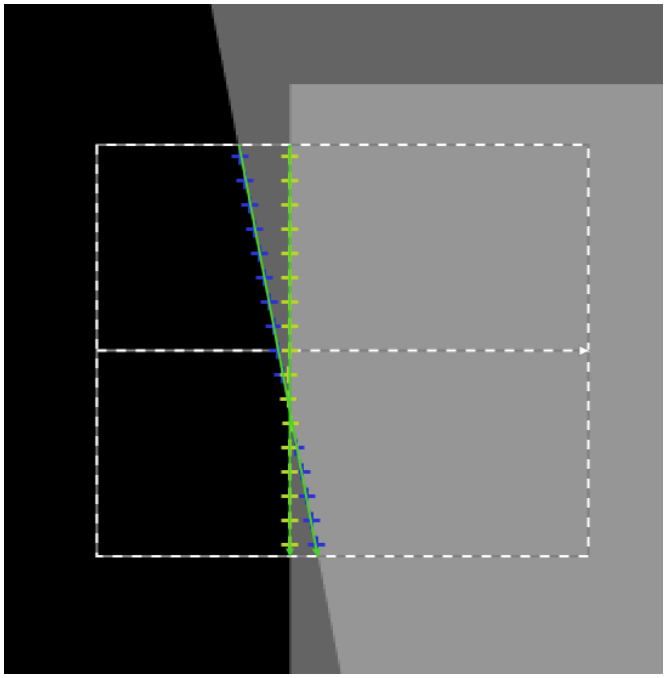
Description

The operation finds all straight lines within the **inScanField** and returns them ordered from the highest-scoring to the lowest. It works like FindSingleLine, but iterates the selection: once a line is accepted, its supporting candidate points are excluded from the competition for subsequent lines, so the results are non-overlapping. Up to **inMaxCount** lines are returned.

Hints

- Activate **diagCandidatePoints** and **diagScanLines** during development to verify that candidates appear on the right scan lines before adjusting higher-level parameters.
- Adjust **inEdgeScanParams.MinMagnitude** first: a value that is too high misses real edges; too low fills the result with noise candidates.
- Increase **inScanStep** to speed up execution on large scan fields. Keep it small (5–10 px) when the line is short or its position varies rapidly across the field.
- **inPointBlindness** suppresses weak per-scan-line candidates relative to the strongest response on that line. A value of 0.3 discards candidates below 30 % of the highest value on that scan line.
- If a detected segment is shorter than the actual line, try increasing **inMaxGap**, widening **inMaxPointDeviation**.
- Set **inMaxSlant** to the maximum expected deviation of the line from the direction perpendicular to the scan field axis. Narrowing this range reduces false positives.
- Use **inLineSelection** = Fittest for the straightest line, Strongest for the highest-contrast line, and Smoothest for gently curved or slightly wavy lines.
- Connect **inScanFieldAlignment** to a coordinate system to automatically adapt the measurement to the object position in each frame.
- Set **inMaxCount** to the exact number of parallel lines expected to prevent spurious detections and unnecessary computation.
- Increase **inLineBlindness** to reject weak secondary lines; decrease it to include fainter candidates.

Examples



FindMultipleLines *locating two intersecting lines. The dashed rectangle is the scan field, the blue and yellow dots are candidates selected for two lines, and the green lines are detected lines.*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- FindSingleLine – Finds a single straight line within a rectangular scan field.

FindSingleLine

Header: AVL.h
Namespace: avl
Module: MetrologyPro

Finds a single straight line within a rectangular scan field.

Applications: Detection of a single straight line in the presence of multiple competing lines or noisy backgrounds.

Syntax

```
void avl::FindSingleLine
(
 const avl::Image& inImage,
 const avl::SegmentScanField& inScanField,
 atl::Optional<const avl::CoordinateSystem2D&> inScanFieldAlignment,

➡	inRefineEndpoints	bool		True	Turns on a method for refining the length of the detected line
⬅	outLine	Conditional<Segment2D>&			
⬅	outLineStrength	Optional<float&>			
⬅	outResponseProfiles	Array<Profile>&			Edge response profiles, one per scan line
⬅	outAlignedScanField	Optional<SegmentScanField&>			
⬅	outSelectedPoints	Array<Point2D>&			List of points associated with the returned line
🔍	diagScanLines	Array<Segment2D>&			Positions of the scan lines placed within the scan field
🔍	diagCandidatePoints	Array<Point2D>&			Edge points detected on the scan lines, after inPointBlindness filtering

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLineStrength**, **outAlignedScanField**.

Read more about Optional Outputs.

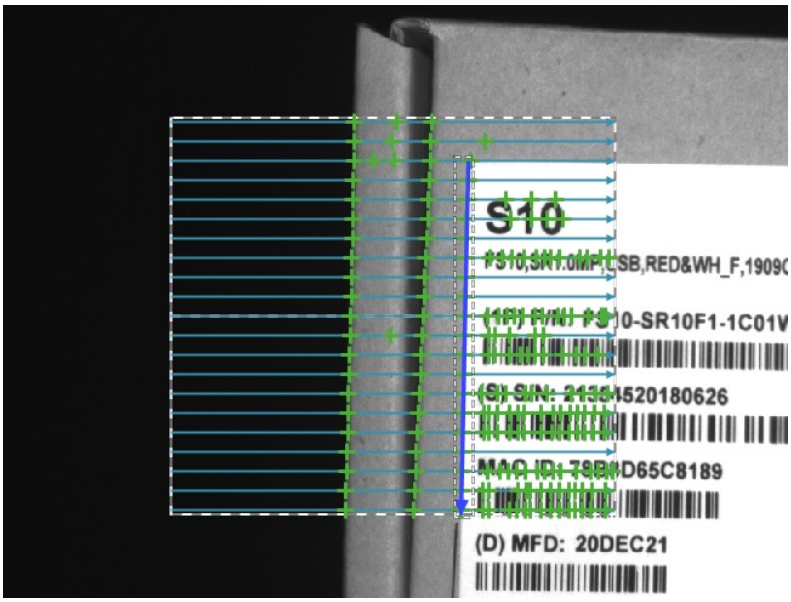
Description

The operation finds the best-fitting straight line within the **inScanField**. Internally, it places up to **inScanLimit** scan lines perpendicular to the field axis, spaced **inScanStep** pixels apart, and detects candidate edge points on each line using **inEdgeScanParams**. The candidate points are assembled into straight-line hypotheses by the algorithm selected with **inLineFinderMethod**, and the best hypothesis is chosen according to **inLineSelection** and refined into a subpixel-precise segment. If no line satisfying the detection constraints is found, **outLine** is set to NIL.

Hints

- Activate **diagCandidatePoints** and **diagScanLines** during development to verify that candidates appear on the right scan lines before adjusting higher-level parameters.
- Adjust **inEdgeScanParams.MinMagnitude** first: a value that is too high misses real edges; too low fills the result with noise candidates.
- Increase **inScanStep** to speed up execution on large scan fields. Keep it small (5–10 px) when the line is short or its position varies rapidly across the field.
- **inPointBlindness** suppresses weak per-scan-line candidates relative to the strongest response on that line. A value of 0.3 discards candidates below 30 % of the highest value on that scan line.
- If a detected segment is shorter than the actual line, try increasing **inMaxGap**, widening **inMaxPointDeviation**.
- Set **inMaxSlant** to the maximum expected deviation of the line from the direction perpendicular to the scan field axis. Narrowing this range reduces false positives.
- Use **inLineSelection** = Fittest for the straightest line, Strongest for the highest-contrast line, and Smoothest for gently curved or slightly wavy lines.
- Connect **inScanFieldAlignment** to a coordinate system to automatically adapt the measurement to the object position in each frame.

Examples



FindSingleLine *locating a single line with* ***inLineSelection*** *= Brightest. The dashed rectangle is the scan field, blue lines are the scan lines, green dots are the candidate edge points, and the blue line is the detected line.*

Remarks

Read more about Local Coordinate Systems in Machine Vision Guide: Local Coordinate Systems.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

ExtractBlobs_Color

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments an image into blobs by color-based thresholding.

Syntax

```
void avl::ExtractBlobs_Color
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::ColorThresholdParams& inThresholdParams,
 const avl::PreSplitProcessingParams& inProcessingParams,
 const avl::SplittingParams& inSplittingParams,
 atl::Array<avl::Region>& outBlobs,
 avl::Region& outBaseRegion
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image from which blobs are extracted
→	inRoi	Optional<const ShapeRegion&>	NIL	Range of pixels to be processed
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the region
→	inThresholdParams	const ColorThresholdParams&		Parameters for color-based thresholding
→	inProcessingParams	const PreSplitProcessingParams&		Parameters for postprocessing of the extracted region
→	inSplittingParams	const SplittingParams&		Parameters for splitting region into blobs
←	outBlobs	Array<Region>&		Blobs extracted from the input image
←	outBaseRegion	Region&		Region of pixels right after thresholding

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 2×uint8, 3×uint8, 4×uint8.

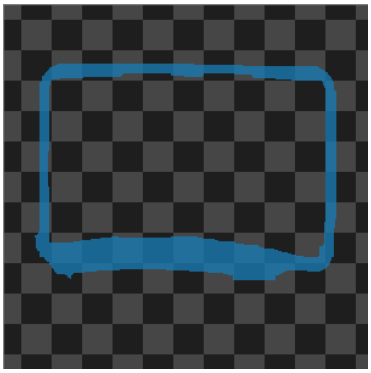
Read more about pixel formats in Image documentation.

Description

This filter can be used to quickly segment an image using color-based thresholding. It performs a series of operations on **inImage**:

- image is thresholded by ThresholdToRegion_Color using parameters from **inThresholdParams**
- resulting region is opened and then closed by OpenRegion and CloseRegion, also holes are removed by FillRegionHoles using parameters from **inProcessingParams**
- resulting region is split into blobs by SplitRegionIntoBlobs using parameters from **inSplittingParams**

Examples



ExtractBlobs_Color *performed on the sample image with* ***inThresholdParams.RgbColor*** *= (189, 36, 25),* ***inThresholdParams.MaxDifference*** *= 40.0 and* ***inProcessingParams.ClosingRadius*** *= 5.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ExtractBlobs_Color.
DomainError	Not supported inImage pixel format in ExtractBlobs_Color. Supported formats: 1xUInt8, 2xUInt8, 3xUInt8, 4xUInt8.

See Also

- ExtractBlobs_Intensity – Segments an image into blobs by thresholding using a single value.
- ExtractBlobs_Dynamic – Segments an image into blobs by dynamic thresholding.

ExtractBlobs_Dynamic

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments an image into blobs by dynamic thresholding.

Syntax

```
void avl::ExtractBlobs_Dynamic
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::DynamicThresholdParams& inThresholdParams,
 const avl::PreSplitProcessingParams& inProcessingParams,
 const avl::SplittingParams& inSplittingParams,
 atl::Array<avl::Region>& outBlobs,
 avl::Region& outBaseRegion
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image from which blobs are extracted
→	inRoi	Optional<const ShapeRegion&>	NIL	Range of pixels to be processed
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the region
→	inThresholdParams	const DynamicThresholdParams&		Parameters for dynamic thresholding
→	inProcessingParams	const PreSplitProcessingParams&		Parameters for postprocessing of the extracted region
→	inSplittingParams	const SplittingParams&		Parameters for splitting region into blobs
←	outBlobs	Array<Region>&		Blobs extracted from the input image
←	outBaseRegion	Region&		Region of pixels right after thresholding

Description

This filter can be used to quickly segment an image with uneven illumination. It performs a series of operations on **inImage**:

- image is thresholded by ThresholdToRegion_Dynamic using parameters from **inThresholdParams**
- resulting region is opened and then closed by OpenRegion and CloseRegion, also holes are removed by FillRegionHoles using parameters from **inProcessingParams**
- resulting region is split into blobs by SplitRegionIntoBlobs using parameters from **inSplittingParams**

Examples

__ExtractBlobs_Dynamic__ performed on the sample image with __inThresholdParams.Polarity__ = Dark, __inThresholdParams.Threshold__ = 5.0, and __inProcessingParams.ClosingRadius__ = 3

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ExtractBlobs_Dynamic.

ExtractBlobs_Intensity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments an image into blobs by thresholding using a single value.

Syntax

```
void avl::ExtractBlobs_Intensity
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::IntensityThresholdParams& inThresholdParams,
 const avl::PreSplitProcessingParams& inProcessingParams,
 const avl::SplittingParams& inSplittingParams,
 atl::Array<avl::Region>& outBlobs,
 avl::Region& outBaseRegion
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image from which blobs are extracted
→	inRoi	Optional<const ShapeRegion&>	NIL	Range of pixels to be processed
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the region
→	inThresholdParams	const IntensityThresholdParams&		Parameters for thresholding an image
→	inProcessingParams	const PreSplitProcessingParams&		Parameters for postprocessing of the extracted region
→	inSplittingParams	const SplittingParams&		Parameters for splitting region into blobs
←	outBlobs	Array<Region>&		Blobs extracted from the input image
←	outBaseRegion	Region&		Region of pixels right after thresholding

Description

This filter can be used to quickly segment an image. It performs a series of operations on **inImage**:

- image is thresholded by ThresholdToRegion using parameters from **inThresholdParams**
- resulting region is opened and then closed by OpenRegion and CloseRegion, also holes are removed by FillRegionHoles using parameters from **inProcessingParams**
- resulting region is split into blobs by SplitRegionIntoBlobs using parameters from **inSplittingParams**

Examples

ExtractBlobs_Intensity *performed on the sample image with* ***inThresholdParams.Polarity*** *= Dark,* ***inThresholdParams.Threshold*** *= 84.0, and* ***inProcessingParams.ClosingRadius*** *= 10.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ExtractBlobs_Intensity.

ExtractBlobs_Range

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments an image into blobs by thresholding using a range of values.

Syntax

```
void avl::ExtractBlobs_Range
(
 const avl::Image& inImage,
 atl::Optional<const avl::ShapeRegion&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 const avl::RangeThresholdParams& inThresholdParams,
 const avl::PreSplitProcessingParams& inProcessingParams,
 const avl::SplittingParams& inSplittingParams,
 atl::Array<avl::Region>& outBlobs,
 avl::Region& outBaseRegion
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Image from which blobs are extracted
→	inRoi	Optional<const ShapeRegion&>	NIL	Range of pixels to be processed
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Adjusts the region
→	inThresholdParams	const RangeThresholdParams&		Parameters for thresholding an image
→	inProcessingParams	const PreSplitProcessingParams&		Parameters for postprocessing of the extracted region
→	inSplittingParams	const SplittingParams&		Parameters for splitting region into blobs
←	outBlobs	Array<Region>&		Blobs extracted from the input image
←	outBaseRegion	Region&		Region of pixels right after thresholding

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ExtractBlobs_Range.

FindMaxStableExtremalRegions

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image by binarizing it with many different thresholds and by looking which blobs appear "stable".

Applications: Most frequently used for finding correspondence points between two images.

Syntax

```
void avl::FindMaxStableExtremalRegions
(
 const avl::Image& inImage,
 const int inDelta,
 const int inMinArea,
 const int inMaxArea,
 const float inMaxVariation,
 const float inMinDiversity,
 avl::RegionConnectivity::Type inConnectivity,
 atl::Array<avl::Region>& outRegions
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inDelta	const int	1 – 255	30	Area variance is calculated against ancestor with color difference of delta
→	inMinArea	const int	0 – ∞	50	Minimum area of stable region
→	inMaxArea	const int	0 – ∞	2000	Maximum area of stable region
→	inMaxVariation	const float	0.0 – ∞	0.1f	Maximum area variance with containing larger region specified by delta parameter, for region to be considered as stable
→	inMinDiversity	const float	0.0 – ∞	2.0f	Minimum area diversity that region must have in order to be stable when compared to stable regions within it
→	inConnectivity	RegionConnectivity::Type		EightDirections	
←	outRegions	Array<Region>&			

Requirements

For input **inImage** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in FindMaxStableExtremalRegions. Supported formats: 1xUInt8.

ImageWatersheds

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes dark basins which are separated by at least inThreshold height watershed.

Syntax

```
void avl::ImageWatersheds
(
 const avl::Image& inImage,
 const int inThreshold,
 atl::Array<avl::Region>& outBasins
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inThreshold	const int	0 – +∞	10	Input minimum separating watershed height
←	outBasins	Array<Region>&			Output dark basins found

SegmentImage_Color

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image basing on distance to model colors.

Applications: Detection of objects of undefined shape, but characterized by uniform color and good contrast to the background.

Syntax

```
void avl::SegmentImage_Color
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const atl::Array<avl::Pixel>& inReferenceColors,
 const float inMaxDifference,
 atl::Optional<const atl::Array<float>&> inDifferenceMultipliers,
 float inChromaAmount,
 bool inForceDisjointRegions,
 atl::Array<avl::Region>& outRegions
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inReferenceColors	const Array<Pixel>&			Colors to compare pixels to
→	inMaxDifference	const float	0.0 – +∞	5.0f	Maximal difference between pixel and reference color to be accepted
→	inDifferenceMultipliers	Optional<const Array<float>&>		NIL	Scales for maximum differences for each color
→	inChromaAmount	float	0.0 – 1.0	0.7f	Proportion of chromatic information in distance computation
→	inForceDisjointRegions	bool			Force output regions to be disjoint
←	outRegions	Array<Region>&			Regions of pixels closest to colors

Description

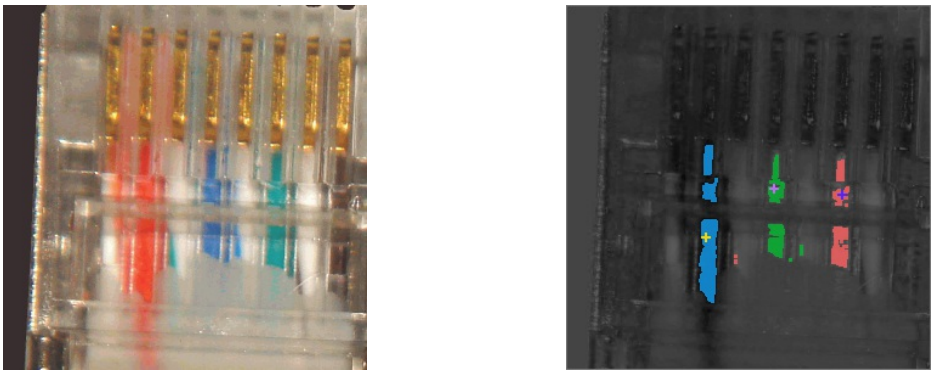
The operation finds regions of similar colors in RGB color space within **inImage**.

First, for each pixel of the input image its distance to each color in **inReferenceColors** is computed (see ColorDistanceImage function).

Then, for each reference color **c**, the function computes region of pixels that are closer to **c** than its corresponding threshold. In case **inDifferenceMultipliers** is **Nil**, threshold is equal to **inMaxDifference**. If **inDifferenceMultipliers** is not **Nil**, corresponding threshold is the product of **inMaxDifference** and the element of **inDifferenceMultipliers** that corresponds to **c**.

If flag **inForceDisjointRegions** is set to True, the regions are forced to be disjoint. In case a pixel has distance less than threshold for more than one color, distances are divided by thresholds and the minimum of ratios is taken. In particular, if the function works in one-threshold mode, the operation described above becomes simply minimum of distances.

Examples



SegmentImage_Color *run with colors taken from three points with* ***inChromaAmount*** *= 0.7 and* ***inMaxDifference*** *= 15*

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent array sizes in SegmentImage_Color.
DomainError	Reference color array size too big in SegmentImage_Color.

See Also

- ColorDistance – Compares two pixels using chromatic and non-chromatic information. Assumes RGB color space.
- ColorDistanceImage – Compares each pixel with the specified color using chromatic and non-chromatic information.

SegmentImage_Edges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image into blobs using image edges as their borders.

Applications: Detection of objects of undefined shape, but characterized by good contrast to the background and fairly uniform internal brightness.

Syntax

```
void avl::SegmentImage_Edges
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const int inFrameSize,
 float inStdDev,
 float inEdgeThreshold,
 float inEdgeHysteresis,
 const float inMaxJoiningDistance,
 const int inMinArea,
 atl::Optional<int> inMaxArea,
 bool inComputeNestingLevels,
 const int inEdgeClosing,
 atl::Array<avl::Region>& outBlobs,
 atl::Optional<atl::Array<int>&> outNestingLevels = atl::NIL,
 avl::Region& diagEdgeRegion = atl::Dummy<avl::Region>()
)
```

Parameters

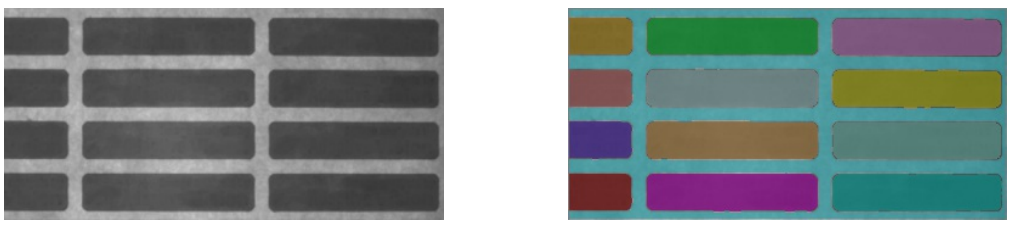
	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which blobs are extracted
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inFrameSize	const int	0 – ∞	1	How many pixels from the region border are excluded from the results
→	inStdDev	float	0.0 – ∞	2.0f	Amount of smoothing used by the edge filter
→	inEdgeThreshold	float	0.0 – ∞	15.0f	Sufficient edge strength; edges of that strength will always be detected
→	inEdgeHysteresis	float	0.0 – ∞	5.0f	Value by which the edge threshold is decreased for edge points neighboring with sufficiently strong edges
→	inMaxJoiningDistance	const float	0.0 – ∞	0.0f	Maximal distance between edges that can be joined
→	inMinArea	const int	0 – ∞	50	Minimal area of a detected blob
→	inMaxArea	Optional<int>	0 – ∞	NIL	Maximal area of a detected blob
→	inComputeNestingLevels	bool			Flag indicating whether nesting levels should be computed
→	inEdgeClosing	const int	0 – ∞	1	Radius of enclosing small holes in the detected blobs
←	outBlobs	Array<Region>&			Blobs extracted from the input image
←	outNestingLevels	Optional<Array<int>&>		NIL	Nesting level of each extracted blob
🔍	diagEdgeRegion	Region&			Region of the found edges

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outNestingLevels**.

Read more about Optional Outputs.

Examples



SegmentImage_Edges *performed on an image of labels; default parameters.*

SegmentImage_Gray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image into blobs examining differences between neighbouring pixels values.

Applications: Detection of objects of undefined shape, but characterized by uniform brightness and good contrast to the background.

Syntax

```
void avl::SegmentImage_Gray
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inMaxDifference,
 const avl::BlobsDifferenceMeasure::Type inDifferenceMeasure,
 const int inMinArea,
 atl::Optional<int> inMaxArea,
 atl::Array<avl::Region>& outBlobs
)
```

Parameters

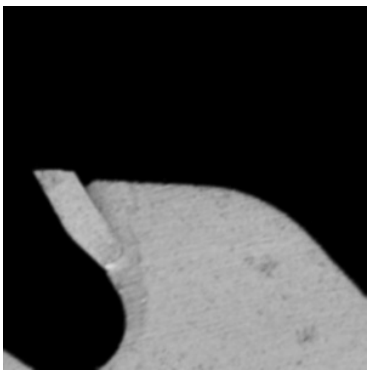
	Name	Type	Range	Default	Description
→	inImage	const Image&			Image from which blobs are extracted
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inMaxDifference	const float	0.0 – ∞	5.0f	Maximal difference between two neighbouring blobs to be merged
→	inDifferenceMeasure	const BlobsDifferenceMeasure::Type		Neighbour	Measure of blobs difference
→	inMinArea	const int	0 – ∞	50	Minimal area of a blob
→	inMaxArea	Optional<int>	0 – ∞	NIL	Maximal area of a blob
←	outBlobs	Array<Region>&			Blobs extracted from the input image

Description

The filter segments the **inImage** image into blobs of adjacent pixels which gray values do not differ too much. The classification is different depending on the **inDifferenceMeasure** method:

- if **Mean** is selected, pixel is considered to belong to an adjacent blob when its value differs by at most **inMaxDifference** from the mean value of this blob's pixels
- if **Neighbour** is selected, two adjacent pixels are considered to belong to the same blob when their values differ by at most **inMaxDifference**

Examples



SegmentImage_Gray *performed on the sample image with* ***inMaxDifference*** *= 55,* ***inDifferenceMeasure*** *= Mean and* ***inMinArea*** *= 50.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported difference measure in SegmentImage_Gray.

See Also

- SegmentImage_Edges – Segments an image into blobs using image edges as their borders.
- SegmentImage_Watersheds – Computes dark or bright watershed basins of an image.

SegmentImage_Gray_Linear

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image into blobs examining differences between pixels values.

Applications: Detection of objects of undefined shape, but characterized by uniform brightness and good contrast to the background.

Syntax

```
void avl::SegmentImage_Gray_Linear
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::BlobMergingMethod::Type inMergingMethod,
 avl::RegionConnectivity::Type inConnectivity,
 int inMaxDifference,
 int inHysteresis,
 int inPassCount,
 bool inDirectional,
 int inMinArea,
 atl::Optional<int> inMaxArea,
 atl::Array<avl::Region>& outBlobs
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inMergingMethod	BlobMergingMethod::Type		Neighbor	Defines a criterion by which two pixels can be merged into one blob
→	inConnectivity	RegionConnectivity::Type			Defines if pixels can be merged only horizontally and vertically, or also diagonally
→	inMaxDifference	int	0 – ∞	5	Maximal tonal difference that allows two pixels to be merged into one blob
→	inHysteresis	int			Total change of MaxDifference during all image passes
→	inPassCount	int	1 – 5		Number of iterations in which the entire image is scanned for pixels that can be merged
→	inDirectional	bool			When 'True' the filter can segment results of GradientDirAndPresenceImage
→	inMinArea	int	0 – ∞	20	Minimal area of a blob that may be accepted
→	inMaxArea	Optional<int>		NIL	Minimal area of a blob that may be accepted
←	outBlobs	Array<Region>&			

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real, 3×uint8, 3×int8, 3×uint16, 3×int16, 3×int32, 3×real.

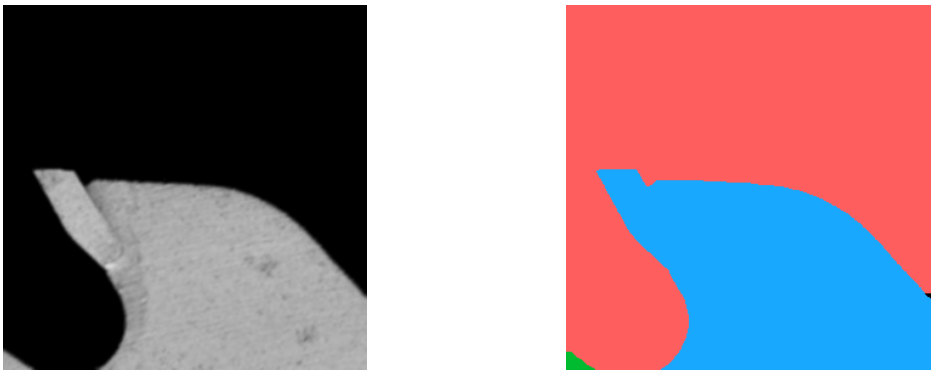
Read more about pixel formats in Image documentation.

Description

The filter segments the **inImage** image into blobs of pixels which gray values do not differ too much. The classification is different depending on the **inMergingMethod** input:

- **Neighbor** – two adjacent pixels are considered to belong to the same blob when their values differ by at most **inMaxDifference**
- **NeighborVerified** – as above, but an additional verification is performed to avoid undersegmentation
- **Mean** – pixel is considered to belong to an adjacent blob when its value differs by at most **inMaxDifference** from the mean value of this blob's pixels
- **MeanSorted** – not implemented in this filter

Examples



SegmentImage_Gray_Linear *performed on the sample image with* ***inMaxDifference*** *= 55,* ***inMergingMethod*** *= MeanLinear and* ***inMinArea*** *= 50.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Directional method only supports single-channel images.
DomainError	Directional method only supports UInt8 images.
DomainError	Two- and four-channel images are not supported in SegmentImage_Gray.
DomainError	Not supported inImage pixel format in SegmentImage_Gray_Linear. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal, 3xUInt8, 3xInt8, 3xUInt16, 3xInt16, 3xInt32, 3xReal.

See Also

- SegmentImage_Gray_Tiled – Segments an image into blobs examining differences between pixels values, first pass is tiled.
- SegmentImage_Edges – Segments an image into blobs using image edges as their borders.
- SegmentImage_Watersheds – Computes dark or bright watershed basins of an image.

SegmentImage_Gray_Tiled

Header: AVL.h
Namespace: avl
Module: FoundationPro

Segments an image into blobs examining differences between pixels values, first pass is tiled.

Applications: Detection of objects of undefined shape, but characterized by uniform brightness and good contrast to the background.

Syntax

```
void avl::SegmentImage_Gray_Tiled
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::BlobMergingMethod::Type inMergingMethod,
 avl::RegionConnectivity::Type inConnectivity,
 int inMaxDifference,
 int inHysteresis,
 bool inTonalDrift,
 bool inDirectional,
 int inMinArea,
 atl::Optional<int> inMaxArea,
 atl::Array<avl::Region>& outBlobs
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inMergingMethod	BlobMergingMethod::Type		Neighbor	Defines a criterion by which two pixels can be merged into one blob
→	inConnectivity	RegionConnectivity::Type			
→	inMaxDifference	int	0 – ∞	5	Maximal tonal difference that allows two pixels to be merged into one blob
→	inHysteresis	int			Change of MaxDifference between first and second iteration
→	inTonalDrift	bool		True	When 'True' blobs can be merged even if the illumination is not even
→	inDirectional	bool			When 'True' the filter can segment results of GradientDirAndPresenceImage
→	inMinArea	int	0 – ∞	20	Minimal area of a blob that may be accepted
→	inMaxArea	Optional<int>		NIL	Minimal area of a blob that may be accepted
←	outBlobs	Array<Region>&			

Requirements

For input **inImage** only pixel formats are supported: 1×uint8, 3×uint8.

Read more about pixel formats in Image documentation.

Description

The filter segments the **inImage** image in two phases. In the first step segmentation is done within tiles, while in the second step blobs are merged between consecutive tiles.

Errors

List of possible exceptions:

Error type	Description
DomainError	Directional method only supports single-channel images.
DomainError	Not supported inImage pixel format in SegmentImage_Gray_Tiled. Supported formats: 1xUInt8, 3xUInt8.

See Also

- SegmentImage_Gray_Linear – Segments an image into blobs examining differences between pixels values.
- SegmentImage_Edges – Segments an image into blobs using image edges as their borders.
- SegmentImage_Watersheds – Computes dark or bright watershed basins of an image.

SegmentImage_Watersheds

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes dark or bright watershed basins of an image.

Applications: A classic algorithm, useful for segmentation of ball-shaped objects like plant seeds, cells or fruits.

Syntax

```
void avl::SegmentImage_Watersheds
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const atl::Array<avl::Region>& inMarkers,
 avl::Polarity::Type inBasinsPolarity,
 atl::Array<avl::Region>& outBasins
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inMarkers	const Array<Region>&		Local minima markers
→	inBasinsPolarity	Polarity::Type		Whether to look for bright or dark basins
←	outBasins	Array<Region>&		

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

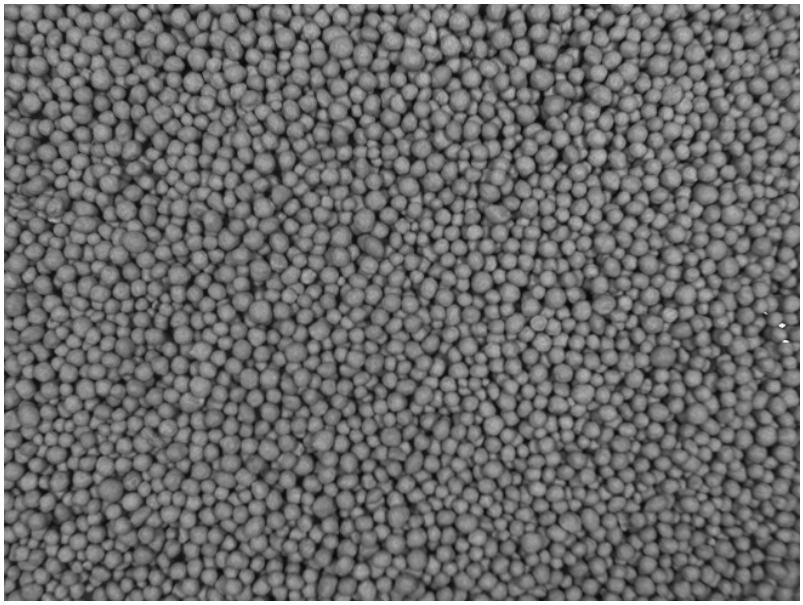
Description

This filter segments the image into basins based on a set of markers (**inMarkers**) and a flooding watersheds implementation for grayscale images.

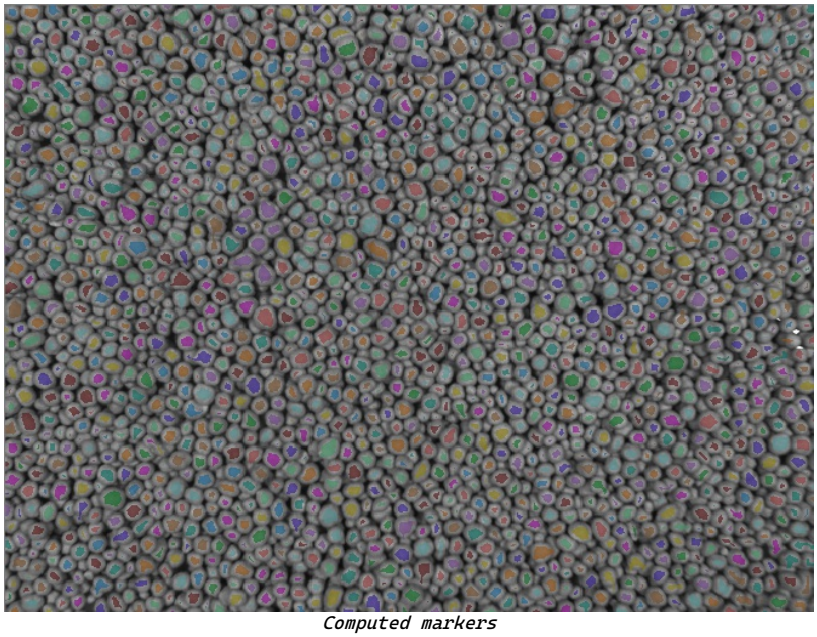
By default a darker pixel is considered lower but that can be changes using the **inBasinsPolarity** parameter.

Markers have to be computed beforehand. One way to do that is to detect the ridges of the image and threshold it into a single region, Pass the resulting region into the **DistanceTransform** filter. Then threshold the distance image and split it into blobs.

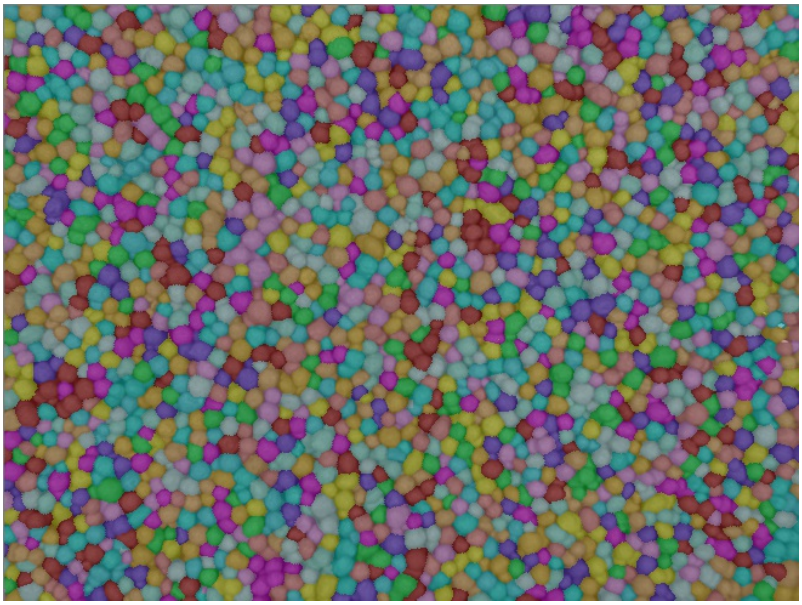
Examples



Example image



Computed markers



Basins computed with watersheds

Errors

List of possible exceptions:

Error type	Description
DomainError	No markers present in SegmentImage_Watersheds.
DomainError	Not supported inImage pixel format in SegmentImage_Watersheds. Supported formats: UInt8.

See Also

- DetectRidges_AsRegion – Extracts a pixel-precise region of bright or dark thin lines.
- ThresholdToRegion – Creates a region containing image pixels with values within the specified range.
- DistanceTransform – Computes an image in which the pixel values denote the estimated distances to the nearest bright pixel in the input image.

FillRegionHoles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Adds pixels to the input region so that it contains no holes.

Syntax

```
void avl::FillRegionHoles
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 int inMinHoleArea,
 atl::Optional<int> inMaxHoleArea,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inConnectivity	RegionConnectivity::Type			Type of connectivity used for the region foreground
→	inMinHoleArea	int	0 – ∞		Minimal area of a hole to be filled
→	inMaxHoleArea	Optional<int>	0 – ∞	NIL	Maximal area of a hole to be filled
←	outRegion	Region&			Output region

Description

The operation extends a region to contain all pixels inside any of the region holes. Holes of a region are those connected areas of pixels **not** belonging to the region, that do not touch the boundary of the region frame.

Examples

FillRegionHoles *run on a sample region.*

Remarks

This filter is mostly used in **Blob Analysis Technique** please refer to our **Machine Vision Guide – Blob Analysis** article.

See Also

- RegionNumberOfHoles – Computes the number of holes in a region.

RegionBoundaries

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Removes interior pixels from a region.

Syntax

```
void avl::RegionBoundaries
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 avl::Region& outRegion
)
```

Parameters

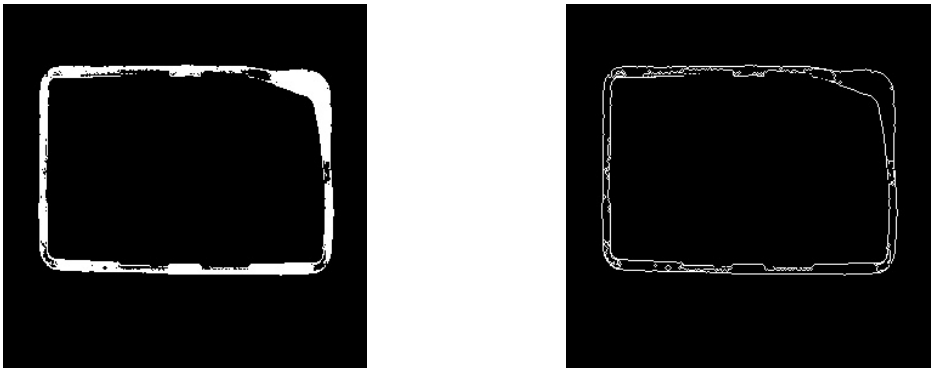
	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inConnectivity	RegionConnectivity::Type		Type of connectivity used for the region foreground
←	outRegion	Region&		Output region

Description

The operation removes all internal pixels from the region (thus leaving only the boundary pixels). The definition of *internal pixel* depends on the **inConnectivity** value:

- If **inConnectivity** is set to **Four directions**, internal pixels are those having neighbours in all four major directions (up, down, left, right) also contained in the region
- If **inConnectivity** is set to **Eight directions**, internal pixels are those having neighbours in all eight directions (four major + four diagonal) also contained in the region

Examples



***RegionBoundaries** run on a sample region.*

See Also

- RegionContours – Computes an array of closed paths corresponding to the contours of the input region.
- RegionInteriors – Removes boundary pixels from a region.

RegionConvexHull

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest convex region containing the input region.

Syntax

```
void avl::RegionConvexHull
(
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

The operation computes the smallest of all convex region containing the given one.

Examples

RegionConvexHull *run on a sample region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in RegionConvexHull.

See Also

- RegionConvexity – Computes the area of a region divided by area of its convex hull.
- PathConvexHull – Computes the smallest convex shape that contains the given path.

RegionConvexHull_AsPath

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest convex polygon containing the input region.

Syntax

```
void avl::RegionConvexHull_AsPath
(
 const avl::Region& inRegion,
 avl::Path& outConvexHull
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outConvexHull	Path&		

RegionInteriors

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Removes boundary pixels from a region.

Syntax

```
void avl::RegionInteriors
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inConnectivity	RegionConnectivity::Type		Type of connectivity used for the region foreground
←	outRegion	Region&		Output region

Description

The operation removes all boundary pixels from the region (thus leaving only the interior pixels). The definition of *boundary pixel* depends on the **inConnectivity** value:

- If **inConnectivity** is set to **Four directions**, boundary pixels are those having **at least one** of the neighbours in four major directions (up, down, left, right) **not** contained in the region
- If **inConnectivity** is set to **Eight directions**, boundary pixels are those having **at least one** of the neighbours in all eight directions (four major + four diagonal) **not** contained in the region

Examples

RegionInteriors *run on a sample region.*

Remarks

This filter is mostly used in **Blob Analysis Technique** please refer to our **Machine Vision Guide - Blob Analysis** article.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported connectivity type in RegionInteriors.

See Also

- RegionBoundaries - Removes interior pixels from a region.

RegionOuterBoundaries

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the top, right, bottom and left boundaries of the input region.

Syntax

```
void avl::RegionOuterBoundaries
(
 const avl::Region& inRegion,
 atl::Array< avl::Location >& outTopBoundary,
 atl::Array< avl::Location >& outRightBoundary,
 atl::Array< avl::Location >& outBottomBoundary,
 atl::Array< avl::Location >& outLeftBoundary
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outTopBoundary	Array< Location >&		
←	outRightBoundary	Array< Location >&		
←	outBottomBoundary	Array< Location >&		
←	outLeftBoundary	Array< Location >&		

RemoveBordersFromRegion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Removes from a region the pixels that lie very close to the region's frame.

Applications: Assures that the resulting region is not "touching" the borders.

Syntax

```
void avl::RemoveBordersFromRegion
(
 const avl::Region& inRegion,
 int inMarginX,
 int inMarginY,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inMarginX	int	0 – ∞		Horizontal margin from the region border
→	inMarginY	int	0 – ∞		Vertical margin from the region border
←	outRegion	Region&			Output region

RemoveRegionBlobs

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits a region into blobs, removes blobs not fulfilling the specified condition, and merges the rest back into one region.

Syntax

```
void avl::RemoveRegionBlobs
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 avl::RegionFeature::Type inFeature,
 atl::Optional<float> inMinimum,
 atl::Optional<float> inMaximum,
 bool inRemoveBoundaryBlobs,
 avl::Region& outRegion
)
```

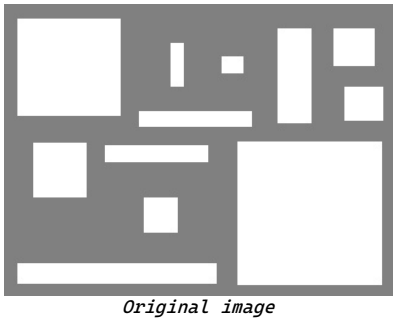
Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inConnectivity	RegionConnectivity::Type			Type of connectivity used for the region foreground
→	inFeature	RegionFeature::Type			Region feature value to be computed
→	inMinimum	Optional<float>	0.0 – ∞	1.0f	Minimal value of the considered feature
→	inMaximum	Optional<float>	0.0 – ∞	NIL	Maximal value of the considered feature
→	inRemoveBoundaryBlobs	bool		False	Flag indicating whether the blobs on border of the input region should be removed or not
←	outRegion	Region&			Output region

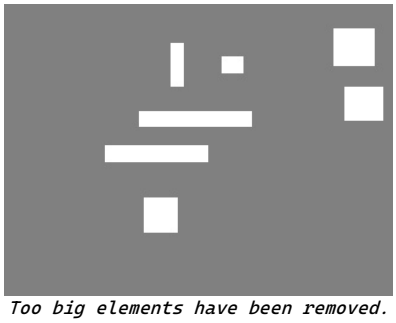
Description

This filter removes regions, which don't fulfill specific conditions given in **inMinimum** and **inMaximum** inputs. Both inputs are optional, which means that you don't have to set fixed limitations of your parameter's range. Classification can be based on different region features, for example area, convexity, mass center.

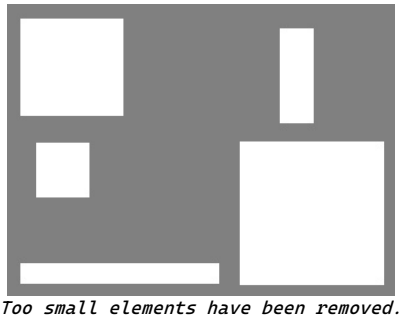
Examples



Original image



Too big elements have been removed.



Too small elements have been removed.

See Also

- ClassifyRegions – Splits an array of regions according to the selected feature and range.
- SplitRegionIntoBlobs – Splits a region into an array of regions corresponding to its connected components.
- RegionUnion_OfArray – Computes a region containing all the pixels that any of the input regions contains.

RemoveRegionBoundaryBlobs

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Removes all blobs intersecting a boundary of a given region.

Syntax

```
void avl::RemoveRegionBoundaryBlobs
(
 const avl::Region& inRegion,
 const avl::Region& inBorderRegion,
 avl::RegionConnectivity::Type inConnectivity,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inBorderRegion	const Region&		Region which boundary is used.
→	inConnectivity	RegionConnectivity::Type		Type of connectivity used for the region foreground
←	outRegion	Region&		Output region

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported connectivity type in RemoveRegionBoundaryBlobs.

SplitRegionIntoBlobs

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits a region into an array of regions corresponding to its connected components.

Applications: Segmentation of a region into individual objects when the objects do not touch each other.

Syntax

```
void avl::SplitRegionIntoBlobs
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 const int inMinBlobArea,
 atl::Optional<int> inMaxBlobArea,
 bool inRemoveBoundaryBlobs,
 atl::Array<avl::Region>& outBlobs
)
```

Parameters

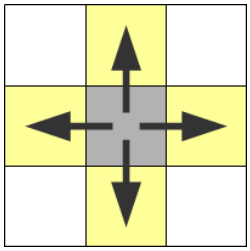
	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inConnectivity	RegionConnectivity::Type			Type of connectivity used for the region foreground
→	inMinBlobArea	const int	0 – ∞	1	Minimal area of a resulting blob
→	inMaxBlobArea	Optional<int>	0 – ∞	NIL	Maximal area of a resulting blob
→	inRemoveBoundaryBlobs	bool		False	Flag indicating whether the blobs on border of the input region should be removed or not
←	outBlobs	Array<Region>&			

Description

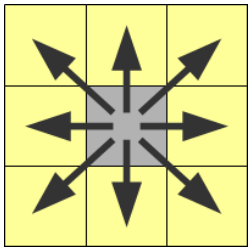
The operation computes an array of connected regions corresponding to the connected components of the input region pixels. Each region in the resulting array will have dimensions equal to those of the input region.

Resulting array will contain only regions which have area in range defined by inputs: **inMinBlobArea** and **inMaxBlobArea**.

Images below shows neighbor of the gray pixel in different **inConnectivity** selection.



inConnectivity.FourDirections



inConnectivity.EightDirections

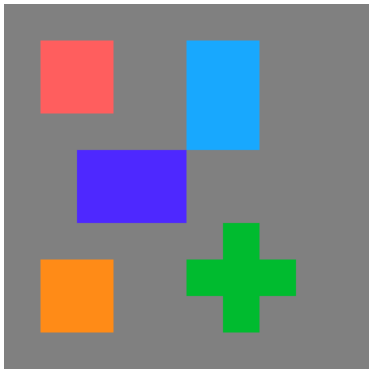
Hints

- In most cases this function works without any parametrization. Just pass a single region to the **inRegion** input.
- To reject small blobs, which are often caused by noise, increase **inMinBlobArea**.
- To reject big blobs, which sometimes appear due to some background pattern, define **inMaxBlobArea**.
- Set **inRemoveBoundaryBlobs** to ignore blobs of partially visible objects, touching the edges of the image.

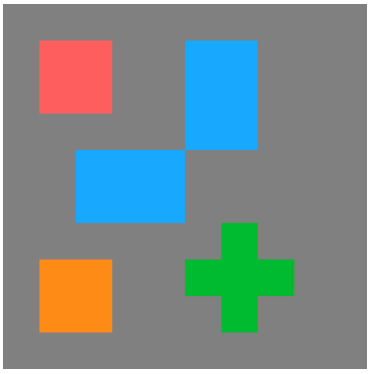
Examples

The image below show an input 10x10 pixels region.

Images below shows result of **SplitRegionIntoBlobs** filter with different **inConnectivity**.

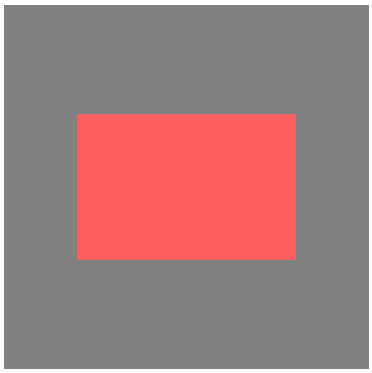


inConnectivity.FourDirections

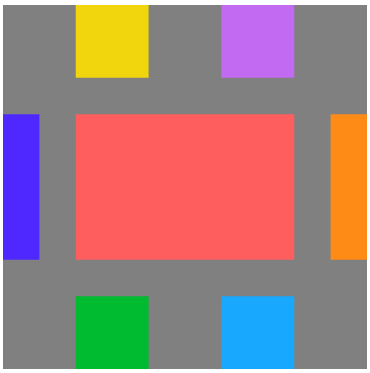


inConnectivity.EightDirections

Images below shows result of **SplitRegionIntoBlobs** filter with different **inRemoveBoundaryBlobs**.



inRemoveBoundaryBlobs = True



inRemoveBoundaryBlobs = False

Remarks

When **inRemoveBoundaryBlobs** is set to **True** all filters near the region boundary will be removed. The region boundary is described by region frame.

This filter is mostly used in **Blob Analysis Technique** please refer to our **Machine Vision Guide - Blob Analysis** article.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- SplitRegionIntoComponents - Splits a region into an array of regions. Operates by merging blobs in accordance to the inMaxDistance parameter.
- SplitRegionIntoMultipleCharacters - Splits the input region into an array of regions corresponding to individual characters.
- CropRegion - Creates a region from a rectangular fragment of another one.

SplitRegionIntoComponents

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits a region into an array of regions. Operates by merging blobs in accordance to the inMaxDistance parameter.

Syntax

```
void avl::SplitRegionIntoComponents
(
 const avl::Region& inRegion,
 atl::Optional<int> inMaxDistance,
 float inDistanceBalance,
 atl::Optional<float> inMaxJointDiameter,
 atl::Optional<int> inMaxJointWidth,
 atl::Optional<int> inMaxJointHeight,
 const int inMinComponentArea,
 atl::Optional<int> inMaxComponentArea,
 bool inRemoveBoundaryBlobs,
 atl::Array<avl::Region>& outComponents
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inMaxDistance	Optional<int>	0 – ∞	5	
→	inDistanceBalance	float	-1.0 – 1.0		Defines how much important the distance between regions in x coordinate is according to distance in y coordinate
→	inMaxJointDiameter	Optional<float>	0.0 – ∞	NIL	
→	inMaxJointWidth	Optional<int>	0 – ∞	NIL	
→	inMaxJointHeight	Optional<int>	0 – ∞	NIL	
→	inMinComponentArea	const int	0 – ∞	1	Minimal area of a resulting component
→	inMaxComponentArea	Optional<int>	0 – ∞	NIL	Maximal area of a resulting component
→	inRemoveBoundaryBlobs	bool		False	Flag indicating whether the blobs on border of the input region should be removed or not
←	outComponents	Array<Region>&			

Description

The filter splits the input region into blobs and iteratively joins some of them into bigger components. Only blobs that are distant from each other by at most **inMaxDistance** can be joined. The joining order is determined based on modified distance between two blobs, so the closest ones are joined first. This modified distance between two blobs is computed as follows:

1. The shortest segment connecting two blobs is computed.
2. The segment is scaled by

   $$0.5 \cdot (1 + inDistanceBalance)$$

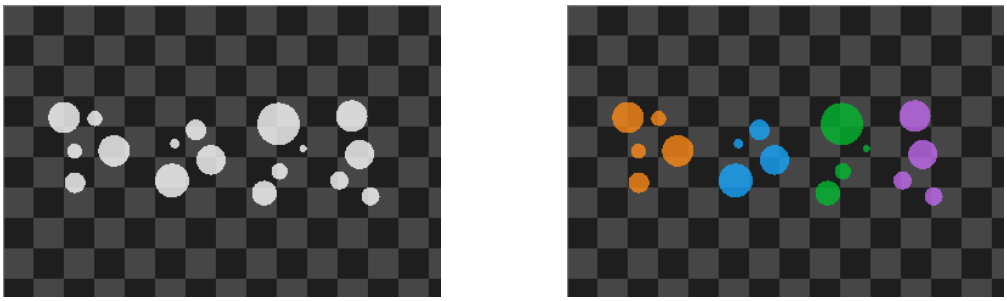
   along the X axis and by

   $$0.5 \cdot (1 - inDistanceBalance)$$

   along the Y axis.
3. Finally the length of the so scaled segment is computed.

Every region being a result of such blob joining has to satisfy conditions defined by **inMaxJointDiameter**, **inMaxJointWidth** and **inMaxJointHeight** parameters. Finally, only regions with appropriate area between **inMinComponentArea** and **inMaxComponentArea** are parts of the output component table.

Examples



***SplitRegionIntoComponents** used with **inMaxDistance** = 50.*

Remarks

This filter is mostly used in **Blob Analysis Technique** please refer to our **Machine Vision Guide - Blob Analysis** article.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

See Also

- SplitRegionIntoBlobs - Splits a region into an array of regions corresponding to its connected components.
- SplitRegionIntoExactlyNComponents - Splits a region into a fixed-size array of regions.

SplitRegionIntoExactlyNComponents

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Splits a region into a fixed-size array of regions.

Syntax

```
void avl::SplitRegionIntoExactlyNComponents
(
 const avl::Region& inRegion,
 int inComponentCount,
 atl::Optional<int> inMaxDistance,
 float inDistanceBalance,
 atl::Optional<float> inMaxJointDiameter,
 atl::Optional<int> inMaxJointWidth,
 atl::Optional<int> inMaxJointHeight,
 bool inRemoveBoundaryBlobs,
 atl::Conditional<atl::Array<avl::Region> >& outComponents
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inComponentCount	int	1 - ∞		
→	inMaxDistance	Optional<int>	0 - ∞	5	
→	inDistanceBalance	float	-1.0 - 1.0		Defines how much important the distance between regions in x coordinate is according to distance in y coordinate
→	inMaxJointDiameter	Optional<float>	0.0 - ∞	NIL	
→	inMaxJointWidth	Optional<int>	0 - ∞	NIL	
→	inMaxJointHeight	Optional<int>	0 - ∞	NIL	
→	inRemoveBoundaryBlobs	bool		False	Flag indicating whether the blobs on border of the input region should be removed or not
←	outComponents	Conditional<Array<Region> >&			

Description

The filter splits the input region into blobs and iteratively joins some of them into bigger components until only **inComponentCount** components remain. Only blobs that are distant from each other by at most **inMaxDistance** can be joined. The joining order is determined based on modified distance between two blobs, so the closest ones are joined first. This modified distance between two blobs is computed as follows:

1. The shortest segment connecting two blobs is computed.
2. The segment is scaled by

   $$0.5 \cdot (1 + inDistanceBalance)$$

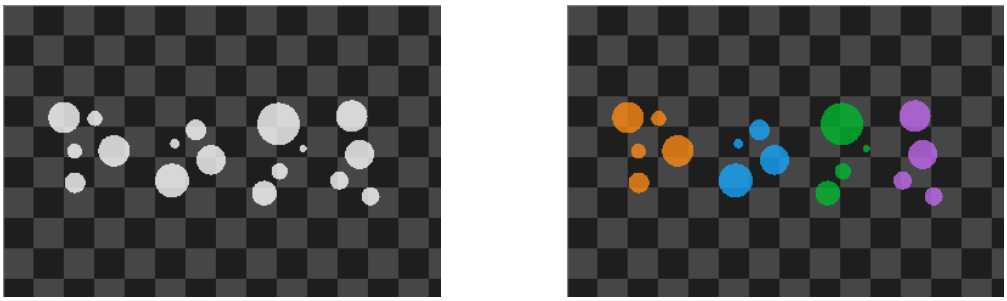
   along the X axis and by

   $$0.5 \cdot (1 - inDistanceBalance)$$

   along the Y axis.
3. Finally the length of the so scaled segment is computed.

Every region being a result of such blob joining has to satisfy conditions defined by **inMaxJointDiameter**, **inMaxJointWidth** and **inMaxJointHeight** parameters.

Examples



SplitRegionIntoExactlyNComponents *used with* ***inComponentCount*** *= 4.*

Remarks

This filter is mostly used in **Blob Analysis Technique** please refer to our **Machine Vision Guide - Blob Analysis** article.

See Also

- SplitRegionIntoBlobs - Splits a region into an array of regions corresponding to its connected components.
- SplitRegionIntoComponents - Splits a region into an array of regions. Operates by merging blobs in accordance to the inMaxDistance parameter.

FindDataMode_FixedCount

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the mode in a set of data values by looking for highest concentration of a fixed number of samples.

Applications: Can be used to determine a histogram maximum without actually creating the histogram.

Syntax

```
void avl::FindDataMode_FixedCount
(
 const atl::Array<float>& inValues,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 int inCount,
 atl::Optional<float> inCycle,
 float& outMode,
 float& outMiddle,
 float& outSpread
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			
→	inMinValue	Optional<float>		NIL	
→	inMaxValue	Optional<float>		NIL	
→	inCount	int	2 – ∞	3	
→	inCycle	Optional<float>		NIL	
←	outMode	float&			
←	outMiddle	float&			
←	outSpread	float&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array in FindDataMode_FixedCount.

FindDataMode_FixedSpread

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the mode in a set of data values by looking for highest number of samples withing the specified spread.

Applications: Can be used to determine a histogram maximum without actually creating the histogram.

Syntax

```
void avl::FindDataMode_FixedSpread
(
 const atl::Array<float>& inValues,
 float inSpread,
 atl::Optional<float> inCycle,
 float& outMode,
 float& outMiddle,
 int& outCount,
 float& outSpread
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			
→	inSpread	float	0.0 – ∞	2.0f	
→	inCycle	Optional<float>		NIL	
←	outMode	float&			
←	outMiddle	float&			
←	outCount	int&			
←	outSpread	float&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array in FindDataMode_FixedSpread.

FindDataMode_MeanShift

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the mode in a set of data values by iteratively computing its median.

Applications: Can be used to determine a histogram maximum without actually creating the histogram.

Syntax

```
void avl::FindDataMode_MeanShift
(
 const atl::Array<float>& inValues,
 int inIterationCount,
 float inSpread,
 float& outMode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			
→	inIterationCount	int	0 – 1000	1	
→	inSpread	float	0.0 – ∞	2.0f	
←	outMode	float&			

FindDensityMaxima_FixedCount

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds local density maxima in set of values by looking for the highest concentration of a fixed number of samples.

Applications: Can be used to determine histogram's local maxima without actually creating the histogram.

Syntax

```
void avl::FindDensityMaxima_FixedCount
(
 const atl::Array<float>& inValues,
 int inCount,
 atl::Optional<float> inMaxSpread,
 bool inAllowOverlapping,
 atl::Optional<float> inCycle,
 avl::DataModeFunction::Type inModeFunction,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<float>& outModes,
 atl::Array<float>& outSpreads
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			Data points array
→	inCount	int	2 – ∞	3	Number of points in a single window
→	inMaxSpread	Optional<float>		NIL	Maximum spread of points within a window
→	inAllowOverlapping	bool			If true all local maxima will be returned otherwise for each group of ranges that overlap a single mode will be returned (the middle of the group)
→	inCycle	Optional<float>		NIL	Length of the cycle if data is to be considered cyclically
→	inModeFunction	DataModeFunction::Type		Mean	Method of calculating the center of a data mode
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Helps to sieve out unnecessary points
←	outModes	Array<float>&			Computed data modes
←	outSpreads	Array<float>&			Spreads of windows that had a mode

Description

Find approximations of local density maxima in a data sample by looking for highest concentrations in a window with a fixed number of samples.

Overlapping windows (i.e. a series of windows with the same count and the same spread) can be returned as a single mode (the middle those windows) if **inAllowOverlapping** is set to false.

inMaxSpread and **inLocalBlindness** can be used to further filter out potentially unnecessary points in the output.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array in FindDensityMaxima_FixedCount.
DomainError	Unsupported mode function in FindDensityMaxima_FixedCount.

See Also

- FindDataMode_FixedCount – Finds the mode in a set of data values by looking for highest concentration of a fixed number of samples.
- FindDensityMaxima_FixedSpread – Finds local density maxima in a set of values by looking for the highest number of samples withing a range determined by the given spread.

FindDensityMaxima_FixedSpread

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds local density maxima in a set of values by looking for the highest number of samples withing a range determined by the given spread.

Applications: Can be used to determine histogram's local maxima without actually creating the histogram.

Syntax

```
void avl::FindDensityMaxima_FixedSpread
(
 const atl::Array<float>& inValues,
 float inSpread,
 int inMinCount,
 bool inAllowOverlapping,
 atl::Optional<float> inCycle,
 avl::DataModeFunction::Type inModeFunction,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<float>& outModes,
 atl::Array<int>& outCounts
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			Data points array
→	inSpread	float	0.0 – ∞	2.0f	Maximum spread of a single window
→	inMinCount	int	1 – ∞	1	Windows with a smaller count will not be considered
→	inAllowOverlapping	bool			If true all local maxima will be returned otherwise for each group of ranges that overlap only the one with the smallest real spread will be returned
→	inCycle	Optional<float>		NIL	Length of the cycle if data is to be considered cyclically
→	inModeFunction	DataModeFunction::Type		Mean	Method of calculating the center of a data mode
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Helps to sieve out unnecessary points
←	outModes	Array<float>&			Computed data modes
←	outCounts	Array<int>&			Sizes of windows that had a mode

Description

Find approximations of local density maxima in a data sample by looking for highest concentrations in a window with a bounded spread.

Overlapping windows (i.e. a series of windows with the same count) can be sieved if **inAllowOverlapping** is set to false. The sieving removes all modes that are shadowed by (i.e. are overlapping with) another mode with a smaller spread.

inMinCount and **inLocalBlindness** can be used to further filter out potentially unnecessary points in the output.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array in FindDensityMaxima_FixedSpread.

See Also

- FindDataMode_FixedSpread – Finds the mode in a set of data values by looking for highest number of samples withing the specified spread.
- FindDensityMaxima_FixedCount – Finds local density maxima in set of values by looking for the highest concentration of a fixed number of samples.

FindMatchingRegions_IoU

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds corresponding regions in two arrays based on IoU value.

Syntax

```
void avl::FindMatchingRegions_IoU
(
 const atl::Array<avl::Region>& inMasks,
 const atl::Array<int>& inMasksClasses,
 const atl::Array<avl::Region>& inPredicted,
 const atl::Array<int>& inPredictedClasses,
 double inThreshold,
 atl::Array<atl::Conditional<int> >& outMatchedIndexes,
 atl::Array<atl::Conditional<avl::Region>>& outMatchedRegions,
 atl::Array<atl::Conditional<double>>& outScores,
 atl::Array<atl::Conditional<double>>& diagCandidateScores
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMasks	const Array<Region>&			Original masks
→	inMasksClasses	const Array<int>&			
→	inPredicted	const Array<Region>&			Regions from the classifier
→	inPredictedClasses	const Array<int>&			
→	inThreshold	double	0.0D – 1.0D	0.5D	
←	outMatchedIndexes	Array<Conditional<int> >&			
←	outMatchedRegions	Array<Conditional<Region>>&			
←	outScores	Array<Conditional<double>>&			Returns scores of accepted regions
🔍	diagCandidateScores	Array<Conditional<double>>&			Returns best scores for regions

Errors

List of possible exceptions:

Error type	Description
DomainError	All regions in inMasks and inPredicted should have this same format.
DomainError	inMasks and inMasksClasses has different element count
DomainError	inPredicted and inPredictedClasses has different element count

RegionsIoU

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes intersection over union value for two regions.

Syntax

```
void avl::RegionsIoU
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 double& outIoT
)
```

Parameters

	Name	Type	Default	Description
→	inRegion1	const Region&		First input region
→	inRegion2	const Region&		Second input region
←	outIoT	double&		

Errors

List of possible exceptions:

Error type	Description
DomainError	inRegion1 has different frame dimensions than inRegion2 in RegionsIoU

TableOfConfusion_Basic

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes statistics from a confusion matrix for given TP, FP, TN, FN.

Syntax

```
void avl::TableOfConfusion_Basic
(
 atl::int64 inTruePositive,
 atl::int64 inFalsePositive,
 atl::int64 inTrueNegative,
 atl::int64 inFalseNegative,
 avl::ConfusionTable& outConfusionTable
)
```

Parameters

	Name	Type	Default	Description
→	inTruePositive	int64		
→	inFalsePositive	int64		
→	inTrueNegative	int64		
→	inFalseNegative	int64		
←	outConfusionTable	ConfusionTable&		

TableOfConfusion_BoolArray

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes statistics from a confusion matrix for an array of groundTruth and results.

Syntax

```
void avl::TableOfConfusion_BoolArray
(
 const atl::Array<bool>& inGroundTruth,
 const atl::Array<bool>& inResults,
 atl::int64& outTruePositive,
 atl::int64& outFalsePositive,
 atl::int64& outTrueNegative,
 atl::int64& outFalseNegative,
 avl::ConfusionTable& outConfusionTable
)
```

Parameters

	Name	Type	Default	Description
→	inGroundTruth	const Array<bool>&		
→	inResults	const Array<bool>&		
←	outTruePositive	int64&		
←	outFalsePositive	int64&		
←	outTrueNegative	int64&		
←	outFalseNegative	int64&		
←	outConfusionTable	ConfusionTable&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Array inGroundTruth is empty in TableOfConfusion_BoolArray.

TableOfConfusion_Histograms

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes confusion matrix based on two histograms and threshold value.

Syntax

```
void avl::TableOfConfusion_Histograms
(
 const avl::Histogram& inPositiveValues,
 const avl::Histogram& inNegativeValues,
 float inThreshold,
 avl::ConfusionTable& outConfusionTable
)
```

Parameters

	Name	Type	Default	Description
→	inPositiveValues	const Histogram&		Pixels values under binary classification mask
→	inNegativeValues	const Histogram&		Pixels values not covered by mask
→	inThreshold	float	128.0f	
←	outConfusionTable	ConfusionTable&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Histogram inNegativeValues is empty in TableOfConfusion_Histograms.
DomainError	Histogram inPositiveValues is empty in TableOfConfusion_Histograms.
DomainError	Histograms inPositiveValues and inNegativeValues has different domain in TableOfConfusion_Histograms.
DomainError	inThreshold is larger than domain end in TableOfConfusion_Histograms.
DomainError	inThreshold is smaller than domain start in TableOfConfusion_Histograms.

TableOfConfusion_Images

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes statistics from a confusion matrix for image of groundTruth and results.

Syntax

```
void avl::TableOfConfusion_Images
(
 const avl::Image& inImageGroundTruth,
 const avl::Image& inImageResults,
 int inThreshold,
 atl::int64& outTruePositive,
 atl::int64& outFalsePositive,
 atl::int64& outTrueNegative,
 atl::int64& outFalseNegative,
 avl::ConfusionTable& outConfusionTable
)
```

Parameters

	Name	Type	Default	Description
→	inImageGroundTruth	const Image&		Binary image of ground truth
→	inImageResults	const Image&		
→	inThreshold	int	0	
←	outTruePositive	int64&		
←	outFalsePositive	int64&		
←	outTrueNegative	int64&		
←	outFalseNegative	int64&		
←	outConfusionTable	ConfusionTable&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Height of inImageGroundTruth isn't correspond to inImageResults's height in TableOfConfusion_Images.
DomainError	Image inGroundTruthImage is empty in TableOfConfusion_Images.
DomainError	Width of inImageGroundTruth isn't correspond to inImageResults's width in TableOfConfusion_Images.

Average

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the average of an array of real numbers. The array must be not empty.

Syntax

```
void avl::Average
(
 const atl::Array<float>& inValues,
 float& outAverage
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
←	outAverage	float&		

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in Average.

Also in AVL Lite

Median

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the median of an array of real numbers. The array must be not empty. Optional weights, when supplied, must be positive.

Syntax

```
void avl::Median
(
 const atl::Array<float>& inValues,
 const atl::Optional<const atl::Array<float>&>& inWeights,
 float& outMedian,
 atl::Array<float>& outValues = atl::Dummy<atl::Array<float>>()
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
→	inWeights	const Optional<const Array<float>&>&	NIL	
←	outMedian	float&		
←	outValues	Array<float>&	Dummy<Array<float>> ()	

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in Median.

Also in AVL Lite

Median_InPlace

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the median of an array of real numbers. Modifies the input array for the purpose of speed.

Syntax

```
void avl::Median_InPlace
(
 atl::Array<float>& ioValues,
 float& outMedian
)
```

Parameters

	Name	Type	Default	Description
↔	ioValues	Array<float>&		
←	outMedian	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in Median_InPlace.

NthValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes n-th smallest value in an array (0-indexed). The array must be not empty.

Syntax

```
void avl::NthValue
(
 const atl::Array<float>& inValues,
 int inN,
 float& outNthValue
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
→	inN	int		
←	outNthValue	float&		

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Selected N exceed the array index range in NthValue.

PearsonCorrelation

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes Pearson product-moment correlation coefficient. The array must be not empty.

Syntax

```
void avl::PearsonCorrelation
(
 const atl::Array<float>& inValues1,
 const atl::Array<float>& inValues2,
 float inMinStdDev,
 float& outCorrelation
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues1	const Array<float>&			Array of values of the first variable
→	inValues2	const Array<float>&			Array of values of the second variable
→	inMinStdDev	float	0.0 – ∞	0.001f	Minimum value of standard deviation for correlation to be non-zero
←	outCorrelation	float&			Computed correlation coefficient between two variables

Hints

- Make sure that the standard deviation of both input arrays is non-zero.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot compute the value of PearsonCorrelation. The standard deviation of some set of input values is equal to zero.
DomainError	Empty array on input in PearsonCorrelation.
DomainError	Inconsistent size of arrays in PearsonCorrelation.

Also in AVL Lite

PearsonCorrelation_Weighted

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes Pearson product-moment correlation coefficient with weights.

Syntax

```
void avl::PearsonCorrelation_Weighted
(
 const atl::Array<float>& inValues1,
 const atl::Array<float>& inValues2,
 const atl::Array<float>& inWeights,
 float inMinStdDev,
 float& outCorrelation
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues1	const Array<float>&			Array of values of the first variable
→	inValues2	const Array<float>&			Array of values of the second variable
→	inWeights	const Array<float>&			Weights corresponding to the elements of 'inValues1' and 'inValues2'
→	inMinStdDev	float	0.0 – ∞	0.001f	Minimum value of standard deviation for correlation to be non-zero
←	outCorrelation	float&			Computed correlation coefficient between two variables

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot compute the value of PearsonCorrelation_Weighted. The standard deviation of some set of input values is equal to zero.
DomainError	Empty array on input in PearsonCorrelation_Weighted.
DomainError	Inconsistent size of arrays in PearsonCorrelation_Weighted.

Quantile

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the specified quantile of an array of real numbers. The array must be not empty.

Syntax

```
void avl::Quantile
(
 const atl::Array<float>& inValues,
 float inQuantilePoint,
 float& outQuantileValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			
→	inQuantilePoint	float	0.0 – 1.0	0.5f	
←	outQuantileValue	float&			

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in Quantile.

StandardDeviation

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the standard deviation of an array of real numbers. The array must be not empty.

Syntax

```
void avl::StandardDeviation
(
 const atl::Array<float>& inValues,
 const bool inUseSampleFormula,
 float& outStandardDeviation
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
→	inUseSampleFormula	const bool		
←	outStandardDeviation	float&		

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array on input in StandardDeviation.

Variance

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes the variance of an array of real numbers. The array must be not empty.

Syntax

```
void avl::Variance
(
 const atl::Array<float>& inValues,
 const bool inUseSampleFormula,
 float& outVariance
)
```

Parameters

	Name	Type	Default	Description
→	inValues	const Array<float>&		
→	inUseSampleFormula	const bool		
←	outVariance	float&		

Hints

- If the input array is not guaranteed to be non-empty, precede this filter with SkipEmptyArray.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot calculate Variance of sample of size 1. Correct input data, or use Variance filter for population.

94. Surface Fitting

Table of content:

- FitCircleToSurfaceHole
- FitPlaneToSurface
- FitPlaneToSurface_M

FitCircleToSurfaceHole

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Fits a circle to a hole in a surface plane.

Syntax

```
void avl::FitCircleToSurfaceHole
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::MEstimator::Type inPlaneOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 avl::CircleFittingMethod::Type inCircleFittingMethod,
 atl::Optional<avl::MEstimator::Type> inCircleOutlierSuppression,
 atl::Conditional<avl::Circle3D>& outCircle3D,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inPlaneOutlierSuppression	MEstimator::Type			Selects a method for ignoring points not lying on the fitted plane
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialPlane	Optional<const Plane3D&>		NIL	Initial approximation of a plane (if available)
→	inCircleFittingMethod	CircleFittingMethod::Type			Select a method for fitting a circle to a set of points
→	inCircleOutlierSuppression	Optional<MEstimator::Type>		NIL	Selects a method for ignoring points not lying on the fitted circle
←	outCircle3D	Conditional<Circle3D>&			Circle fitted to a surface hole
←	outPlane	Plane3D&			Plane fitted to the surface points
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the computed plane
←	outDistances	Optional<Array<float>&>		NIL	Distances of the input surface points to a resulting plane
←	outSignedDistanceSum	Optional<float&>		NIL	Sum of signed distances of the input surface points to a resulting plane
←	outDistanceSum	Optional<float&>		NIL	Sum of distances of the input surface points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>		NIL	Squared distances of the input surface points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>		NIL	Sum of squared distances of the input surface points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**, **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in FitCircleToSurfaceHole.

FitPlaneToSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points of the input surface with a plane using the Least Squares method.

Syntax

```
void avl::FitPlaneToSurface
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outPlane	Plane3D&		Fitted plane
←	outDistances	Optional<Array<float>&>	NIL	Distances of the input surface points to a resulting plane
←	outSignedDistanceSum	Optional<float&>	NIL	Sum of signed distances of the input surface points to a resulting plane
←	outDistanceSum	Optional<float&>	NIL	Sum of distances of the input surface points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>	NIL	Squared distances of the input surface points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>	NIL	Sum of squared distances of the input surface points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No points to fit the plane to in FitPlaneToSurface.
DomainError	Region of interest exceeds an input surface in FitPlaneToSurface.

FitPlaneToSurface_M

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Approximates points of the input surface with a plane using selected M-estimator for outlier suppression.

Applications: Finding a locally optimal plane. Good enough when the number of outliers is small.

Syntax

```
void avl::FitPlaneToSurface_M
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inOutlierSuppression	MEstimator::Type			Selects a method for ignoring points being much different from the rest
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialPlane	Optional<const Plane3D&>		NIL	Initial approximation (if available)
←	outPlane	Plane3D&			Fitted plane
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the computed plane
←	outDistances	Optional<Array<float>&>		NIL	Distances of the input points to a resulting plane
←	outSignedDistanceSum	Optional<float&>		NIL	Sum of signed distances of the input points to a resulting plane
←	outDistanceSum	Optional<float&>		NIL	Sum of distances of the input points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>		NIL	Squared distances of the input points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>		NIL	Sum of squared distances of the input points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**, **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No points to fit the plane to in FitPlaneToSurface_M.
DomainError	Region of interest exceeds an input surface in FitPlaneToSurface_M.

95. Format

Table of content:

- FormatLocationToString
- FormatPoint2DToString
- FormatPoint3DToString

FormatLocationToString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a location to a string of format "(X, Y)".

Syntax

```
void avl::FormatLocationToString
(
 const avl::Location& inLocation,
 const int inDigitCount,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 const int inSystemBase,
 const bool inPrintBrackets,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLocation	const Location&			
→	inDigitCount	const int	0 – ∞		How many characters the output coordinate should have at least
→	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
→	inForceSignPrinting	const bool		False	Forces printing the signs of the coordinates even if the number is positive
→	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
→	inSystemBase	const int	2 – 16	10	The base of the numeral system
→	inPrintBrackets	const bool		True	Determines whether the brackets should be printed or not
←	outString	String&			

FormatPoint2DToString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a 2D point to a string of format "(X, Y)".

Syntax

```
void avl::FormatPoint2DToString
(
 const avl::Point2D& inPoint,
 const int inIntegerDigitCount,
 const int inFractionalDigitCount,
 const atl::String& inDecimalMark,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 const bool inPrintBrackets,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			
→	inIntegerDigitCount	const int	0 – ∞		How many characters the integer part of the coordinates should have at least
→	inFractionalDigitCount	const int	0 – 100	3	How many characters the fractional part of the coordinates should have
→	inDecimalMark	const String&		\".\"	The symbol used to separate the integer part from the fractional part of the coordinates
→	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
→	inForceSignPrinting	const bool		False	Forces printing the signs of the numbers even if the number is positive
→	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
→	inPrintBrackets	const bool		True	Determines whether the brackets should be printed or not
←	outString	String&			

FormatPoint3DToString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a 3D point to a string of format "(X, Y, Z)".

Syntax

```
void avl::FormatPoint3DToString
(
 const avl::Point3D& inPoint,
 const int inIntegerDigitCount,
 const int inFractionalDigitCount,
 const atl::String& inDecimalMark,
 const atl::String& inTrailingCharacter,
 const bool inForceSignPrinting,
 const atl::String& inSuffix,
 const bool inPrintBrackets,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point3D&			
→	inIntegerDigitCount	const int	0 – ∞		How many characters the integer part of the coordinates should have at least
→	inFractionalDigitCount	const int	0 – 100	3	How many characters the fractional part of the coordinates should have
→	inDecimalMark	const String&		\".\"	The symbol used to separate the integer part from the fractional part of the coordinates
→	inTrailingCharacter	const String&		\"0\"	Defines the trailing character
→	inForceSignPrinting	const bool		False	Forces printing the signs of the numbers even if the number is positive
→	inSuffix	const String&		\"\"	Defines a suffix. Generally it is an unit of value (e.g. mm)
→	inPrintBrackets	const bool		True	Determines whether the brackets should be printed or not
←	outString	String&			

96. Fourier Analysis

Table of content:

- FourierTransform
- FrequencyDomain_FilterFrequencies
- FrequencyDomain_ModulusImage
- FrequencyDomain_PhaseImage
- InverseFourierTransform

FourierTransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms an image into frequency domain using Fourier transformation.

Syntax

```
void avl::FourierTransform
(
 const avl::Image& inSpatialDomainImage,
 avl::Image& outFrequencyDomainImage
)
```

Parameters

	Name	Type	Default	Description
→	inSpatialDomainImage	const Image&		
←	outFrequencyDomainImage	Image&		

Requirements

For input **inSpatialDomainImage** only pixel formats are supported: 1×uint8, 1×int8, 1×uint16, 1×int16, 1×int32, 1×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect input image depth in FourierTransform.
DomainError	Not supported inSpatialDomainImage pixel format in FourierTransform. Supported formats: 1xUInt8, 1xInt8, 1xUInt16, 1xInt16, 1xInt32, 1xReal.

FrequencyDomain_FilterFrequencies

Header: AVL.h
Namespace: avl
Module: FoundationPro

Filters the frequencies in a frequency domain image suppressing the elements of too low or too high frequency.

Syntax

```
void avl::FrequencyDomain_FilterFrequencies
(
 const avl::Image& inFrequencyDomainImage,
 const atl::Optional<float>& inMinFrequency,
 const atl::Optional<float>& inMaxFrequency,
 avl::Image& outFrequencyDomainImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inFrequencyDomainImage	const Image&			Input image in frequency domain
→	inMinFrequency	const Optional<float>&	0.0 – ∞	NIL	Minimum frequency that will be kept
→	inMaxFrequency	const Optional<float>&	0.0 – ∞	NIL	Maximum frequency that will be kept
←	outFrequencyDomainImage	Image&			Filtered image in frequency domain

Requirements

For input **inFrequencyDomainImage** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inFrequencyDomainImage pixel format in FrequencyDomain_FilterFrequencies. Supported formats: 2xReal.

FrequencyDomain_ModulusImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the modulus of each frequency domain image pixel.

Syntax

```
void avl::FrequencyDomain_ModulusImage
(
 const avl::Image& inFrequencyDomainImage,
 avl::Image& outModulusImage
)
```

Parameters

	Name	Type	Default	Description
→	inFrequencyDomainImage	const Image&		
←	outModulusImage	Image&		

Requirements

For input **inFrequencyDomainImage** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inFrequencyDomainImage pixel format in FrequencyDomain_ModulusImage. Supported formats: 2xReal.

FrequencyDomain_PhaseImage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the phase of each frequency domain image pixel.

Syntax

```
void avl::FrequencyDomain_PhaseImage
(
 const avl::Image& inFrequencyDomainImage,
 avl::Image& outPhaseImage
)
```

Parameters

	Name	Type	Default	Description
→	inFrequencyDomainImage	const Image&		
←	outPhaseImage	Image&		

Requirements

For input **inFrequencyDomainImage** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inFrequencyDomainImage pixel format in FrequencyDomain_PhaseImage. Supported formats: 2xReal.

InverseFourierTransform

Header: AVL.h
Namespace: avl
Module: FoundationPro

Transforms an image in frequency domain back to spatial domain using inverse Fourier transformation.

Syntax

```
void avl::InverseFourierTransform
(
 const avl::Image& inFrequencyDomainImage,
 avl::Image& outSpatialDomainImage
)
```

Parameters

	Name	Type	Default	Description
→	inFrequencyDomainImage	const Image&		
←	outSpatialDomainImage	Image&		

Requirements

For input **inFrequencyDomainImage** only pixel formats are supported: 2×real.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inFrequencyDomainImage pixel format in InverseFourierTransform. Supported formats: 2xReal.

97. FTP

Table of content:

- Ftp_ReceiveFile
- Ftp_ReceiveImage
- Ftp_ReceiveString
- Ftp_SendFile
- Ftp_SendImage
- Ftp_SendString

Ftp_ReceiveFile

Header: AVL.h
Namespace: avl
Module: FoundationLite

Downloads a file from a remote server using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_ReceiveFile
(
 const atl::File& inFilePath,
 const atl::String& inHostName,
 const atl::String& inFtpFilePath,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inFilePath	const File&			Location of the file on a remote server.
➡	inHostName	const String&		\"ftp://\"	URL address of the remote server.
➡	inFtpFilePath	const String&			Location of the file on a remote server.
➡	inUsername	Optional<const String&>		NIL	User name needed to log in.
➡	inPassword	Optional<const String&>		NIL	Password associated with a user name.
➡	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
➡	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
➡	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
➡	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty ftp file path on input in Ftp_ReceiveFile
DomainError	Empty host name on input in Ftp_ReceiveFile
DomainError	Empty path on input in Ftp_ReceiveFile

Also in AVL Lite

Ftp_ReceiveImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Downloads an image from a remote server using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_ReceiveImage
(
 const atl::String& inHostName,
 const atl::String& inFtpFilePath,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 bool inLoadAlphaChannel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHostName	const String&		\"ftp://\"	URL address of the remote server.
→	inFtpFilePath	const String&			Location of the file on a remote server.
→	inUsername	Optional<const String&>		NIL	User name needed to log in.
→	inPassword	Optional<const String&>		NIL	Password associated with a user name.
→	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
→	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
→	inLoadAlphaChannel	bool			Whether to load the alpha channel (if exists) as an additional image channel.
←	outImage	Image&			Image downloaded from the remote server.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty ftp file path on input in Ftp_ReceiveImage
DomainError	Empty host name on input in Ftp_ReceiveImage

Ftp_ReceiveString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Downloads a text string from a remote server using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_ReceiveString
(
 const atl::String& inHostName,
 const atl::String& inFtpFilePath,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::String& outText
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHostName	const String&		\"ftp://\"	URL address of the remote server.
→	inFtpFilePath	const String&			Location of the file on a remote server.
→	inUsername	Optional<const String&>		NIL	User name needed to log in.
→	inPassword	Optional<const String&>		NIL	Password associated with a user name.
→	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
→	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outText	String&			Text read from a remote server.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty ftp file path on input in Ftp_ReceiveString
DomainError	Empty host name on input in Ftp_ReceiveString

Ftp_SendFile

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a file to a remote server using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_SendFile
(
 const atl::File& inFilePath,
 const atl::String& inHostName,
 const atl::String& inDestinationFileName,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile
)
```

Parameters

	Name	Type	Range	Default	Description
→	inFilePath	const File&			Path to a file stored on the local drive.
→	inHostName	const String&		\"ftp://\"	URL address of the remote server.
→	inDestinationFileName	const String&			Path where a file should be saved on a remote server.
→	inUsername	Optional<const String&>		NIL	User name needed to log in.
→	inPassword	Optional<const String&>		NIL	Password associated with a user name.
→	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
→	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty destination file name on input in Ftp_SendFile
DomainError	Empty file path on input in Ftp_SendFile
DomainError	Empty host name on input in Ftp_SendFile

Ftp_SendImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends an image to a remote server using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_SendImage
(
 const avl::Image& inImage,
 atl::Optional<avl::ImageFileFormat::Type> inImageFileFormat,
 const atl::String& inHostName,
 const atl::String& inDestinationFileName,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inImage	const Image&			Image to send.
➡	inImageFileFormat	Optional<ImageFileFormat::Type>		NIL	If Nil the format will be chosen on the basis of extension.
➡	inHostName	const String&		\"ftp://\"	URL address of the remote server.
➡	inDestinationFileName	const String&			Path where an image file should be saved on a remote server.
➡	inUsername	Optional<const String&>		NIL	User name needed to log in.
➡	inPassword	Optional<const String&>		NIL	Password associated with a user name.
➡	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
➡	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
➡	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
➡	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty destination file name on input in Ftp_SendImage
DomainError	Empty host name on input in Ftp_SendImage

Ftp_SendString

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a string to a remote serve using FTP (File Transfer Protocol).

Syntax

```
void avl::Ftp_SendString
(
 const atl::String& inText,
 const atl::String& inHostName,
 const atl::String& inDestinationFileName,
 atl::Optional<const atl::String&> inUsername,
 atl::Optional<const atl::String&> inPassword,
 bool inUsePassiveMode,
 atl::Optional<int> inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inText	const String&			Text to send.
➡	inHostName	const String&		\"ftp://\"	URL address of the remote server.
➡	inDestinationFileName	const String&			Path where a text file should be saved on a remote server.
➡	inUsername	Optional<const String&>		NIL	User name needed to log in.
➡	inPassword	Optional<const String&>		NIL	Password associated with a user name.
➡	inUsePassiveMode	bool			Protocol communication mode. May be necessary when using a firewall.
➡	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
➡	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
➡	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty destination file name on input in Ftp_SendString
DomainError	Empty host name on input in Ftp_SendString

98. Datacodes

Table of content:

GenerateDatamatrixCode

Header: AVL.h
Namespace: avl
Module: Datacodes

Generates datamatrix code

Syntax

```
void avl::GenerateDatamatrixCode
(
 const atl::String& inText,
 int inScaleFactor,
 int inQuietZoneSize,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inText	const String&			Text to generate
→	inScaleFactor	int	1 – 10	4	Result image scale factor
→	inQuietZoneSize	int	0 – ∞	2	Quiet zone measured in module size
←	outImage	Image&			Output image

ReadMultipleCodes_IK

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads multiple codes in the input image.

Applications: An older, but the most comprehensive Zebra tool for reading all types of codes.

Syntax

```
void avl::ReadMultipleCodes_IK
(
 ImageKit_State& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 avl::CodeInverse1D::Type inInverse,
 atl::Optional<int> inTimeout,
 const avl::CodeDetectionParameters& inDetectionParameters,
 const avl::ManyCodeSettings& inManyCodeSettings,
 atl::Optional<const atl::File&> inConfigFile,

ReadMultipleCodes_IK_Binary

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads multiple codes in the input image; returns binary data.

Applications: Use this tool when you need access to the raw barcode content.

Syntax

```
void avl::ReadMultipleCodes_IK_Binary
(
 ImageKit_State& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 avl::CodeInverse1D::Type inInverse,
 atl::Optional<int> inTimeout,
 const avl::CodeDetectionParameters& inDetectionParameters,
 const avl::ManyCodeSettings& inManyCodeSettings,
 atl::Optional<const atl::File&> inConfigFile,
 bool inEnableCode39,

ReadMultipleCodes_Z

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads multiple 1D barcodes and PDF417 codes.

Applications: High-speed barcode reading with simple configuration.

Syntax

```
void avl::ReadMultipleCodes_Z
(
 ZCode_State& ioState,
 const avl::Image& inImage,
 const atl::Optional<atl::File>& inLoadConfigFile,
 const atl::Optional<atl::File>& inSaveConfigFile,
 atl::Optional<int> inTimeout,
 atl::Optional<int> inThreadCount,
 atl::Optional<int> inMaxCodeCount,
 bool inIssueIdenticalSymbols,
 const avl::Code1DSettings& inCode1DSettings,
 bool inEnablePDF417,
 bool inEnableCode128,
 bool inEnableCode39,
 bool inEnableCode93,
 bool inEnableInterleaved2of5,
 bool inEnableNoRead,
 bool inEnableQualityMetrics,
 atl::Array<avl::ZResult>& outResult,
 atl::Array<avl::ZQualityMetrics>& outQualityMetrics,
 atl::Array<avl::ZNoReadResult>& outNoReadResult
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ZCode_State&			Object used to maintain state of the function.
→	inImage	const Image&			Input image
→	inLoadConfigFile	const Optional<File>&		NIL	Configuration file to be loaded in .bin format. Used to restore previously saved settings - can overwrite other parameters.
→	inSaveConfigFile	const Optional<File>&		NIL	Path to save configuration file in .bin format. Used to save current settings for future use.
→	inTimeout	Optional<int>	1 - ∞	NIL	Processing timeout in ms
→	inThreadCount	Optional<int>	1 - 31	NIL	Number of processing threads
→	inMaxCodeCount	Optional<int>	1 - ∞	NIL	Maximum number of codes
→	inIssueIdenticalSymbols	bool		True	Issue identical symbols
→	inCode1DSettings	const Code1DSettings&			Code1D settings
→	inEnablePDF417	bool		True	
→	inEnableCode128	bool		True	
→	inEnableCode39	bool		False	
→	inEnableCode93	bool		False	
→	inEnableInterleaved2of5	bool		False	
→	inEnableNoRead	bool		False	Enable return of the no read results
→	inEnableQualityMetrics	bool		False	Enable return of quality metrics
←	outResult	Array<ZResult>&			Decode results
←	outQualityMetrics	Array<ZQualityMetrics>&			Quality metrics of decoded codes
←	outNoReadResult	Array<ZNoReadResult>&			No read result - code outline with the reason why it was not decoded

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	ReadMultipleCodes_Z is not supported on this platform.
DomainError	Not supported inImage pixel format in ReadMultipleCodes_Z. Supported formats: UInt8.

ReadMultipleDataCodes

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads multiple data codes (1D and 2D).

Applications: The main tool for reading both linear and matrix codes (Data Matrix, QR Code), including DPM.

Syntax

```
void avl::ReadMultipleDataCodes
(
 avl::ReadDataCodes_State& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 atl::Optional<const avl::MatrixSymbologies&> inMatrixSymbologies,
 atl::Optional<const avl::LinearSymbologies&> inLinearSymbologies,
 const avl::DataCodeDetectorParams& inDetectorParams,
 const avl::MatrixCodeParams& inMatrixCodeParams,
 const avl::DpmParams& inDpmParams,
 const avl::LinearCodeParams& inLinearCodeParams,
 bool inComputeScores,
 int inMaxCodeCount,
 bool inAllowMultipleScales,
 atl::Array<avl::DataCode>& outDataCodes,
 atl::Array<avl::Path>& outCandidates,
 atl::Optional<avl::Rectangle2D&> outAlignedRoi = atl::NIL,
 atl::Array<avl::DataCode>& outNoReads = atl::Dummy<atl::Array<avl::DataCode>>()
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ReadDataCodes_State&			Object used to maintain state of the function.
→	inImage	const Image&			Input image
→	inRoi	Optional<const Rectangle2D&>		NIL	Region of interest
→	inRoiAlignment	Optional<const CoordinateSystem2D&>		NIL	Coordinate system for the region of interest
→	inMatrixSymbologies	Optional<const MatrixSymbologies&>		NIL	Specifies which matrix symbologies the filter should try to read
→	inLinearSymbologies	Optional<const LinearSymbologies&>		NIL	Specifies which linear symbologies the filter should try to read
→	inDetectorParams	const DataCodeDetectorParams&			Parameters of the code detection algorithm, common for linear and matrix codes
→	inMatrixCodeParams	const MatrixCodeParams&			Parameters specific to matrix (2D) codes
→	inDpmParams	const DpmParams&			Parameters specific to direct part marking codes
→	inLinearCodeParams	const LinearCodeParams&			Parameters specific to linear (1D) codes
→	inComputeScores	bool			Enables computing of confidence scores (slower)
→	inMaxCodeCount	int	0 – ∞	1000	Maximum number of codes in one image
→	inAllowMultipleScales	bool		False	Specifies whether to continue search for codes at a higher resolution even when some codes have already been found at a lower resolution
←	outDataCodes	Array<DataCode>&			List of codes that have been correctly detected and decoded
←	outCandidates	Array<Path>&			Diagnostic information about detection results
←	outAlignedRoi	Optional<Rectangle2D&>		NIL	Input ROI after transformation (in the image coordinates)
←	outNoReads	Array<DataCode>&		Dummy<Array<DataCode>>()	List of codes that have been detected but not decoded

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRoi**.

Read more about Optional Outputs.

Description

The filter locates and decodes data codes (Data Matrix, QR Codes and linear barcodes) in an image within a given region (**inRoi**).

Groups of parameters

The tool's default parameters are selected for reading of high- and medium-quality codes at a good speed. If you need to achieve a higher speed, or read damaged or distorted codes, then some parameters may need to be adjusted. There are three main groups:

1. **inDetectorParams** – parameters of the code detector, common for 1D and 2D codes.
2. **inMatrixCodeParams** – parameters related to 2D code reading (Data Matrix and QR Code).
3. **inLinearCodeParams** – parameters related to 1D code reading (Code 128, EAN/UPC etc.).

Symbology selection

The first choice, and one that you must always make, is to select the code symbologies. Use **inMatrixSymbologies** for reading Data Matrix or QR Codes. Use **inLinearSymbologies** to read 1D types (Code 128, EAN/UPC etc.).

To assure the maximum possible performance, always select only those symbologies that you do need.

NOTE: If you enable one of these sections but leave all the options set to "False", the tool will still perform code detection (1D or 2D) but will skip the decoding phase. It may be useful for testing detector's execution time but should not be used at production.

Detection methods

The most important detector's setting is the detection algorithm, **inDetectorParams.DetectionMethod**. The tool offers three options:

	Finder Edges (default)	**Finder Pattern (basic)**	**Dot Grid (advanced)**
Where it looks?			How it works?	Looks for the edges of the L-shaped pattern. Uses a robust line segment detector internally.	It is a simple method based on blob analysis. Uses dynamic image thresholding to extract the code.	Ignores the finder and timing patterns altogether. Instead, directly recognizes the grid-like structure of the code.
When to use it?	This method is fast and effective even in challenging conditions, including DPM (direct part marking) but may be confused by additional lines appearing near the code. You can fine-tune it with **FinderTradeoff** and **EdgeTracker parameters.**	This method works well only on clearly printed codes with a correct quiet zone. May also handle some dot-codes when setting the **inDetectorParams.DotSize** properly.	This method can detect codes with highly damaged finder and timing patterns. Works best with dot-printed codes, but can work with fully-printed codes when **inDetectorParams.DotSize** is set to "Full".
Works with 1D?	Yes.	Sometimes.	No.

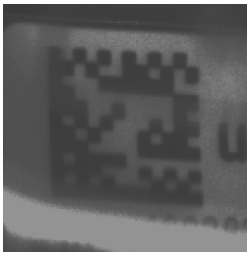
Pyramid strategy

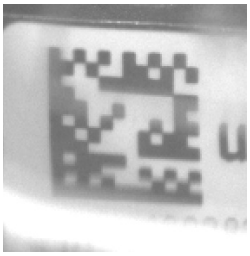
The tool tries to detect codes at different scale levels. It investigates images at different resolutions, starting with the lowest resolution. If it finds a sufficient number of codes at one level, it may skip looking further, thus achieving shorter execution time. If there are no codes in the input image, it will always scan all the levels, resulting in the highest execution time. For this reason, it is very important to set **inMatrixCodeParams.MinModuleSize** and/or **inLinearCodeParams.MinThinBarSize** precisely – setting it too low may significantly increase the tool's execution time.

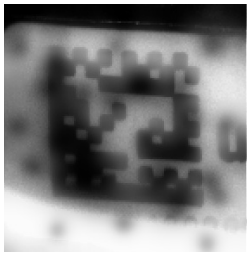
NOTE: If you experience instable execution times, for example, switching between 10 ms and 20 ms, it may indicate that for some images the tool finds a code at a higher level, while for some others it has to process the higher resolution too. For that reason, we also recommend testing time performance on the ReadMultipleDataCodes tool, with **inMaxCodeCount**=1000 and **inAllowMultipleScales**=True. This will assure that no early exit happens, and the execution time will be the maximum of what we may expect with the given settings.

Finder Tradeoff ("FinderEdges" only)

When using the "FinderEdges" method, you should be aware that there is a tradeoff between the ability of the tool to detect rugged (uneven, noised, or dot printed) edges and the ability to detect low contrast edges (or ones neighboring with a very narrow Quite Zone). The default setting is "Balanced". However, if you expect the edges of your code to be relatively straight and clean, but less strong, you may want to change it to "Sensitive". On the other hand, if the edges of the code are highly jagged or the surrounding is noisy, it may be better to choose "Robust". You may also set it to "Auto" and it will test several possibilities at the cost of much higher execution time.

Use "Sensitive"	Use "Balanced"	Use "Robust"
		






Distortions

The tool can deal with various types of code deformations. There are three possible settings, as demonstrated below. Please be aware that when we make the algorithm more robust to distortions, we make it less robust to broken code patterns. For this reason, we should stay with lower settings whenever possible.

Use "Low"	Use "Medium"	Use "High"
		
		Each side is represented with a single line segment.	Each side is represented with a 3-segment line.	Each side is exactly traced with a polyline.

Module Sizes

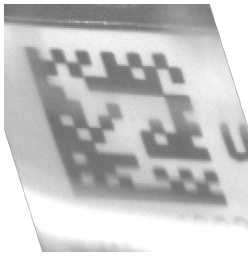
- **MinModuleSize** (for 2D) and **MinThinBarSize** (for 1D) is the expected lower bound of one module (the smallest unit of the code).
- **MaxModuleSize** (for 2D) and **MaxThinBarSize** (for 1D) is the expected upper bound of one module (the smallest unit of the code).

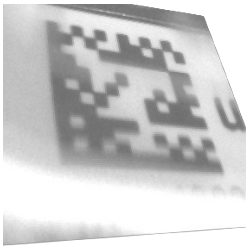
Polarity

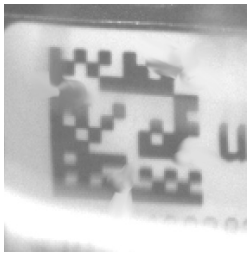
inPolarity – while most codes in the world have black modules printed on a bright background, the tool can also read the opposite. What is more, the "Mixed" polarity is an option for reading some difficult DPM codes that have both bright and dark spots within a single module.

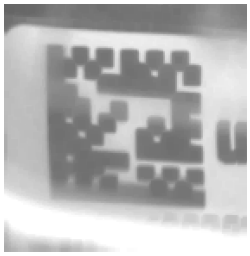
Damaged codes and other difficulties

By using appropriate **inMatrixCodeParams** settings, you can read codes that are partially damaged. See the below table for some of the most common cases.

Use MaxSlant=30	Use AllowPerspective=High	Use AllowBrokenEdges and AllowBrokenTiming	Use AllowOversizedModules
			




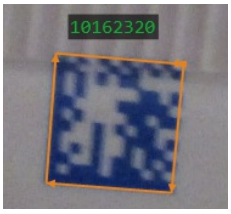




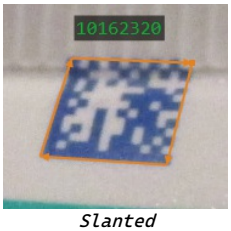
Hints

- Specify the range of possible codes in an image by setting the **inMatrixCodeParams** and **inLinearCodeParams**. The narrower are the settings, the faster the filter works.
  - Set **inDetectorParams.Polarity** to specify whether dark-on-bright or bright-on-dark codes are to be read. If code polarity is inconsistent, use "Mixed" (it may be also a very good option for some DPM codes).
  - Specify the range of possible code sizes with **inMatrixCodeParams.MinRowCount**, **inMatrixCodeParams.MaxRowCount**, **inMatrixCodeParams.MinColumnCount** and **inMatrixCodeParams.MinColumnCount**.
  - Specify the range of possible module sizes (in pixels) with **inMatrixCodeParams.MinModuleSize** and **inMatrixCodeParams.MaxModuleSize** (for 2D codes), or **inLinearCodeParams.MinThinBarSize** and **inLinearCodeParams.MaxThinBarSize** (for 1D codes). Note that the minimum value may highly affect the tool's execution time.
  - When using "FinderPattern" or "DotGrid" methods, also set the **inDetectorParams.DotSize** according to the following rules:
    - Full – no gaps between modules (the modules are fully filled).
    - Large – module gaps up to 25% of the module size; this is the default setting.
    - Medium – module gaps up to 50% of the module size; it may require a bigger Quiet Zone.
    - Small – module gaps up to 75%; comes with no guarantee.
  - Set **inMatrixCodeParams.MaxRectangleRatio** to 1 if you expect to work with square codes only. The value specifies maximal ratio between the length of the longer side to the length of the shorter side.
  - Pay attention to codes that are bent or unevenly printed.
    - For bent codes (e.g. printed on a bottle) use **inDetectorParams.AllowDistortion** = Medium.
    - For unevenly printed codes or ones that are printed on wrinkled material use **inDetectorParams.AllowDistortion** = High.
  - For potentially damaged codes, consider using **inDetectorParams.AllowBrokenEdges** and **inMatrixCodeParams.AllowBrokenTiming**. These settings make the tool more robust against missing pieces of Finder Pattern and Timing Pattern respectively.
- If some codes are not detected, try the following procedure:
  - In the first place, make sure that the symbologies you are trying to read are selected.
  - Also make sure that you have set the right range of module sizes and the code polarity setting.
  - Change **inDetectorParams.PyramidStrategy** and **inDetectorParams.DecodeStrategy** to Strict or Extended.
  - Increase **inDetectorParams.MinContrast** if the noise is high. Decrease it for dark and low-contrast images.
  - Also consider increasing **inDetectorParams.MaxSlant** and **inDetectorParams.AllowPerspective** (especially important for very big codes).
  - If still nothing works, also set **inDetectorParams.FinderTradeoff**, **inDetectorParams.DotSize** and **inDetectorParams.AllowDistortion** to "Nil". This will work slowly, but should read almost everything.

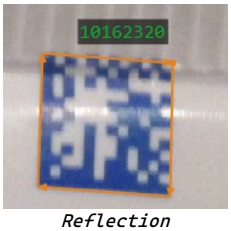
Examples



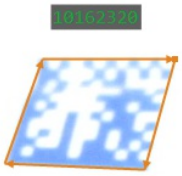
Square



Slanted



Reflection



Overexposure

Simple case.

Dark and lower quality code.

Code viewed from an angle.

Remarks

For maximum reliability of reading codes, we recommend making sure that the image fulfills the following standard requirements:

- Module size should be at least 4.0 pixels. It is possible to read codes with modules as low as 1.25 pixels, but this comes with no guarantee and is highly dependent on the image and printing quality.
- Gaps between dot-printed marks should be not bigger than 50% of the module size, but the less, the better.
- There should be an empty space around the code ("quiet zone"). It should have the width at least equal to the module size. Contamination, additional print, or shadows in this area is the most frequent source of reduced reliability.
- The Finder Pattern slant (angular deviation from 90 degrees) should not be greater than 30 degrees.

For explanation of the used terminology, please refer to the below picture:

ReadSingleCode_IK_Binary

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads a single code in the input image; returns binary data.

Applications: Use this tool when you need access to the raw barcode content.

Syntax

```
void avl::ReadSingleCode_IK_Binary
(
 ImageKit_State& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 avl::CodeInverse1D::Type inInverse,

ReadSingleCode_Z

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads a single 1D barcode or a PDF417 code.

Applications: High-speed barcode reading with simple configuration.

Syntax

```
void avl::ReadSingleCode_Z
(
 ZCode_State& ioState,
 const avl::Image& inImage,
 const atl::Optional<atl::File>& inLoadConfigFile,
 const atl::Optional<atl::File>& inSaveConfigFile,
 atl::Optional<int> inTimeout,
 atl::Optional<int> inThreadCount,
 const avl::Code1DSettings& inCode1DSettings,
 bool inEnablePDF417,
 bool inEnableCode128,
 bool inEnableCode39,
 bool inEnableCode93,
 bool inEnableInterleaved2of5,
 bool inEnableNoRead,
 bool inEnableQualityMetrics,
 atl::Conditional<avl::ZResult>& outResult,
 atl::Conditional<avl::ZQualityMetrics>& outQualityMetrics,
 atl::Conditional<avl::ZNoReadResult>& outNoReadResult
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZCode_State&			Object used to maintain state of the function.
	inImage	const Image&			Input image
	inLoadConfigFile	const Optional<File>&		NIL	Configuration file to be loaded in .bin format. Used to restore previously saved settings – can overwrite other parameters.
	inSaveConfigFile	const Optional<File>&		NIL	Path to save configuration file in .bin format. Used to save current settings for future use.
	inTimeout	Optional<int>	1 – ∞	NIL	Processing timeout in ms
	inThreadCount	Optional<int>	1 – 31	NIL	Number of processing threads
	inCode1DSettings	const Code1DSettings&			Code1D settings
	inEnablePDF417	bool		True	
	inEnableCode128	bool		True	
	inEnableCode39	bool		False	
	inEnableCode93	bool		False	
	inEnableInterleaved2of5	bool		False	
	inEnableNoRead	bool		False	Enable return of the no read results
	inEnableQualityMetrics	bool		False	Enable return of quality metrics
	outResult	Conditional<ZResult>&			Decode results
	outQualityMetrics	Conditional<ZQualityMetrics>&			Quality metrics of decoded codes
	outNoReadResult	Conditional<ZNoReadResult>&			No read result – code outline with the reason why it was not decoded

Requirements

For input **inImage** only pixel formats are supported: uint8.

Read more about pixel formats in Image documentation.

Errors

List of possible exceptions:

Error type	Description
DomainError	ReadSingleCode_Z is not supported on this platform.
DomainError	Not supported inImage pixel format in ReadSingleCode_Z. Supported formats: UInt8.

ReadSingleDataCode

Header: AVL.h
Namespace: avl
Module: Datacodes

Reads a single data code (1D or 2D) in the input image.

Applications: The main tool for reading both linear and matrix codes (Data Matrix, QR Code), including DPM.

Syntax

```
void avl::ReadSingleDataCode
(
 avl::ReadDataCodes_State& ioState,
 const avl::Image& inImage,
 atl::Optional<const avl::Rectangle2D&> inRoi,
 atl::Optional<const avl::CoordinateSystem2D&> inRoiAlignment,
 atl::Optional<const avl::MatrixSymbologies&> inMatrixSymbologies,
 atl::Optional<const avl::LinearSymbologies&> inLinearSymbologies,
 const avl::DataCodeDetectorParams& inDetectorParams,
 const avl::MatrixCodeParams& inMatrixCodeParams,
 const avl::DpmParams& inDpmParams,
 const avl::LinearCodeParams& inLinearCodeParams,
 bool inComputeScores,
 atl::Conditional<avl::DataCode>& outDataCode,
 atl::Array<avl::Path>& outCandidates,
 atl::Optional<avl::Rectangle2D&> outAlignedRoi = atl::NIL,
 atl::Array<avl::DataCode>& outNoReads = atl::Dummy<atl::Array<avl::DataCode>>()
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ReadDataCodes_State&		Object used to maintain state of the function.
→	inImage	const Image&		Input image
→	inRoi	Optional<const Rectangle2D&>	NIL	Region of interest
→	inRoiAlignment	Optional<const CoordinateSystem2D&>	NIL	Coordinate system for the region of interest
→	inMatrixSymbologies	Optional<const MatrixSymbologies&>	NIL	Specifies which matrix symbologies the filter should try to read
→	inLinearSymbologies	Optional<const LinearSymbologies&>	NIL	Specifies which linear symbologies the filter should try to read
→	inDetectorParams	const DataCodeDetectorParams&		Parameters of the code detection algorithm, common for linear and matrix codes
→	inMatrixCodeParams	const MatrixCodeParams&		Parameters specific to matrix (2D) codes
→	inDpmParams	const DpmParams&		Parameters specific to direct part marking codes
→	inLinearCodeParams	const LinearCodeParams&		Parameters specific to linear (1D) codes
→	inComputeScores	bool		Enables computing of confidence scores (slower)
←	outDataCode	Conditional<DataCode>&		A code that has been correctly detected and decoded
←	outCandidates	Array<Path>&		Diagnostic information about detection results
←	outAlignedRoi	Optional<Rectangle2D&>	NIL	Input ROI after transformation (in the image coordinates)
←	outNoReads	Array<DataCode>&	Dummy<Array<DataCode>>()	List of codes that have been detected but not decoded

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedRoi**.

Read more about Optional Outputs.

Description

The filter locates and decodes a single data code (Data Matrix, QR Code or a linear barcode) in an image within a given region (**inRoi**). If there are more codes, the tool may find any of them.

Groups of parameters

The tool's default parameters are selected for reading of high- and medium-quality codes at a good speed. If you need to achieve a higher speed, or read damaged or distorted codes, then some parameters may need to be adjusted. There are three main groups:

1. **inDetectorParams** – parameters of the code detector, common for 1D and 2D codes.
2. **inMatrixCodeParams** – parameters related to 2D code reading (Data Matrix and QR Code).
3. **inLinearCodeParams** – parameters related to 1D code reading (Code 128, EAN/UPC etc.).

Symbology selection

The first choice, and one that you must always make, is to select the code symbologies. Use **inMatrixSymbologies** for reading Data Matrix or QR Codes. Use **inLinearSymbologies** to read 1D types (Code 128, EAN/UPC etc.).

To assure the maximum possible performance, always select only those symbologies that you do need.

NOTE: If you enable one of these sections but leave all the options set to "False", the tool will still perform code detection (1D or 2D) but will skip the decoding phase. It may be useful for testing detector's execution time but should not be used at production.

Detection methods

The most important detector's setting is the detection algorithm, **inDetectorParams.DetectionMethod**. The tool offers three options:

	Finder Edges (default)	**Finder Pattern (basic)**	**Dot Grid (advanced)**
Where it looks?			How it works?	Looks for the edges of the L-shaped pattern. Uses a robust line segment detector internally.	It is a simple method based on blob analysis. Uses dynamic image thresholding to extract the code.	Ignores the finder and timing patterns altogether. Instead, directly recognizes the grid-like structure of the code.
When to use it?	This method is fast and effective even in challenging conditions, including DPM (direct part marking) but may be confused by additional lines appearing near the code. You can fine-tune it with **FinderTradeoff** and **EdgeTracker parameters.**	This method works well only on clearly printed codes with a correct quiet zone. May also handle some dot-codes when setting the **inDetectorParams.DotSize** properly.	This method can detect codes with highly damaged finder and timing patterns. Works best with dot-printed codes, but can work with fully-printed codes when **inDetectorParams.DotSize** is set to "Full".
Works with 1D?	Yes.	Sometimes.	No.

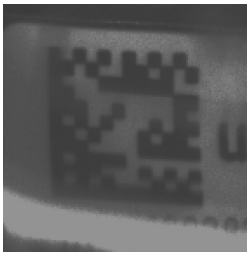
Pyramid strategy

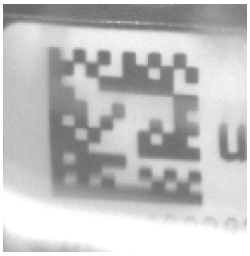
The tool tries to detect codes at different scale levels. It investigates images at different resolutions, starting with the lowest resolution. If it finds a sufficient number of codes at one level, it may skip looking further, thus achieving shorter execution time. If there are no codes in the input image, it will always scan all the levels, resulting in the highest execution time. For this reason, it is very important to set **inMatrixCodeParams.MinModuleSize** and/or **inLinearCodeParams.MinThinBarSize** precisely – setting it too low may significantly increase the tool's execution time.

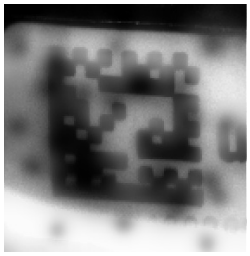
NOTE: If you experience instable execution times, for example, switching between 10 ms and 20 ms, it may indicate that for some images the tool finds a code at a higher level, while for some others it has to process the higher resolution too. For that reason, we also recommend testing time performance on the ReadMultipleDataCodes tool, with **inMaxCodeCount**=1000 and **inAllowMultipleScales**=True. This will assure that no early exit happens, and the execution time will be the maximum of what we may expect with the given settings.

Finder Tradeoff ("FinderEdges" only)

When using the "FinderEdges" method, you should be aware that there is a tradeoff between the ability of the tool to detect rugged (uneven, noised, or dot printed) edges and the ability to detect low contrast edges (or ones neighboring with a very narrow Quite Zone). The default setting is "Balanced". However, if you expect the edges of your code to be relatively straight and clean, but less strong, you may want to change it to "Sensitive". On the other hand, if the edges of the code are highly jagged or the surrounding is noisy, it may be better to choose "Robust". You may also set it to "Auto" and it will test several possibilities at the cost of much higher execution time.

Use "Sensitive"	Use "Balanced"	Use "Robust"
		






Distortions

The tool can deal with various types of code deformations. There are three possible settings, as demonstrated below. Please be aware that when we make the algorithm more robust to distortions, we make it less robust to broken code patterns. For this reason, we should stay with lower settings whenever possible.

Use "Low"	Use "Medium"	Use "High"
		Each side is represented with a single line segment.	Each side is represented with a 3-segment line.	Each side is exactly traced with a polyline.

Module Sizes

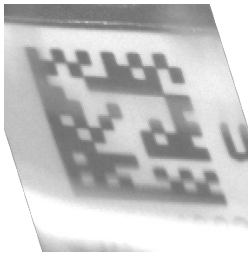
- **MinModuleSize** (for 2D) and **MinThinBarSize** (for 1D) is the expected lower bound of one module (the smallest unit of the code).
- **MaxModuleSize** (for 2D) and **MaxThinBarSize** (for 1D) is the expected upper bound of one module (the smallest unit of the code).

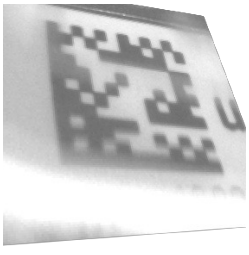
Polarity

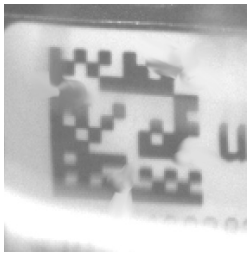
inPolarity – while most codes in the world have black modules printed on a bright background, the tool can also read the opposite. What is more, the "Mixed" polarity is an option for reading some difficult DPM codes that have both bright and dark spots within a single module.

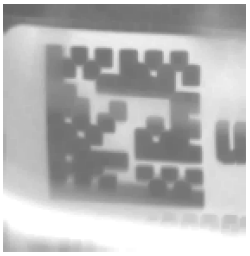
Damaged codes and other difficulties

By using appropriate **inMatrixCodeParams** settings, you can read codes that are partially damaged. See the below table for some of the most common cases.

Use MaxSlant=30	Use AllowPerspective=High	Use AllowBrokenEdges and AllowBrokenTiming	Use AllowOversizedModules
			




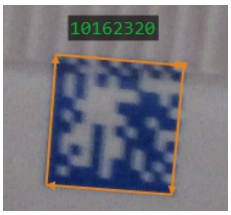




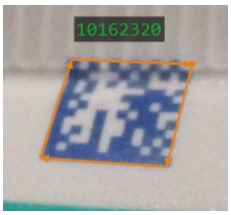
Hints

- Specify the range of possible codes in an image by setting the **inMatrixCodeParams** and **inLinearCodeParams**. The narrower are the settings, the faster the filter works.
  - Set **inDetectorParams.Polarity** to specify whether dark-on-bright or bright-on-dark codes are to be read. If code polarity is inconsistent, use "Mixed" (it may be also a very good option for some DPM codes).
  - Specify the range of possible code sizes with **inMatrixCodeParams.MinRowCount**, **inMatrixCodeParams.MaxRowCount**, **inMatrixCodeParams.MinColumnCount** and **inMatrixCodeParams.MinColumnCount**.
  - Specify the range of possible module sizes (in pixels) with **inMatrixCodeParams.MinModuleSize** and **inMatrixCodeParams.MaxModuleSize** (for 2D codes), or **inLinearCodeParams.MinThinBarSize** and **inLinearCodeParams.MaxThinBarSize** (for 1D codes). Note that the minimum value may highly affect the tool's execution time.
  - When using "FinderPattern" or "DotGrid" methods, also set the **inDetectorParams.DotSize** according to the following rules:
    - Full – no gaps between modules (the modules are fully filled).
    - Large – module gaps up to 25% of the module size; this is the default setting.
    - Medium – module gaps up to 50% of the module size; it may require a bigger Quiet Zone.
    - Small – module gaps up to 75%; comes with no guarantee.
  - Set **inMatrixCodeParams.MaxRectangleRatio** to 1 if you expect to work with square codes only. The value specifies maximal ratio between the length of the longer side to the length of the shorter side.
  - Pay attention to codes that are bent or unevenly printed.
    - For bent codes (e.g. printed on a bottle) use **inDetectorParams.AllowDistortion** = Medium.
    - For unevenly printed codes or ones that are printed on wrinkled material use **inDetectorParams.AllowDistortion** = High.
  - For potentially damaged codes, consider using **inDetectorParams.AllowBrokenEdges** and **inMatrixCodeParams.AllowBrokenTiming**. These settings make the tool more robust against missing pieces of Finder Pattern and Timing Pattern respectively.
- If some codes are not detected, try the following procedure:
  - In the first place, make sure that the symbologies you are trying to read are selected.
  - Also make sure that you have set the right range of module sizes and the code polarity setting.
  - Change **inDetectorParams.PyramidStrategy** and **inDetectorParams.DecodeStrategy** to Strict or Extended.
  - Increase **inDetectorParams.MinContrast** if the noise is high. Decrease it for dark and low-contrast images.
  - Also consider increasing **inDetectorParams.MaxSlant** and **inDetectorParams.AllowPerspective** (especially important for very big codes).
  - If still nothing works, also set **inDetectorParams.FinderTradeoff**, **inDetectorParams.DotSize** and **inDetectorParams.AllowDistortion** to "Nil". This will work slowly, but should read almost everything.

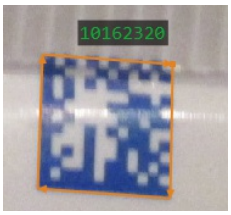
Examples



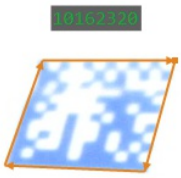
Square



Slanted



Reflection



Overexposure

Simple case.

Dark and lower quality code.

Code viewed from an angle.

Remarks

For maximum reliability of reading codes, we recommend making sure that the image fulfills the following standard requirements:

- Module size should be at least 4.0 pixels. It is possible to read codes with modules as low as 1.25 pixels, but this comes with no guarantee and is highly dependent on the image and printing quality.
- Gaps between dot-printed marks should be not bigger than 50% of the module size, but the less, the better.
- There should be an empty space around the code ("quiet zone"). It should have the width at least equal to the module size. Contamination, additional print, or shadows in this area is the most frequent source of reduced reliability.
- The Finder Pattern slant (angular deviation from 90 degrees) should not be greater than 30 degrees.

For explanation of the used terminology, please refer to the below picture:

99. Histogram Features

Table of content:

- HistogramAverage
- HistogramLocalExtrema
- HistogramMaximum
- HistogramMinimum
- HistogramSize
- HistogramSum

HistogramAverage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the average of histogram bin values.

Syntax

```
void avl::HistogramAverage
(
 const avl::Histogram& inHistogram,
 double& outAverage
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outAverage	double&		Output average

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histogram is empty in HistogramAverage.

See Also

- HistogramMinimum – Computes histogram bar values minimum – its location and value.
- HistogramMaximum – Computes histogram bar values maximum – its location and value.

HistogramLocalExtrema

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the histogram local extrema.

Syntax

```
void avl::HistogramLocalExtrema
(
 const avl::Histogram& inHistogram,
 atl::Optional<const avl::Range&> inRange,
 atl::Optional<double> inMinValue,
 atl::Optional<double> inMaxValue,
 const bool inCyclic,
 const bool inConsiderPlateaus,
 avl::ExtremumType::Type inExtremumType,
 avl::HistogramInterpolationMethod::Type inInterpolationMethod,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::HistogramExtremum>& outLocalExtrema
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inRange	Optional<const Range&>	NIL	Search range
→	inMinValue	Optional<double>	NIL	Minimum value of an extremum
→	inMaxValue	Optional<double>	NIL	Maximum value of an extremum
→	inCyclic	const bool	False	Whether to check differences between the first and last elements
→	inConsiderPlateaus	const bool		Indicates whether the result should include centers of plateau extrema
→	inExtremumType	ExtremumType::Type		Type of extremum to find
→	inInterpolationMethod	HistogramInterpolationMethod::Type	Linear	Histogram bins interpolation method
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker extrema can be detected in the vicinity of stronger ones
←	outLocalExtrema	Array<HistogramExtremum>&		Output histogram extrema

HistogramMaximum

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes histogram bar values maximum - its location and value.

Syntax

```
void avl::HistogramMaximum
(
 const avl::Histogram& inHistogram,
 atl::Optional<const avl::Range&> inRange,
 avl::HistogramInterpolationMethod::Type inInterpolationMethod,
 int& outMaximumLocation,
 float& outPoint,
 double& outMaximumValue
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inRange	Optional<const Range&>	NIL	Search range
→	inInterpolationMethod	HistogramInterpolationMethod::Type		Histogram bins interpolation method
←	outMaximumLocation	int&		Output maximum location
←	outPoint	float&		Output subpixel maximum location
←	outMaximumValue	double&		Output maximum value

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramMaximum.
DomainError	Unsupported interpolation method in HistogramMaximum.

See Also

- HistogramMinimum - Computes histogram bar values minimum - its location and value.
- HistogramAverage - Computes the average of histogram bin values.

HistogramMinimum

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes histogram bar values minimum - its location and value.

Syntax

```
void avl::HistogramMinimum
(
 const avl::Histogram& inHistogram,
 atl::Optional<const avl::Range&> inRange,
 avl::HistogramInterpolationMethod::Type inInterpolationMethod,
 int& outMinimumLocation,
 float& outPoint,
 double& outMinimumValue
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inRange	Optional<const Range&>	NIL	Search range
→	inInterpolationMethod	HistogramInterpolationMethod::Type		Histogram bins interpolation method
←	outMinimumLocation	int&		Output minimum location
←	outPoint	float&		Output subpixel minimum location
←	outMinimumValue	double&		Output minimum value

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramMinimum.
DomainError	Unsupported interpolation method in HistogramMinimum.

See Also

- HistogramAverage - Computes the average of histogram bin values.
- HistogramMaximum - Computes histogram bar values maximum - its location and value.

HistogramSize

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the number of histogram bins.

Syntax

```
void avl::HistogramSize
(
 const avl::Histogram& inHistogram,
 int& outSize
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outSize	int&		Output size

HistogramSum

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the sum of histogram bin values.

Syntax

```
void avl::HistogramSum
(
 const avl::Histogram& inHistogram,
 double& outSum
)
```

Parameters

	Name	Type	Default	Description
	inHistogram	const Histogram&		Input histogram
	outSum	double&		Output sum

100. Histogram Data Statistics

Table of content:

- HistogramDataAverage
- HistogramDataMaximum
- HistogramDataMedian
- HistogramDataMinimum
- HistogramDataNthValue
- HistogramDataQuantile
- HistogramDataSize
- HistogramDataStandardDeviation
- HistogramDataVariance

HistogramDataAverage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the average of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataAverage
(
 const avl::Histogram& inHistogram,
 float& outAverage
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
⬅	outAverage	float&		Average of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataAverage.
DomainError	Input histogram contains negative bins or its data is empty in HistogramDataAverage.

HistogramDataMaximum

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the approximation of the largest value of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataMaximum
(
 const avl::Histogram& inHistogram,
 float& outMaximum
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram	const Histogram&		Input histogram
⬅	outMaximum	float&		Maximum of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataMaximum.
DomainError	The histogrammed data is empty in HistogramDataMaximum.

HistogramDataMedian

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the median of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataMedian
(
 const avl::Histogram& inHistogram,
 float& outMedian
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outMedian	float&		Median of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataMedian.
DomainError	Input histogram contains negative bins or its data is empty in HistogramDataMedian.

See Also

- HistogramDataAverage – Computes the average of the histogrammed numeric data.
- HistogramDataQuantile – Computes the specified quantile of the histogrammed numeric data.
- HistogramDataStandardDeviation – Computes the standard deviation of the histogrammed numeric data.
- HistogramDataVariance – Computes the variance of the histogrammed numeric data.

HistogramDataMinimum

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the approximation of the smallest value of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataMinimum
(
 const avl::Histogram& inHistogram,
 float& outMinimum
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outMinimum	float&		Minimum of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataMinimum.
DomainError	The histogrammed data is empty in HistogramDataMinimum.

HistogramDataNthValue

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes nth smallest (or largest) value of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataNthValue
(
 const avl::Histogram& inHistogram,
 const double inN,
 const avl::SortingOrder::Type inSortingOrder,
 float& outNthValue
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
→	inN	const double		
→	inSortingOrder	const SortingOrder::Type		
←	outNthValue	float&		Nth smallest (or largest) value of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histogram contains negative bins in HistogramDataNthValue.
DomainError	Selected N exceeds index range in HistogramDataNthValue.

HistogramDataQuantile

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the specified quantile of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataQuantile
(
 const avl::Histogram& inHistogram,
 const float inQuantilePoint,
 float& outQuantileValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHistogram	const Histogram&			Input histogram
→	inQuantilePoint	const float	0.0 – 1.0	0.5f	
←	outQuantileValue	float&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataQuantile.
DomainError	Input histogram contains negative bins or its data is empty in HistogramDataQuantile.

See Also

- HistogramDataAverage – Computes the average of the histogrammed numeric data.
- HistogramDataMedian – Computes the median of the histogrammed numeric data.
- HistogramDataStandardDeviation – Computes the standard deviation of the histogrammed numeric data.
- HistogramDataVariance – Computes the variance of the histogrammed numeric data.

HistogramDataSize

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the number of elements of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataSize
(
 const avl::Histogram& inHistogram,
 double& outSize
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outSize	double&		Number of elements of the histogrammed data

HistogramDataStandardDeviation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the standard deviation of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataStandardDeviation
(
 const avl::Histogram& inHistogram,
 float& outStandardDeviation
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outStandardDeviation	float&		Standard deviation of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataStandardDeviation.
DomainError	Input histogram contains negative bins or its data is empty in HistogramDataStandardDeviation.

See Also

- HistogramDataAverage – Computes the average of the histogrammed numeric data.
- HistogramDataMedian – Computes the median of the histogrammed numeric data.
- HistogramDataQuantile – Computes the specified quantile of the histogrammed numeric data.
- HistogramDataVariance – Computes the variance of the histogrammed numeric data.

HistogramDataVariance

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the variance of the histogrammed numeric data.

Syntax

```
void avl::HistogramDataVariance
(
 const avl::Histogram& inHistogram,
 float& outVariance
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Input histogram
←	outVariance	float&		Variance of the histogrammed data

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramDataVariance.
DomainError	Input histogram contains negative bins or its data is empty in HistogramDataVariance.

See Also

- HistogramDataAverage – Computes the average of the histogrammed numeric data.
- HistogramDataMedian – Computes the median of the histogrammed numeric data.
- HistogramDataStandardDeviation – Computes the standard deviation of the histogrammed numeric data.
- HistogramDataQuantile – Computes the specified quantile of the histogrammed numeric data.

101. Histogram Metrics

Table of content:

- HistogramDistance
- HistogramIntersection

HistogramDistance

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the numeric distance between two histograms.

Syntax

```
void avl::HistogramDistance
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 avl::DistanceMeasure::Type inDistanceMeasure,
 double& outDistance
)
```

Parameters

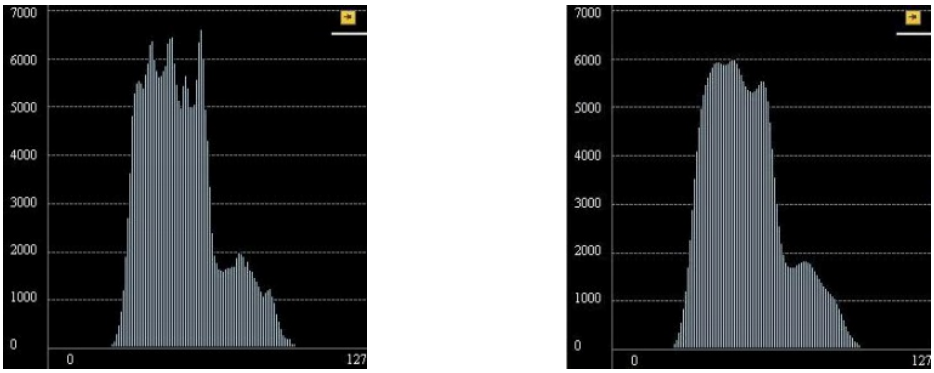
	Name	Type	Default	Description
→	inHistogram1	const Histogram&		First input histogram
→	inHistogram2	const Histogram&		Second input histogram
→	inDistanceMeasure	DistanceMeasure::Type		Measure of distance
←	outDistance	double&		Output distance value

Description

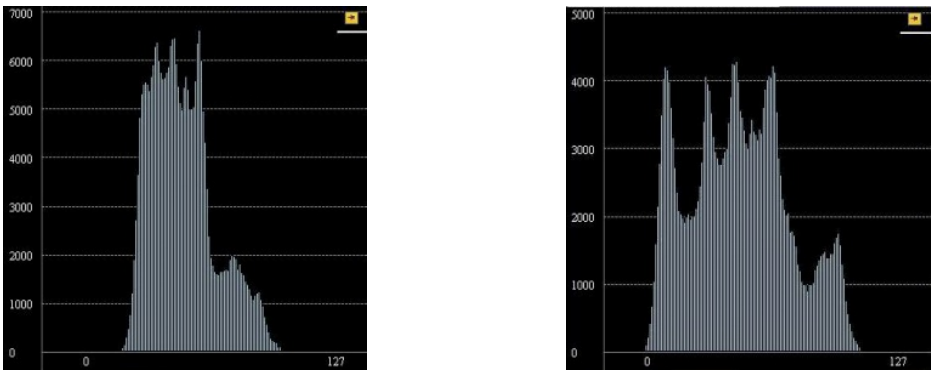
The operation computes the approximate difference between two histograms using the selected distance measure.

- If the **inDistanceMeasure** is set to **MeanError** then the resulting **outDistance** is the average difference between corresponding bins of the histograms.
- If the **inDistanceMeasure** is set to **MeanSquaredError** then the resulting **outDistance** is the average squared difference between corresponding bins of the histograms.

Examples



Mean Squared Error between the sample histograms equals 68302.590.



Mean Squared Error between the sample histograms equals 3043686.

Remarks

- **inHistogram1** and **inHistogram2** must have the same BinSizes, otherwise an error with appropriate description occurs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histograms on input in HistogramDistance.
DomainError	Inconsistent histogram bin sizes / domains in HistogramDistance.
DomainError	Not supported DistanceMeasure in HistogramDistance.

See Also

- ImageHistogram – Computes the histogram of the image pixel values.

HistogramIntersection

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Calculates normalized histogram intersection norm.

Syntax

```
void avl::HistogramIntersection
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 double& outHistogramIntersection
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram1	const Histogram&		First input histogram
→	inHistogram2	const Histogram&		Second input histogram
←	outHistogramIntersection	double&		

Description

The operation computes the normalized histogram intersection defined as:

$$\frac{\sum_{j=1}^{n} \min\left(inHistogram1_j, inHistogram2_j\right)}{\sum_{j=1}^{n} inHistogram2_j}$$

Remarks

- Data sets for the input histograms cannot be empty, otherwise an error with appropriate description occurs,
- **inHistogram1** and **inHistogram2** must have the same BinSizes, otherwise an error with appropriate description occurs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty histogram on input in HistogramIntersection.
DomainError	Input histogram formats are not the same in HistogramIntersection.
DomainError	Negative value in a histogram in HistogramIntersection.

See Also

- ImageHistogram – Computes the histogram of the image pixel values.

102. HTTP

Table of content:

- Http_DecodeURL
- Http_EncodeURL
- Http_SendBinaryData
- Http_SendCustomRequest
- Http_SendRequest_DELETE
- Http_SendRequest_DELETE_ByteBuffer
- Http_SendRequest_GET
- Http_SendRequest_GET_ByteBuffer
- Http_SendRequest_PATCH
- Http_SendRequest_PATCH_ByteBuffer
- Http_SendRequest_PATCH_JSON
- Http_SendRequest_POST
- Http_SendRequest_POST_ByteBuffer
- Http_SendRequest_POST_JSON
- Http_SendRequest_PUT
- Http_SendRequest_PUT_ByteBuffer
- Http_SendRequest_PUT_JSON

Http_DecodeURL

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts text from URL friendly text to a string.

Syntax

```
void avl::Http_DecodeURL
(
 const atl::String& inEncoded,
 atl::String& outDecoded
)
```

Parameters

	Name	Type	Default	Description
→	inEncoded	const String&		Percent encoded string.
←	outDecoded	String&		Decoded string.

Description

Filter decodes an percent-encoded string to the raw text.

More details can be found in Percent-encoding standard.

Examples

String **Node%20%3D%201%2B2%2B3** will be decoded to **Node = 1+2+3**.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Http_EncodeURL – Converts string to URL friendly text.

Http_EncodeURL

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts string to URL friendly text.

Syntax

```
void avl::Http_EncodeURL
(
 const atl::String& inDecoded,
 atl::String& outEncoded
)
```

Parameters

	Name	Type	Default	Description
→	inDecoded	const String&		String to be encoded.
←	outEncoded	String&		Percent-encoded string.

Description

Filter converts a raw text to the format which can be used in a GET or POST request. Most of white spaces are converted to percent encoded characters.

More details can be found in Percent-encoding standard.

Examples

String **Node = 1+2+3** will be encoded to **Node%20%3D%201%2B2%2B3**.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Http_DecodeURL – Converts text from URL friendly text to a string.

Http_SendBinaryData

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a raw HTTP request.

Syntax

```
void avl::Http_SendBinaryData
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const avl::ByteBuffer& inData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::ByteBuffer>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inData	const ByteBuffer&			Binary data to be send.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<ByteBuffer>&			Answer data.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inHeaders and inHeadersData in Http_SendBinaryData.

Http_SendCustomRequest

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a custom HTTP request.

Syntax

```
void avl::Http_SendCustomRequest
(
 const avl::HTTPRequestMethod::Type& inMethod,
 const atl::String& inUrl,
 const atl::Array<atl::String>& inUrlParameters,
 const atl::Array<atl::String>& inUrlParametersData,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const avl::ByteBuffer& inData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::ByteBuffer>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMethod	const HTTPRequestMethod::Type&		GET	Method of the request.
→	inUrl	const String&			URL of the request.
→	inUrlParameters	const Array<String>&			URL parameters. They will be automatically encoded.
→	inUrlParametersData	const Array<String>&			URL parameters. They will be automatically encoded.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inData	const ByteBuffer&			Binary data to be sent.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<ByteBuffer>&			Answer data.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inHeaders and inHeadersData in Http_SendCustomRequest.
DomainError	Different size of inUrlParameters and inUrlParametersData in Http_SendCustomRequest.

Http_SendRequest_DELETE

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a DELETE request to server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_DELETE
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<atl::String>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request. Without parameters.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<String>&			Answer text if provided in UTF-8 encoding.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a DELETE request to the server then waits for the server text answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
DELETE /test?param1=1&param2=2 HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_DELETE_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_DELETE.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_DELETE.
DomainError	Empty inUrl in Http_SendRequest_DELETE.
DomainError	Invalid inUrl in Http_SendRequest_DELETE.

See Also

- Http_SendRequest_GET – Sends a GET request to server and receives a text answer.
- Http_SendRequest_DELETE_ByteBuffer – Sends a DELETE request to server and receives a binary answer.

Http_SendRequest_DELETE_ByteBuffer

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a DELETE request to server and receives a binary answer.

Syntax

```
void avl::Http_SendRequest_DELETE_ByteBuffer
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::ByteBuffer>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request. Without parameters.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<ByteBuffer>&			Answer as binary byte buffer.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a DELETE request to the server then waits for the server answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
DELETE /test?param1=1&param2=2 HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_DELETE_ByteBuffer.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_DELETE_ByteBuffer.
DomainError	Empty inUrl in Http_SendRequest_DELETE_ByteBuffer.
DomainError	Invalid inUrl in Http_SendRequest_DELETE_ByteBuffer.

See Also

- Http_SendRequest_DELETE – Sends a DELETE request to server and receives a text answer.

Also in AVL Lite

Http_SendRequest_GET

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a GET request to server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_GET
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<atl::String>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request. Without parameters.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<String>&			Answer text if provided in UTF-8 encoding.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a GET request to the server. Filter waits for the server text answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
GET /test?param1=1&param2=2 HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_GET_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_GET.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_GET.
DomainError	Empty inUrl in Http_SendRequest_GET.
DomainError	Invalid inUrl in Http_SendRequest_GET.

See Also

Http_SendRequest_GET_ByteBuffer

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a GET request to server and receives a binary answer.

Syntax

```
void avl::Http_SendRequest_GET_ByteBuffer
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::ByteBuffer>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request. Without parameters.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<ByteBuffer>&			Answer as binary byte buffer.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a GET request to the server then waits for the server answer. Filter can be used to download files from the remote server.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
GET /test?param1=1&param2=2 HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_GET_ByteBuffer.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_GET_ByteBuffer.
DomainError	Empty inUrl in Http_SendRequest_GET_ByteBuffer.
DomainError	Invalid inUrl in Http_SendRequest_GET_ByteBuffer.

See Also

- Http_SendRequest_POST – Sends a POST request to the server and receives a text answer.

Http_SendRequest_PATCH

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a PATCH request to the server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_PATCH
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<atl::String>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<String>&			Answer text if provided in UTF-8 encoding.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a PATCH request to the server using **application/x-www-form-urlencoded** format. Filter waits for the server text answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
PATCH /test HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
Content-Length: 17
Content-Type: application/x-www-form-urlencoded

param1=1&param2=2
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_PATCH_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_PATCH.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_PATCH.
DomainError	Empty inUrl in Http_SendRequest_PATCH.
DomainError	Invalid inUrl in Http_SendRequest_PATCH.

Http_SendRequest_PATCH_ByteBuffer

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a PATCH request to the server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_PATCH_ByteBuffer
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::ByteBuffer>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 - ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<ByteBuffer>&			Answer as a binary byte buffer.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a PATCH request to the server using **application/x-www-form-urlencoded** format. Filter waits for the server binary answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
PATCH /test HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
Content-Length: 17
Content-Type: application/x-www-form-urlencoded

param1=1&param2=2
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_PATCH_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_PATCH_ByteBuffer.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_PATCH_ByteBuffer.
DomainError	Empty inUrl in Http_SendRequest_PATCH_ByteBuffer.
DomainError	Invalid inUrl in Http_SendRequest_PATCH_ByteBuffer.

- Http_SendRequest_PATCH_JSON – Sends a PATCH request in JSON format to the server and receives a text answer.

Also in AVL Lite

Http_SendRequest_PATCH_JSON

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a PATCH request in JSON format to the server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_PATCH_JSON
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::String& inJsonData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<atl::String>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inJsonData	const String&			Request JSON to send.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<String>&			Answer text if provided in UTF-8 encoding.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a PATCH request to the server using **application/json** format. Filter waits for the text server answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inJsonData** = "{'value': 5}"

Request sent to the server:

```
PATCH /test HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: application/json
Content-Type: application/json
charset: utf-8
Content-Length: 12

{'value': 5}
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_PATCH_JSON.
DomainError	Empty inUrl in Http_SendRequest_PATCH_JSON.
DomainError	Invalid inUrl in Http_SendRequest_PATCH_JSON.

Http_SendRequest_POST

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Sends a POST request to the server and receives a text answer.

Syntax

```
void avl::Http_SendRequest_POST
(
 const atl::String& inUrl,
 const atl::Array<atl::String>& inHeaders,
 const atl::Array<atl::String>& inHeadersData,
 const atl::Array<atl::String>& inFields,
 const atl::Array<atl::String>& inFieldsData,
 int inTimeout,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<atl::String>& outAnswer,
 int& outResponseCode
)
```

Parameters

	Name	Type	Range	Default	Description
→	inUrl	const String&			URL of request.
→	inHeaders	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inHeadersData	const Array<String>&			Request headers to send. They will be automatically encoded.
→	inFields	const Array<String>&			Request data to send. It will be automatically encoded.
→	inFieldsData	const Array<String>&			Request data to send. It will be automatically encoded.
→	inTimeout	int	0 – ∞	60	Request timeout in seconds.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outAnswer	Conditional<String>&			Answer text if provided in UTF-8 encoding.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a POST request to the server using **application/x-www-form-urlencoded** format. Filter waits for the server text answer.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
POST /test HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
Content-Length: 17
Content-Type: application/x-www-form-urlencoded

param1=1&param2=2
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_POST_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_POST.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_POST.
DomainError	Empty inUrl in Http_SendRequest_POST.
DomainError	Invalid inUrl in Http_SendRequest_POST.

←	outAnswer	Conditional<ByteBuffer>&			Answer as a binary byte buffer.
←	outResponseCode	int&			Answer code. Typically 200 for OK.

Description

Filter sends a POST request to the server using **application/x-www-form-urlencoded** format. Filter waits for the server binary answer. Filter can be used to download files from the remote server.

When **inCaCertFile** is set to Auto, certificates installed in the operating system are used, otherwise only certificates from the input file are used.

Examples

Filter executed with parameters:

- **inUrl** = http://localhost/test
- **inFields** = ["param1", "param2"]
- **inFieldsData** = ["1", "2"]

Request sent to the server:

```
POST /test HTTP/1.1
Host: localhost
User-Agent: Aurora Vision/1.0
Accept: */*
Content-Length: 17
Content-Type: application/x-www-form-urlencoded

param1=1&param2=2
```

It is also possible to include custom headers in the request. For this purpose, **inHeaders** and **inHeadersData** parameters are used.

Using the following values for these parameters:

- **inHeaders** = ["Header1", "Header2"]
- **inHeadersData** = ["value1", "value2"]

causes the following headers to be added to the request:

```
Header1: value1
Header2: value2
```

Remarks

Filter only accepts text answers encoded using UTF-8 or plain ASCII. To receive answer in arbitrary format please use Http_SendRequest_POST_ByteBuffer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different size of inFields and inFieldsData in Http_SendRequest_POST_ByteBuffer.
DomainError	Different size of inHeaders and inHeadersData in Http_SendRequest_POST_ByteBuffer.
DomainError	Empty inUrl in Http_SendRequest_POST_ByteBuffer.

103. Nearest Neighbors

Table of content:

- KNN_Classify
- KNN_Init
- KNN_Train

KNN_Classify

Header: AVL.h
Namespace: avl
Module: FoundationPro

Classify data using the KNN classifier.

Syntax

```
void avl::KNN_Classify
(
 const avl::KNNModel& inKNNModel,
 const atl::Array<float>& inFeature,
 const int inK,
 const avl::Metric::Type inDistanceType,
 int& outClass
)
```

Parameters

	Name	Type	Range	Default	Description
→	inKNNModel	const KNNModel&			Trained KNN model
→	inFeature	const Array<float>&			Vector of features
→	inK	const int	1 – +∞		Numbers of neighbors
→	inDistanceType	const Metric::Type			Geometry distance type used to calculate neighbors
←	outClass	int&			

Errors

List of possible exceptions:

Error type	Description
DomainError	The inFeature has different dimensions count than KNNModel in KNN_Classify.
DomainError	The inK is bigger than data samples count in KNN_Classify.
DomainError	Using not trained classifier in KNN_Classify.

KNN_Init

Header: AVL.h
Namespace: avl
Module: FoundationPro

Initializes the KNN classifier.

Syntax

```
void avl::KNN_Init
(
 const int inClassCount,
 const int inDimensionCount,
 avl::KNNModel& outKNNModel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inClassCount	const int	2 – +∞		Number of classes
→	inDimensionCount	const int	1 – +∞		Length of feature vector
←	outKNNModel	KNNModel&			Initialized KNN model

Errors

List of possible exceptions:

Error type	Description
DomainError	At least two classes must be provided.
DomainError	Feature vector should have at least one dimension.

KNN_Train

Header: AVL.h
Namespace: avl
Module: FoundationPro

Trains KNN classifier using sample data.

Syntax

```
void avl::KNN_Train
(
 const avl::KNNModel& inKNNModel,
 const atl::Array<atl::Array<float> >& inFeatures,
 const atl::Array< int >& inClasses,
 avl::KNNModel& outKNNModel
)
```

Parameters

	Name	Type	Default	Description
→	inKNNModel	const KNNModel&		Initialized KNN model
→	inFeatures	const Array<Array<float> >&		Array of features array
→	inClasses	const Array< int >&		Array of classes corresponding to feature array elements
←	outKNNModel	KNNModel&		Trained KNN model

Errors

List of possible exceptions:

Error type	Description
DomainError	Array inClasses contains negative values in KNN_Train.
DomainError	Array inClasses contains values grater than maximal class value in KNN_Train.
DomainError	Input array inClasses is empty in KNN_Train.
DomainError	Input array inFeatures is empty in KNN_Train.
DomainError	Input inFeatures contains array of different sizes in KNN_Train.
DomainError	The inFeatures size is different than inClasses size in KNN_Train.
DomainError	Using uninitialized classifier in KNN_Train.

104. Texture Analysis

Table of content:

- LawsFilter
- LinearBinaryPattern

LawsFilter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Filters image with one of the classic LAWS filter.

Syntax

```
void avl::LawsFilter
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const avl::LawsFilterType::Type inVerticalFilter,
 const avl::LawsFilterType::Type inHorizontalFilter,
 const avl::LawsFilterSize::Type inFilterSize,
 const int inMacroBlockSize,
 const bool inNormalizeLocalContrast,
 avl::Image& outTextureImage,
 avl::Image& outTextureEnergyImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input mono image.
→	inRoi	Optional<const Region&>		NIL	Region of Interest.
→	inVerticalFilter	const LawsFilterType::Type		Level	Vertical part of filter.
→	inHorizontalFilter	const LawsFilterType::Type		Edge	Horizontal part of filter.
→	inFilterSize	const LawsFilterSize::Type			Filter window size.
→	inMacroBlockSize	const int	3 – ∞	15	Macroblock is used to gather generated texture energy.
→	inNormalizeLocalContrast	const bool		False	Whether to normalize image before processing.
←	outTextureImage	Image&			Filtered image.
←	outTextureEnergyImage	Image&			Texture energy (AVG).

Requirements

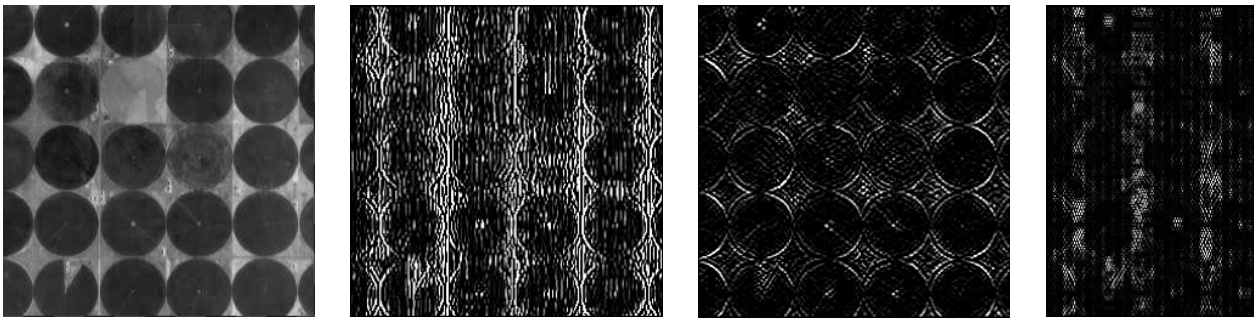
For input **inImage** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

Description

The operation applies texture filters to input image to obtain energy measures.
Laws filter types are: Level, Edge, Wave, Spot, Ripple, Oscillation and Undulation.

Examples



From left: sample image, applied Level and Wave filters, Spot and Edge, Spot and Ripple.

Errors

List of possible exceptions:

Error type	Description
DomainError	Laws filters can be applied to single channel images only.
DomainError	Not supported inImage pixel format in LawsFilter. Supported formats: 1xUInt8.

LinearBinaryPattern

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates histogram and map of Linear Binary Patterns (with radius 1 and size 8) of provided image.

Syntax

```
void avl::LinearBinaryPattern
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::LinearBinaryPatternType::Type inPatternType,
 avl::Histogram& outPatternHistogram,
 avl::Image& outTextureImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Mono-channel image.
→	inRoi	Optional<const Region&>	NIL	Region of Interest.
→	inPatternType	LinearBinaryPatternType::Type		Type of LBP to produce.
←	outPatternHistogram	Histogram&		Histogram of LBP codes found in inImage.
←	outTextureImage	Image&		LBP map of input image.

Requirements

For input **inImage** only pixel formats are supported: 1×uint8.

Read more about pixel formats in Image documentation.

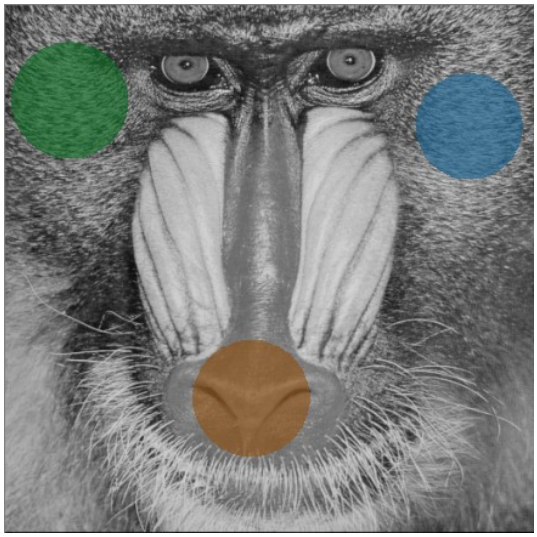
Description

The LPB histogram (treated as a 256 dimensional feature vector) is a texture visual descriptor useful for texture classification. It is obtained by calculating a pattern for each pixel, and then producing a histogram from all these numbers. The pattern is a 8-bit array (coded in uint8) with results of comparisons of the center pixel value to all its neighbours.
Following types of LPB can be calculated:

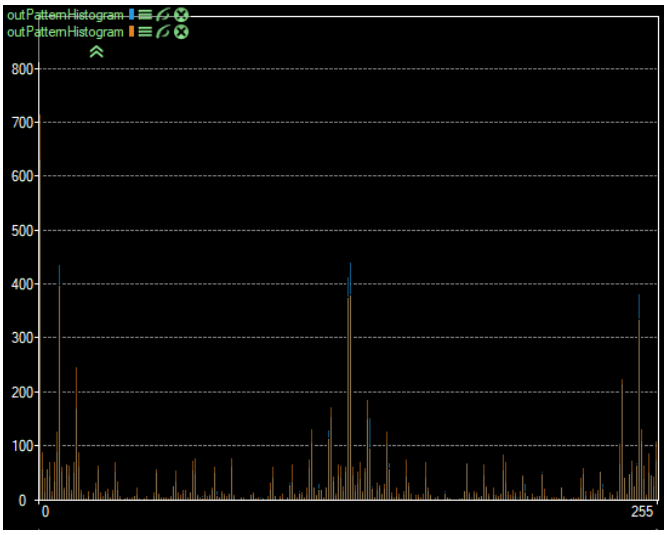
- **Plain**
- **RotationInvariant** - all patterns (and thus histogram bins) that can be obtained by binary shifts from each other are merged into one
- **Uniform** - non-uniform patterns *(these containing more than two 01 or 10 transitions - e.g. 00110010 has 4)* are merged into one bin
- **UniformRotationInvariant** - apply both RotationInvariant and Uniform operations

More information can be found at https://en.wikipedia.org/wiki/Local_binary_patterns

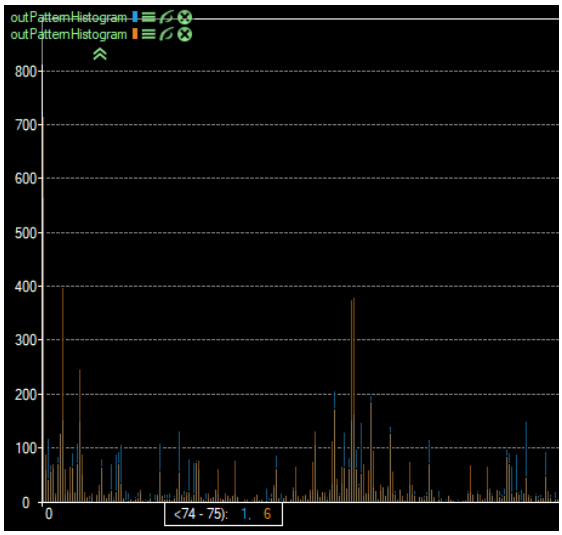
Examples



Source image with following ROIs defined:
top-left fur (reference), top-right fur, and bottom nose.



LBP histograms calculated for top-left and top-right regions (different parts of fur)
*The mean-squared distance between these feature vectors (histograms) is **264,6**.*



LBP histograms calculated for top-left region an region (nose)
*The mean-squared distance between these feature v **1472,3**.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Not supported inImage pixel format in LinearBinaryPattern. Supported formats: 1xUInt8.

105. Geometry 3D Interpolations

Table of content:

- LerpPoints3D
- LerpSegments3D
- LerpVectors3D

LerpPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Linearly interpolates between two points in 3D.

Syntax

```
void avl::LerpPoints3D
(
 const avl::Point3D& inPoint0,
 const avl::Point3D& inPoint1,
 const float inLambda,
 avl::Point3D& outPoint3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint0	const Point3D&			
→	inPoint1	const Point3D&			
→	inLambda	const float	-∞ - ∞	0.5f	Interpolation between the input points where 0.0 value is equal to inPoint0 and 1.0 to inPoint1
←	outPoint3D	Point3D&			

LerpSegments3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Linearly interpolates between two segments in 3D.

Syntax

```
void avl::LerpSegments3D
(
 const avl::Segment3D& inSegment0,
 const avl::Segment3D& inSegment1,
 float inLambda,
 avl::Segment3D& outSegment3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSegment0	const Segment3D&			
→	inSegment1	const Segment3D&			
→	inLambda	float	-∞ - ∞	0.5f	Interpolation between the input segments where 0.0 value is equal to inSegment0 and 1.0 to inSegment
←	outSegment3D	Segment3D&			

LerpVectors3D

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Linearly interpolates between two 3D vectors.

Syntax

```
void avl::LerpVectors3D
(
 const avl::Vector3D& inVector0,
 const avl::Vector3D& inVector1,
 const float inLambda,
 avl::Vector3D& outVector3D
)
```

Parameters

	Name	Type	Range	Default	Description
→	inVector0	const Vector3D&			
→	inVector1	const Vector3D&			
→	inLambda	const float	-∞ - ∞	0.5f	Interpolation between the input 3D vectors where 0.0 value is equal to inVector0 and 1.0 to inVector1
←	outVector3D	Vector3D&			

106. Regression Analysis

Table of content:

LinearRegression

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes linear regression of given point set.

Syntax

```
void avl::LinearRegression
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float> &> inXValues,
 avl::LinearFunction& outLinearFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals,
 float& outRSquared
)
```

Parameters

	Name	Type	Default	Description
→	inYValues	const Array<float>&		Sequence of ordinates
→	inXValues	Optional<const Array<float> &>	NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
←	outLinearFunction	LinearFunction&		Linear function approximating the given point set
←	outEstimatedValues	Array<float>&		The result of application of the computed function to the X values
←	outResiduals	Array<float>&		Difference between an input Y value and the corresponding estimated value
←	outRSquared	float&		Coefficient of determination of output function

Description

The operation fits a straight line through the set of points in such a way, that sum of squared distances (residuals) between points and fitted line is as small as possible.
Fitted line parameters are calculated as follows:

$$B = \frac{n\sum_{i=0}^{n} x_i y_i - \sum_{i=0}^{n} x_i \sum_{i=0}^{n} y_i}{n\sum_{i=0}^{n} x_i^2 - \sum_{i=0}^{n} x^2}$$

$$A = \frac{\sum_{i=0}^{n} x_i}{n} - B\frac{\sum_{i=0}^{n} y_i}{n}$$

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in LinearRegression.

LinearRegression_LTE

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes linear regression of given point set using Least Trimmed Error algorithm.

Syntax

```
void avl::LinearRegression_LTE
(
 const atl::Array<float>& inYValues,
 const atl::Optional<const atl::Array<float>&> inXValues,
 int inSeedSubsetSize,
 atl::Optional<int> inEvalSubsetSize,
 avl::LinearFunction& outLinearFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals,
 atl::Array<float>& outYInliers,
 atl::Array<float>& outXInliers,
 float& outLTError,
 int& diagIterationCount = atl::Dummy<int>()
)
```

Parameters

	Name	Type	Range	Default	Description
→	inYValues	const Array<float>&			Sequence of ordinates
→	inXValues	const Optional<const Array<float>&>		NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inSeedSubsetSize	int	2 – 10	3	Number of points in one combination for getting a sample line
→	inEvalSubsetSize	Optional<int>	3 – ∞	NIL	Number of closest points used for evaluation of a sample line, or Auto if seed points are to be used
←	outLinearFunction	LinearFunction&			Linear function approximating the given point set
←	outEstimatedValues	Array<float>&			The result of application of the computed function to the X values
←	outResiduals	Array<float>&			Difference between an input Y value and the corresponding estimated value
←	outYInliers	Array<float>&			Coordinate of the inlying points of the best LTE line
←	outXInliers	Array<float>&			Coordinate of the inlying points of the best LTE line
←	outLTError	float&			The Least Trimmed Error
🔍	diagIterationCount	int&			Number of combinations considered

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in LinearRegression_LTE.
DomainError	Inconsistent size of arrays in LinearRegression_LTE.

LinearRegression_M

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes linear regression of given point set using selected M-estimator for outlier suppression.

Syntax

```
void avl::LinearRegression_M
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float>&> inXValues,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::LinearFunction&> inInitialLinearFunction,
 avl::LinearFunction& outLinearFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals,
 atl::Optional<atl::Array<float>&> outYInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outXInliers = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inYValues	const Array<float>&			Sequence of ordinates
→	inXValues	Optional<const Array<float>&>		NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialLinearFunction	Optional<const LinearFunction&>		NIL	Initial approximation of the output linear function (if available)
←	outLinearFunction	LinearFunction&			Linear function approximating the given point set
←	outEstimatedValues	Array<float>&			The result of application of the computed function to the X values
←	outResiduals	Array<float>&			Difference between an input Y value and the corresponding estimated value
←	outYInliers	Optional<Array<float>&>		NIL	Coordinate of the inlying points of the best line
←	outXInliers	Optional<Array<float>&>		NIL	Coordinate of the inlying points of the best line

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outYInliers**, **outXInliers**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in LinearRegression_M.

LinearRegression_RANSAC

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes linear regression of given point set using RANSAC.

Syntax

```
void avl::LinearRegression_RANSAC
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float>& > inXValues,
 atl::Optional<int> inMaxOutlierCount,
 float inMaxInlierDistance,
 atl::Optional<int> inIterationCount,
 avl::LinearFunction& outLinearFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals
)
```

Parameters

	Name	Type	Default	Description
→	inYValues	const Array<float>&		Sequence of ordinates
→	inXValues	Optional<const Array<float>& >	NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inMaxOutlierCount	Optional<int>	NIL	Determines how many outlier points can be present to end the search
→	inMaxInlierDistance	float		Distance from a line for point to be considered an inlier
→	inIterationCount	Optional<int>	NIL	Number of iterations; Auto means that all point pairs will be used
←	outLinearFunction	LinearFunction&		Linear function approximating the given point set
←	outEstimatedValues	Array<float>&		The result of application of the computed function to the X values
←	outResiduals	Array<float>&		Difference between an input Y value and the corresponding estimated value

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in LinearRegression_RANSAC.

LinearRegression_TheilSen

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes linear regression of given point set using TheilSen algorithm.

Syntax

```
void avl::LinearRegression_TheilSen
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float>&> inXValues,
 avl::TheilSenVariant::Type inVariant,
 avl::LinearFunction& outLinearFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals
)
```

Parameters

	Name	Type	Default	Description
→	inYValues	const Array<float>&		Sequence of ordinates
→	inXValues	Optional<const Array<float>&>	NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inVariant	TheilSenVariant::Type		Switches between Theil-Sen and Siegel methods
←	outLinearFunction	LinearFunction&		Linear function approximating the given point set
←	outEstimatedValues	Array<float>&		The result of application of the computed function to the X values
←	outResiduals	Array<float>&		Difference between an input Y value and the corresponding estimated value

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty array of points in LinearRegression_TheilSen.
DomainError	Inconsistent size of arrays in LinearRegression_TheilSen.

QuadraticRegression

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes quadratic regression of given point set.

Syntax

```
void avl::QuadraticRegression
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float> &> inXValues,
 avl::QuadraticFunction& outQuadraticFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals,
 float& outRSquared
)
```

Parameters

	Name	Type	Default	Description
→	inYValues	const Array<float>&		Sequence of ordinates
→	inXValues	Optional<const Array<float> &>	NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
←	outQuadraticFunction	QuadraticFunction&		Quadratic function approximating the given point set
←	outEstimatedValues	Array<float>&		The result of application of the computed function to the X values
←	outResiduals	Array<float>&		Difference between an input Y value and the corresponding estimated value
←	outRSquared	float&		Coefficient of determination of output function

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in QuadraticRegression.

QuadraticRegression_M

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes quadratic regression of given point set using selected M-estimator for outlier suppression.

Syntax

```
void avl::QuadraticRegression_M
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float>&> inXValues,
 avl::MEstimator::Type inOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::QuadraticFunction&> inInitialQuadraticFunction,
 avl::QuadraticFunction& outQuadraticFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals,
 atl::Optional<atl::Array<float>&> outYInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outXInliers = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inYValues	const Array<float>&			Sequence of ordinates
→	inXValues	Optional<const Array<float>&>		NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialQuadraticFunction	Optional<const QuadraticFunction&>		NIL	Initial approximation of the output quadratic function (if available)
←	outQuadraticFunction	QuadraticFunction&			Quadratic function approximating the given point set
←	outEstimatedValues	Array<float>&			The result of application of the computed function to the X values
←	outResiduals	Array<float>&			Difference between an input Y value and the corresponding estimated value
←	outYInliers	Optional<Array<float>&>		NIL	Coordinate of the inlying points of the best parabola
←	outXInliers	Optional<Array<float>&>		NIL	Coordinate of the inlying points of the best parabola

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outYInliers**, **outXInliers**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in QuadraticRegression_M.

QuadraticRegression_RANSAC

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes quadratic regression of given point set using RANSAC.

Syntax

```
void avl::QuadraticRegression_RANSAC
(
 const atl::Array<float>& inYValues,
 atl::Optional<const atl::Array<float>& > inXValues,
 atl::Optional<int> inMaxOutlierCount,
 float inMaxInlierDistance,
 atl::Optional<int> inIterationCount,
 avl::QuadraticFunction& outQuadraticFunction,
 atl::Array<float>& outEstimatedValues,
 atl::Array<float>& outResiduals
)
```

Parameters

	Name	Type	Range	Default	Description
→	inYValues	const Array<float>&			Sequence of ordinates
→	inXValues	Optional<const Array<float>& >		NIL	Sequence of abscissae, or {0, 1, 2, ...} by default
→	inMaxOutlierCount	Optional<int>	0 – ∞	NIL	Determines how many outlier points can be present to end the search
→	inMaxInlierDistance	float	0.0 – ∞		Distance from a parabola for point to be considered an inlier
→	inIterationCount	Optional<int>	1 – ∞	NIL	Number of iterations; Auto means that all point triples will be used
←	outQuadraticFunction	QuadraticFunction&			Quadratic function approximating the given point set
←	outEstimatedValues	Array<float>&			The result of application of the computed function to the X values
←	outResiduals	Array<float>&			Difference between an input Y value and the corresponding estimated value

Errors

List of possible exceptions:

Error type	Description
DomainError	Inconsistent size of arrays in QuadraticRegression_RANSAC.

Statistics_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes basic statistical information out of an array of real numbers. The array must be not empty.

Syntax

```
void avl::Statistics_OfArray
(
 const atl::Array<float>& inValues,
 const int inOutlierCount,
 const bool inUseSampleFormula,
 atl::Optional<float&> outMean = atl::NIL,
 atl::Optional<float&> outMedian = atl::NIL,
 atl::Optional<float&> outStandardDeviation = atl::NIL,
 atl::Optional<float&> outMinimum = atl::NIL,
 atl::Optional<float&> outMaximum = atl::NIL,
 atl::Optional<float&> outSpread = atl::NIL,
 atl::Optional<float&> outLinearTrend = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inValues	const Array<float>&			Values used to compute statistical informations
→	inOutlierCount	const int	0 – +∞	0	Defines how many outliers should be removed from the input values
→	inUseSampleFormula	const bool		False	Defines, whether to use population, or sample formulas.
←	outMean	Optional<float&>		NIL	Mean of the input values
←	outMedian	Optional<float&>		NIL	Median of the input values
←	outStandardDeviation	Optional<float&>		NIL	Standard deviation of the input values, treated as population
←	outMinimum	Optional<float&>		NIL	Minimum of the input values
←	outMaximum	Optional<float&>		NIL	Maximum of the input values
←	outSpread	Optional<float&>		NIL	Difference between maximum and minimum of the input values
←	outLinearTrend	Optional<float&>		NIL	First parameter of the linear regression function (multiplier)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMean**, **outMedian**, **outStandardDeviation**, **outMinimum**, **outMaximum**, **outSpread**, **outLinearTrend**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	No data available on input in Statistics_OfArray.

Statistics_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes basic statistical information out of real numbers appearing in consecutive iterations.

Syntax

```
void avl::Statistics_OfLoop
(
 Statistics_OfLoopState& ioState,
 const float inValue,
 const int inBufferSize,
 const int inOutlierCount,
 const bool inUseSampleFormula,
 atl::Optional<float&> outMean = atl::NIL,
 atl::Optional<float&> outMedian = atl::NIL,
 atl::Optional<float&> outStandardDeviation = atl::NIL,
 atl::Optional<float&> outMinimum = atl::NIL,
 atl::Optional<float&> outMaximum = atl::NIL,
 atl::Optional<float&> outSpread = atl::NIL,
 atl::Optional<float&> outLinearTrend = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Statistics_OfLoopState&			Object used to maintain state of the function.
	inValue	const float			Value used to compute statistical informations
	inBufferSize	const int	1 – +∞	10	Defines how many numbers are taken into account
	inOutlierCount	const int	0 – +∞	0	Defines how many outliers should be removed from the input values
	inUseSampleFormula	const bool			Defines, whether to use population, or sample formulas.
	outMean	Optional<float&>		NIL	Mean of the input values
	outMedian	Optional<float&>		NIL	Median of the input values
	outStandardDeviation	Optional<float&>		NIL	Standard deviation of the input values
	outMinimum	Optional<float&>		NIL	Minimum of the input values
	outMaximum	Optional<float&>		NIL	Maximum of the input values
	outSpread	Optional<float&>		NIL	Difference between maximum and minimum of the input values
	outLinearTrend	Optional<float&>		NIL	First parameter of the linear regression function (multiplier)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMean**, **outMedian**, **outStandardDeviation**, **outMinimum**, **outMaximum**, **outSpread**, **outLinearTrend**.

Read more about Optional Outputs.

107. Camera Calibration IO

Table of content:

- LoadAnyCameraModel
- LoadRectificationMap
- LoadRectificationTransform
- SaveAnyCameraModel
- SaveRectificationMap
- SaveRectificationTransform

LoadAnyCameraModel

Header: AVL.h
Namespace: avl
Module: Calibration

Loads serialized AnyCameraModel object from AVDATA file.

Syntax

```
void avl::LoadAnyCameraModel
(
 const atl::File& inFilename,
 avl::AnyCameraModel& outAnyCameraModel
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outAnyCameraModel	AnyCameraModel&		Deserialized output AnyCameraModel

LoadRectificationMap

Header: AVL.h
Namespace: avl
Module: Calibration

Loads serialized RectificationMap object from AVDATA file.

Syntax

```
void avl::LoadRectificationMap
(
 const atl::File& inFilename,
 avl::RectificationMap& outRectificationMap
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outRectificationMap	RectificationMap&		Deserialized output RectificationMap

LoadRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Loads serialized RectificationTransform object from AVDATA file.

Syntax

```
void avl::LoadRectificationTransform
(
 const atl::File& inFilename,
 avl::RectificationTransform& outRectificationTransform
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outRectificationTransform	RectificationTransform&		Deserialized output LoadRectificationTransform

SaveAnyCameraModel

Header: AVL.h
Namespace: avl
Module: Calibration

Saves serialized AnyCameraModel object as AVDATA file.

Syntax

```
void avl::SaveAnyCameraModel
(
 const avl::AnyCameraModel& inAnyCameraModel,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inAnyCameraModel	const AnyCameraModel&		AnyCameraModel to be serialized
➡	inFilename	const File&		Name of the target file

SaveRectificationMap

Header: AVL.h
Namespace: avl
Module: Calibration

Saves serialized RectificationMap object as AVDATA file.

Syntax

```
void avl::SaveRectificationMap
(
 const avl::RectificationMap& inRectificationMap,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inRectificationMap	const RectificationMap&		RectificationMap to be serialized
➡	inFilename	const File&		Name of the target file

SaveRectificationTransform

Header: AVL.h
Namespace: avl
Module: Calibration

Saves serialized RectificationTransform object as AVDATA file.

Syntax

```
void avl::SaveRectificationTransform
(
 const avl::RectificationTransform& inRectificationTransform,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
➡	inRectificationTransform	const RectificationTransform&		RectificationTransform to be serialized
➡	inFilename	const File&		Name of the target file

108. Interoperability

Table of content:

- LoadEntities_FromDxf
- LoadImage_FromDxf
- LoadImage_FromWebsite
- LoadPoint3DGrid
- LoadPoint3DGridWithImage
- LoadSurfaceWithImage
- SavePoint3DGrid

LoadEntities_FromDxf

Header: AVL.h
Namespace: avl
Module: FoundationPro

Loads entities from a DXF file as an array of point arrays.

Syntax

```
void avl::LoadEntities_FromDxf
(
 const atl::File& inDxfFile,
 const float inScale,
 atl::Optional<const atl::Array<atl::String> &> inLayersToDraw,
 avl::Point2D& outOrigin,
 atl::Array<atl::Array<avl::Point2D> >& outEntities,
 atl::Array<atl::String>& diagFileLayersNames
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDxfFile	const File&			
→	inScale	const float	0.0 – ∞	10.0f	Scale (pixels per millimeter)
→	inLayersToDraw	Optional<const Array<String> &>		NIL	Names of layers to draw. Names of all layers are available at the 'diagFileLayersNames' output
←	outOrigin	Point2D&			Location of the origin from DXF on 'outImage'
←	outEntities	Array<Array<Point2D> >&			
🔍	diagFileLayersNames	Array<String>&			Names of all layers in DXF file

Platform support

This operation is only supported on the Microsoft Windows operating system.

LoadImage_FromDxf

Header: AVL.h
Namespace: avl
Module: FoundationPro

Loads data from a DXF file as an image.

Syntax

```
void avl::LoadImage_FromDxf
(
 const atl::File& inDxfFile,
 const float inScale,
 const atl::Optional<avl::Size> inSize,
 const avl::Pixel& inBackgroundColor,
 atl::Optional<const atl::Array<atl::String> &> inLayersToDraw,
 avl::Point2D& outOrigin,
 avl::Image& outImage,
 atl::Array<atl::String>& diagFileLayersNames
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDxfFile	const File&			
→	inScale	const float	0.0 – ∞	10.0f	Scale (pixels per millimeter)
→	inSize	const Optional<Size>		NIL	Size of the output image. Scaled entities from file will be centered on image
→	inBackgroundColor	const Pixel&			
→	inLayersToDraw	Optional<const Array<String> &>		NIL	Names of layers to draw. Names of all layers are available at the 'diagFileLayersNames' output
←	outOrigin	Point2D&			Location of the origin from DXF on 'outImage'
←	outImage	Image&			Output image
🔍	diagFileLayersNames	Array<String>&			Names of all layers in DXF file

Remarks

Partial Support

This filter offers only a partial support of DXF files. Notably, *Polyline* and *MText* objects will have to be converted to *2D Polyline*, *Line* or *Text* objects for them to be displayed. Also, SHX files are not supported.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Platform support

This operation is only supported on the Microsoft Windows operating system.

LoadImage_FromWebsite

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Loads a JPG image from a website.

Syntax

```
void avl::LoadImage_FromWebsite
(
 const atl::String& inAddress,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inAddress	const String&		
→	inLogin	Optional<const String&>	NIL	Login for Basic authorization
→	inPassword	Optional<const String&>	NIL	Password for Basic authorization
←	outImage	Image&		Output image

LoadPoint3DGrid

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Loads entities from a file of one of available types as an array of points in 3D.

Syntax

```
void avl::LoadPoint3DGrid
(
 const atl::File& inFile,
 avl::Point3DFileFormat::Type inFileFormat,
 bool inRemoveDuplicates,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
→	inFileFormat	Point3DFileFormat::Type		
→	inRemoveDuplicates	bool	False	Filter will remove duplicate points in point clouds created from STL files.
←	outPoint3DGrid	Point3DGrid&		

Description

The operation loads an grid of points from a file in one of the standard 3D file formats. Currently the filter supports the following formats:

- STL (*.stl),
- PLY (*.ply).
- PCD (*.pcd).

PLY (**Polygon File Format**) also known as the **Stanford Triangle Format** is a format for storing graphical objects described as a collection of polygons. Both ASCII and binary (big-endian and little-endian) versions are supported. Please note that only vertex coordinates can be loaded. Other elements and properties are omitted.

STL (**STereoLithography**) is a file format commonly used in the stereolithography CAD software. Only binary STL is supported.

PCD (**Point Cloud Data**) is a file format for storing point cloud data.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Dimensions x, y and z should have 1 element.
DomainError	Invalid point dimensions in the PCD file - no x, y, z coordinates.
DomainError	Unknown file format in LoadPoint3DGrid.
IoError	An error occurred when mapping the PCD file.
IoError	An error occurred when unmapping the PCD file.
IoError	Error during reading compressed binary file.
IoError	Error during searching for the data section.
IoError	Inconsistent dimensions in PCD file.
IoError	Inconsistent number of parameters in PCD file.
IoError	Inconsistent point definition in PCD file.
IoError	Loading Point3DGrid failed. Too many vertex properties.
IoError	Size of decompressed data does not match with the size stored in the header of PCD file.
IoError	The PCD file is corrupted. The file is is smaller than expected.
IoError	Too few elements in a header entry.
IoError	Too large data type of vertices.
IoError	Too large height.
IoError	Too large width.
IoError	Too many elements of dimension.
IoError	Too many points in PCD file.
IoError	Unable to read PCD file.
IoError	Unknown data type in PCD file
IoError	Unrecognized vertex type.
IoError	Wrong order of header entries in the PCD file.
IoError	Wrong PLY file format. End of header not found.
IoError	Wrong PLY file format. Invalid element definition.
IoError	Wrong PLY file format. Invalid file signature.
IoError	Wrong PLY file format. Invalid format definition.
IoError	Wrong PLY file format. Invalid vertex data.
IoError	Wrong PLY file format. Invalid vertex definition.
IoError	Wrong PLY file format. Invalid vertex property definition.
IoError	Wrong PLY file format. Invalid vertex property type.
IoError	Wrong PLY file format. No vertices found.
IoError	Wrong PLY file format. Unrecognized data encoding.
IoError	Wrong type signature in PCD file.

LoadPoint3DGridWithImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Loads entities from a file of one of available types as an array of points in 3D and an image. Assumes an ordered rectangular grid with no holes.

Syntax

```
void avl::LoadPoint3DGridWithImage
(
 const atl::File& inFile,
 avl::Point3DFileFormat::Type inFileFormat,
 atl::Optional<int> inImageWidth,
 atl::Optional<int> inImageHeight,
 avl::Point3DGrid& outPoint3DGrid,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inFile	const File&			
→	inFileFormat	Point3DFileFormat::Type			
→	inImageWidth	Optional<int>	1 – 65535	NIL	An override for the point cloud width
→	inImageHeight	Optional<int>	1 – 65535	NIL	An override for the point cloud height
←	outPoint3DGrid	Point3DGrid&			
←	outImage	Image&			Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown file format in LoadPoint3DGridWithImage.

LoadSurfaceWithImage

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Loads entities from a file of one of available types as an array of points in 3D and an image. Assumes an unordered grid with possible holes.

Syntax

```
void avl::LoadSurfaceWithImage
(
 const atl::File& inFile,
 avl::Point3DFileFormat::Type inFileFormat,
 const double inXScale,
 const avl::ValueLimits_f64& inXLimits,
 const double inYScale,
 const avl::ValueLimits_f64& inYLimits,
 const double inZOffset,
 const double inZScale,
 avl::PlainType::Type inPointType,
 avl::SurfaceMultipointHeight::Type inMultipointHeight,
 const avl::Pixel& inBackgroundColor,
 avl::Surface& outSurface,
 avl::Image& outImage,
 atl::Optional<double&> outMinX = atl::NIL,
 atl::Optional<double&> outMinY = atl::NIL,
 avl::Region& diagSurfaceValidPointsRegion
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inFile	const File&			
➡	inFileFormat	Point3DFileFormat::Type			
➡	inXScale	const double	0.000001D – ∞	1.0D	
➡	inXLimits	const ValueLimits_f64&			
➡	inYScale	const double	0.000001D – ∞	1.0D	
➡	inYLimits	const ValueLimits_f64&			
➡	inZOffset	const double			
➡	inZScale	const double	0.000001D – ∞	1.0D	
➡	inPointType	PlainType::Type		Real	Type of single surface point Z coordinate
➡	inMultipointHeight	SurfaceMultipointHeight::Type		Mean	Determines the Z coordinate of a surface point created from more than one point
➡	inBackgroundColor	const Pixel&			
⬅	outSurface	Surface&			
⬅	outImage	Image&			Output image
⬅	outMinX	Optional<double&>		NIL	
⬅	outMinY	Optional<double&>		NIL	
🔍	diagSurfaceValidPointsRegion	Region&			Region of locations where the surface points are valid

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinX**, **outMinY**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown file format in LoadSurfaceWithImage.

SavePoint3DGrid

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Saves Point3DGrid in to file in one of the supported formats.

Syntax

```
void avl::SavePoint3DGrid
(
 const atl::File& inFile,
 const avl::Point3DGrid& inPoint3DGrid,
 avl::Point3DFileFormat::Type inFileFormat,
 avl::StreamMode::Type inStreamMode
)
```

Parameters

	Name	Type	Default	Description
➡	inFile	const File&		
➡	inPoint3DGrid	const Point3DGrid&		
➡	inFileFormat	Point3DFileFormat::Type	PLY	
➡	inStreamMode	StreamMode::Type		

Errors

List of possible exceptions:

Error type	Description
DomainError	Unknown file format in SavePoint3DGrid.
DomainError	Unsupported file format in SavePoint3DGrid.
IoError	Incorrect float conversion.
IoError	Wrong PLY file format. Invalid vertex property type.

109. Histogram IO

Table of content:

- LoadHistogram
- SaveHistogram

LoadHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Loads serialized Histogram object from AVDATA file.

Syntax

```
void avl::LoadHistogram
(
 const atl::File& inFilename,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outHistogram	Histogram&		Deserialized output Histogram

SaveHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Saves serialized Histogram object as AVDATA file.

Syntax

```
void avl::SaveHistogram
(
 const avl::Histogram& inHistogram,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inHistogram	const Histogram&		Histogram to be serialized
→	inFilename	const File&		Name of the target file

110. Path IO

Table of content:

- LoadPath
- SavePath

LoadPath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads serialized Path object from AVDATA file.

Syntax

```
void avl::LoadPath
(
 const atl::File& inFilename,
 avl::Path& outPath
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outPath	Path&		Deserialized output Path

Also in AVL Lite

SavePath

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves serialized Path object as AVDATA file.

Syntax

```
void avl::SavePath
(
 const avl::Path& inPath,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Path to be serialized
→	inFilename	const File&		Name of the target file

111. Point3DGrid IO

Table of content:

- LoadPoint3DGridObject
- SavePoint3DGridObject

LoadPoint3DGridObject

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Deserializes a profile from an AVDATA file.

Syntax

```
void avl::LoadPoint3DGridObject
(
 const atl::File& inFilename,
 avl::Point3DGrid& outPoint3DGrid
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outPoint3DGrid	Point3DGrid&		Deserialized output Point3DGrid

SavePoint3DGridObject

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Serializes a profile to an AVDATA file.

Syntax

```
void avl::SavePoint3DGridObject
(
 const avl::Point3DGrid& inPoint3DGrid,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		Point3DGrid to be serialized
→	inFilename	const File&		Name of the target file

112. Profile IO

Table of content:

- LoadProfile
- SaveProfile

LoadProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Deserializes a profile from an AVDATA file.

Syntax

```
void avl::LoadProfile
(
 const atl::File& inFilename,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outProfile	Profile&		Deserialized output Profile

SaveProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Serializes a profile to an AVDATA file.

Syntax

```
void avl::SaveProfile
(
 const avl::Profile& inProfile,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Profile to be serialized
→	inFilename	const File&		Name of the target file

113. Region IO

Table of content:

- LoadRegion
- SaveRegion

LoadRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Loads a region from an AVDATA file.

Syntax

```
void avl::LoadRegion
(
 const atl::File& inFilename,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outRegion	Region&		Deserialized output Region

Also in AVL Lite

SaveRegion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Saves a serialized region object to an AVDATA file.

Syntax

```
void avl::SaveRegion
(
 const avl::Region& inRegion,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Region to be serialized
→	inFilename	const File&		Name of the target file

114. Surface IO

Table of content:

- LoadSurface
- SaveSurface

LoadSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Deserializes a surface from an AVDATA file.

Syntax

```
void avl::LoadSurface
(
 const atl::File& inFilename,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outSurface	Surface&		Deserialized output Surface

SaveSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Serializes a surface to an AVDATA file.

Syntax

```
void avl::SaveSurface
(
 const avl::Surface& inSurface,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Surface to be serialized
→	inFilename	const File&		Name of the target file

115. Image Vector Transforms

Table of content:

- MeasurePixelVectors
- NormalizePixelVectors
- PixelVectorDirAndPresence
- ResizePixelVectors
- RotatePixelVectors

MeasurePixelVectors

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes gradient magnitudes of an image.

Syntax

```
void avl::MeasurePixelVectors
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 2×uint8, 2×uint16, 2×int8, 2×int16, 2×int32, 2×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in MeasurePixelVectors.
DomainError	Not supported inImage pixel format in MeasurePixelVectors. Supported formats: 2xUInt8, 2xUInt16, 2xInt8, 2xInt16, 2xInt32, 2xReal.

NormalizePixelVectors

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Adjusts gradient angles to a given range.

Syntax

```
void avl::NormalizePixelVectors
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::GradientAngleRange::Type inAngleRange,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inAngleRange	GradientAngleRange::Type		
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 2×uint8, 2×uint16, 2×int8, 2×int16, 2×int32, 2×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in NormalizePixelVectors.
DomainError	Not supported inImage pixel format in NormalizePixelVectors. Supported formats: 2xUInt8, 2xUInt16, 2xInt8, 2xInt16, 2xInt32, 2xReal.

PixelVectorDirAndPresence

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes gradient orientations of an image.

Syntax

```
void avl::PixelVectorDirAndPresence
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 2×uint8, 2×uint16, 2×int8, 2×int16, 2×int32, 2×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in PixelVectorDirAndPresence.
DomainError	Not supported inImage pixel format in PixelVectorDirAndPresence. Supported formats: 2xUInt8, 2xUInt16, 2xInt8, 2xInt16, 2xInt32, 2xReal.

ResizePixelVectors

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Rescales an image treating pixels as vectors.

Syntax

```
void avl::ResizePixelVectors
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inVectorLength,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inImage	const Image&			Input image
→	inRoi	Optional<const Region&>		NIL	Region of interest
→	inVectorLength	const float	0.0 – ∞	255.0f	Desired vector length after normalization
←	outImage	Image&			Rescaled image

Description

The filter treats pixels as a vector (each channel value as a coordinate). The operation scales pixels values to desired vector length:

$$||Pixel|| = \sqrt{Pixel.X^2 + Pixel.Y^2 + Pixel.Z^2 + Pixel.W^2}$$
$$Pixel.X = \frac{Pixel.X}{||Pixel||} \cdot inVectorLength$$
$$Pixel.Y = \frac{Pixel.Y}{||Pixel||} \cdot inVectorLength$$
$$Pixel.Z = \frac{Pixel.Z}{||Pixel||} \cdot inVectorLength$$
$$Pixel.W = \frac{Pixel.W}{||Pixel||} \cdot inVectorLength$$

Remarks

If a vector length of a pixel from an input image is zero, the output value equals zero.

If computed channel value exceeds its range, it is cut to maximal allowed value. Therefore the resulting vector length can be smaller than desired.

Computed values are rounded down to the next integer for integer pixel types.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in ResizePixelVectors.

See Also

- NormalizeImage – Rescales an image linearly, so that its minimum becomes inNewMinimum and the maximum of the remaining pixels becomes inNewMaximum.

RotatePixelVectors

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Rotates image gradients.

Syntax

```
void avl::RotatePixelVectors
(
 const avl::Image& inImage,
 atl::Optional<const avl::Region&> inRoi,
 const float inAngle,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inAngle	const float		
←	outImage	Image&		Output image

Requirements

For input **inImage** only pixel formats are supported: 2×uint8, 2×uint16, 2×int8, 2×int16, 2×int32, 2×real.

Read more about pixel formats in Image documentation.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region exceeds an input image in RotatePixelVectors.
DomainError	Not supported inImage pixel format in RotatePixelVectors. Supported formats: 2xUInt8, 2xUInt16, 2xInt8, 2xInt16, 2xInt32, 2xReal.

116. Multilayer Perceptron

Table of content:

- MLP_Init
- MLP_Respond
- MLP_Train

MLP_Init

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates multilayer perceptron model.

Syntax

```
void avl::MLP_Init
(
 atl::Optional<const atl::Array<int>&> inHiddenLayers,
 avl::ActivationFunction::Type inActivationFunction,
 avl::MlpPreprocessing::Type inPreprocessing,
 atl::Optional<int> inRandomSeed,
 int inInputCount,
 int inOutputCount,
 avl::MlpModel& outMlpModel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHiddenLayers	Optional<const Array<int>&>		NIL	Internal structure of MLP network
→	inActivationFunction	ActivationFunction::Type			Type of activation function used to calculate neural response
→	inPreprocessing	MlpPreprocessing::Type			Method of processing input data before learning
→	inRandomSeed	Optional<int>	0 – ∞	NIL	Number used as starting random seed
→	inInputCount	int	1 – ∞	1	MLP network input count
→	inOutputCount	int	1 – ∞	1	MLP network output count
←	outMlpModel	MlpModel&			Initialized MlpModel

Description

Filter initializes and sets structure of the MlpModel.

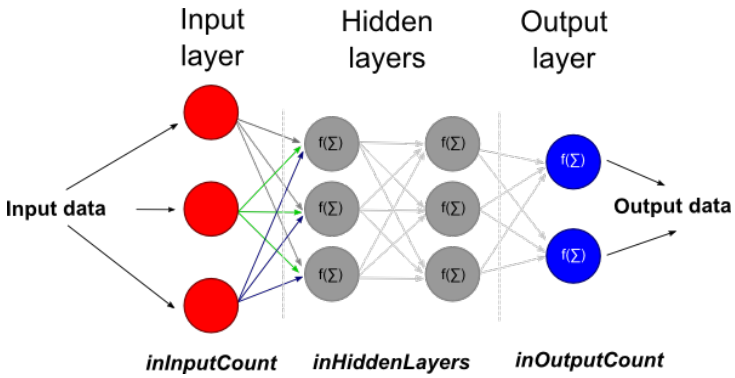

*Image: Internal structure of MlpModel. Function f denotes the **inActivationFunction**.*

Parameter **inHiddenLayers** represents number of neurons in consecutive hidden layers.

The parameter **inActivationFunction** is a function used to calculate internal neuron activation.

The weights of the multilayer perceptron are initialized by a random numbers. Their values depend on **inRandomSeed** value.

Parameters **inInputCount** and **inOutputCount** defines network inputs and outputs count.

See Also

- MLP_Train – Creates and trains multilayer perceptron classifier.
- MLP_Respond – Calculates multilayer perceptron answer.

MLP_Respond

Header: AVL.h
Namespace: avl
Module: FoundationPro

Calculates multilayer perceptron answer.

Syntax

```
void avl::MLP_Respond
(
 const avl::MlpModel& inMlpModel,
 const atl::Array<float>& inInputVector,
 atl::Array<float>& outResponseVector
)
```

Parameters

	Name	Type	Default	Description
→	inMlpModel	const MlpModel&		Trained MlpModel object
→	inInputVector	const Array<float>&		Input vector of features used to calculate classifier response
←	outResponseVector	Array<float>&		Calculated response

Description

The operation calculates response of multilayer perceptron classifier for the input data provided in **inInputVector**.

The parameter **inInputVector** size must be equal to trained MlpModel input count. Input count is set in MLP_Init.

The operation result **outResponseVector** is size of output count provided during MlpModel initializing operation.

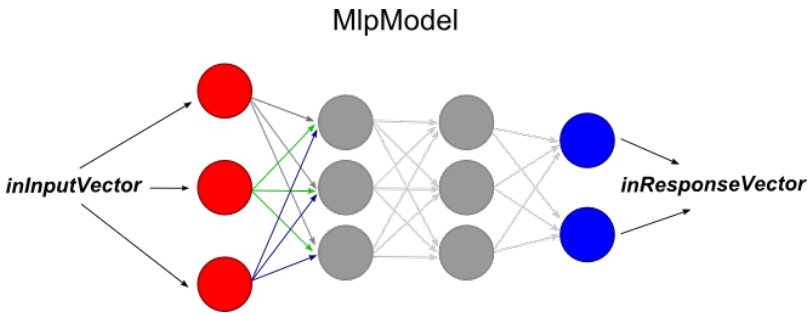

*Image: Visualization of **MLP_Respond** filter.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect or uninitialized MlpModel in MLP_Respond.

See Also

- MLP_Train – Creates and trains multilayer perceptron classifier.
- MLP_Init – Creates multilayer perceptron model.

MLP_Train

Header: AVL.h
Namespace: avl
Module: FoundationPro

Creates and trains multilayer perceptron classifier.

Syntax

```
void avl::MLP_Train
(
 const avl::MlpModel& inMlpModel,
 const atl::Array<atl::Array<float>>& inInputVectorArray,
 const atl::Array<atl::Array<float>>& inResponseVectorArray,
 atl::Optional<const atl::Array<atl::Array<float>>&> inTestInputVectorArray,
 atl::Optional<const atl::Array<atl::Array<float>>&> inTestResponseVectorArray,
 int inIterationCount,
 float inLearningRate,
 float inMomentum,
 atl::Optional<int> inRandomSeed,
 avl::MlpModel& outMlpModel,
 avl::Profile& diagErrorChartLearning,
 avl::Profile& diagErrorChartTesting
)
```

Parameters

	Name	Type	Range	Default	Description
→	inMlpModel	const MlpModel&			Initialized MLP model
→	inInputVectorArray	const Array<Array<float>>&			Array of features used to train model
→	inResponseVectorArray	const Array<Array<float>>&			Array of answers which classifier should get.
→	inTestInputVectorArray	Optional<const Array<Array<float>>&>		NIL	Array of features used to test classifier during training process
→	inTestResponseVectorArray	Optional<const Array<Array<float>>&>		NIL	Array of answers used to test classifier during training process
→	inIterationCount	int	1 – ∞	100	Learning iteration count
→	inLearningRate	float	0.01 – 1.0	1.0f	Learning factor
→	inMomentum	float	0.0 – 1.0	0.01f	Learning momentum ratio
→	inRandomSeed	Optional<int>	0 – ∞	NIL	Number used as starting random seed
←	outMlpModel	MlpModel&			Trained MlpModel
🔍	diagErrorChartLearning	Profile&			Mean error of testing results data during learning process
🔍	diagErrorChartTesting	Profile&			Mean error during learning process

Description

The filter trains multilayer perceptron classifier. The **inInputVectorArray** contains an array of data used to train classifier.

The size of input vector should be constant for each provided input array. Each input vector size must be the same as input count provided in MLP_Init filter during classifier initialization.

The **inResponseVectorArray** contains answer for each data vector provided in **inInputVectorArray**. Size of all response vectors should be the same and equal to output count set in MLP_Init.

The **inLearningRate** determines step size during following function gradient. Too big step size may cause miss of optimization function minimum. Small values may cause learning process too long.

The parameter **inMomentum** defines how learning step results should depend on previous step results.

The **inIterationCount** specifies the number of iterations of the learning process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Different sizes of answer vectors in inResponseVectorArray in MLP_Train.
DomainError	Different sizes of feature vector array and answer vector array on input in MLP_Train.
DomainError	Different sizes of feature vectors in inInputVectorArray in MLP_Train.
DomainError	Empty feature array on input in MLP_Train.
DomainError	Empty inInputVectorArray in MLP_Train
DomainError	Empty inResponseVectorArray in MLP_Train
DomainError	Incorrect or uninitialized MlpModel in MLP_Train.
DomainError	Using uninitialized MlpModel in MLP_Train
DomainError	Wrong size of answer vector in inTestResponseVectorArray in MLP_Train.
DomainError	Wrong size of feature vector in inTestInputVectorArray in MLP_Train.

117. Geometry 2D Normalizations

Table of content:

- NormalizeRectangleOrientation
- NormalizeSegmentOrientation_ByBaseOrientation
- NormalizeSegmentOrientation_ByCoordinate
- NormalizeSegmentOrientation_ByPointDistance
- RemoveInvalidPoints
- ReorientRectangle

NormalizeRectangleOrientation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes orientation of the given rectangle according to parameters.

Syntax

```
void avl::NormalizeRectangleOrientation
(
 const avl::Rectangle2D& inRectangle,
 const float inReferenceAngle,
 const avl::RectangleOrientation::Type inRectangleOrientation,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		Input rectangle
→	inReferenceAngle	const float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	const RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

Read more about In-place Computation.

Description

The operation changes the input rectangle's marked corner so the output rectangle's rotation angle is the lowest possible not lower than **inReferenceAngle** - 90 satisfying the **inRectangleOrientation** parameter at the same time. Some sample parameters configurations are:

- **inReferenceAngle** = 90, **inRectangleOrientation** = Any - the marked corner will have the least y coordinate possible
- **inReferenceAngle** = 0, **inRectangleOrientation** = Any - the marked corner will have the least x coordinate possible
- **inRectangleOrientation** = Horizontal - the output rectangle's width will be not shorter than its height
- **inRectangleOrientation** = Vertical - the output rectangle's height will be not shorter than its width

Examples

NormalizeRectangleOrientation *performed on a sample rectangle with* ***inReferenceAngle*** *= 90 and* ***inRectangleOrientation*** *= Any.*

NormalizeSegmentOrientation_ByBaseOrientation

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes orientation of the given segment according to base orientation.

Syntax

```
void avl::NormalizeSegmentOrientation_ByBaseOrientation
(
 const avl::Segment2D& inSegment,
 const float inBaseOrientation,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inBaseOrientation	const float	0.0f	An angle relative to which angle differences are calculated
←	outSegment	Segment2D&		A segment which orientation is closer to inBaseOrientation

Description

This operation changes the orientation of the **inSegment** segment according to the given angle. The resulting segment has possibly the smallest difference between its orientation and **inBaseOrientation**. In other words, the function returns the same segment as **inSegment** or rotated by 180 degrees - depending on the difference between the orientations.

Examples

Let's consider two cases with the same input segment, but different **inBaseOrientation**. The coordinates of the segment are as follows:

inSegment.Point1.X 99,000

inSegment.Point1.Y 100,000

inSegment.Point2.X 200,000

inSegment.Point2.Y 201,000

1. Let's assume the **inBaseOrientation** to be equal to **90** degrees.

   The orientation of the input segment is 45 degrees, whereas the orientation of the segment rotated by 180 degrees would be 225 degrees. The difference between 90 and 45 degrees is smaller than the one between 90 and 225, so the output segment would be the same as input.

2. Now, let's assume the **inBaseOrientation** to be **180** degrees.

   The orientation of the input segment is still 45 degrees, and the orientation of the segment rotated by 180 degrees is also still 225 degrees. But now, the difference between 90 and 45 degrees is greater than the one between 90 and 225, so the output segment would be rotated by 180 degrees. The vertexes of the output segment would be swapped as follows:

   inSegment.Point2.X 200,000

   inSegment.Point2.Y 201,000

   inSegment.Point1.X 99,000

   inSegment.Point1.Y 100,000

See Also

- SegmentOrientation - Computes the orientation of a segment.
- NormalizeSegmentOrientation_ByPointDistance - Changes orientation of the given segment according to distance to the given point.
- NormalizeSegmentOrientation_ByCoordinate - Changes orientation of the given segment according to coordinates along selected axis.

NormalizeSegmentOrientation_ByCoordinate

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes orientation of the given segment according to coordinates along selected axis.

Syntax

```
void avl::NormalizeSegmentOrientation_ByCoordinate
(
 const avl::Segment2D& inSegment,
 const avl::Axis::Type inAxis,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inAxis	const Axis::Type	X	An axis relative to which coordinates are compared
←	outSegment	Segment2D&		A segment in which the first point will have smaller coordinate along the selected axis

Description

This operation changes the orientation of the **inSegment** segment according to the coordinates of the input segment's vertices. The first point in the **outSegment** will have smaller coordinate along selected axis.

Examples

Let's consider two cases with the same input segment, but different **inAxis**. The coordinates of the segment are as follows:

inSegment.Point1.X 201,000

inSegment.Point1.Y 100,000

inSegment.Point2.X 100,000

inSegment.Point2.Y 199,000

1. Let's assume the **inAxis** to be **X** axis.

   The coordinates along X axis are 201 and 100. Obviously, 100 is smaller than 201, so the resulting segment will have reversed vertices. The coordinates will be as follows:

   inSegment.Point2.X 100,000

   inSegment.Point2.Y 199,000

   inSegment.Point1.X 201,000

   inSegment.Point1.Y 100,000

2. Now, let's assume the **inAxis** to be **Y** axis.

   The coordinates along Y axis are 100 and 199. As in the previous case, 100 is smaller than 199, so the resulting segment will have the same coordinates as **inSegment**.

See Also

NormalizeSegmentOrientation_ByPointDistance

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes orientation of the given segment according to distance to the given point.

Syntax

```
void avl::NormalizeSegmentOrientation_ByPointDistance
(
 const avl::Segment2D& inSegment,
 const avl::Point2D& inReferencePoint,
 avl::Segment2D& outSegment
)
```

Parameters

	Name	Type	Default	Description
→	inSegment	const Segment2D&		
→	inReferencePoint	const Point2D&		A point relative to which distances are measured
←	outSegment	Segment2D&		A segment in which the first point is closer to inReferencePoint

Description

This operation changes the orientation of the **inSegment** segment according to the distance between the input segment's vertices and given **inReferencePoint**. The resulting segment has the first vertex closer to the **inReferencePoint**.

Examples

Let's consider two cases with the same input segment, but different **inReferencePoint**. The coordinates of the segment are as follows:

inSegment.Point1.X 99,000

inSegment.Point1.Y 100,000

inSegment.Point2.X 200,000

inSegment.Point2.Y 201,000

1. Let's assume the **inReferencePoint** to have coordinates **X = 99, Y = 0**.

   The distance between the first vertex of the segment (X = 99, Y = 100) is equal to 100, whereas the distance between the second vertex of the segment (X = 200, Y = 201) is about 225. That means the first vertex is closer to the **inReferencePoint**, so the resulting segment will have the same coordinates as the input segment.

2. Now, let's assume the **inReferencePoint** to have coordinates **X = 300, Y = 201**.

   The distance between the first vertex of the segment (X = 99, Y = 100) is about 225, whereas the distance between the second vertex of the segment (X = 200, Y = 201) is equal to 100. That means the second vertex is closer to **inReferencePoint**, so the resulting segment will have reversed vertices. Their coordinates will be as follows:

   inSegment.Point2.X 200,000

   inSegment.Point2.Y 201,000

   inSegment.Point1.X 99,000

   inSegment.Point1.Y 100,000

Also in AVL Lite

RemoveInvalidPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Removes invalid points from an array (i.e. points with NaN or INF coordinates).

Syntax

```
void avl::RemoveInvalidPoints
(
 const atl::Array<avl::Point2D>& inPoints,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		
←	outPoints	Array<Point2D>&		

Also in AVL Lite

ReorientRectangle

Header: AVL.h
Namespace: avl
Module: FoundationLite

Changes orientation of the given rectangle by multiple of 90 degrees.

Syntax

```
void avl::ReorientRectangle
(
 const avl::Rectangle2D& inRectangle,
 const int inRotationCount,
 avl::Rectangle2D& outRectangle
)
```

Parameters

	Name	Type	Default	Description
→	inRectangle	const Rectangle2D&		Input rectangle
→	inRotationCount	const int	0	Defines by what multiplicity of 90 degrees rectangle orientation should be changed
←	outRectangle	Rectangle2D&		

In-place Processing

This function supports in-place data processing - you can pass the same reference to **inRectangle** and **outRectangle**

PathArrayPoints

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts an array of paths to an array of points.

Syntax

```
void avl::PathArrayPoints
(
 const atl::Array<avl::Path>& inPaths,
 atl::Array<avl::Point2D>& outPoints
)
```

Parameters

	Name	Type	Default	Description
→	inPaths	const Array<Path>&		
←	outPoints	Array<Point2D>&		

PathAverageTurnAngle

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the average absolute turn angle of a path per unit of length.

Syntax

```
void avl::PathAverageTurnAngle
(
 const avl::Path& inPath,
 float& outAverageTurnAngle
)
```

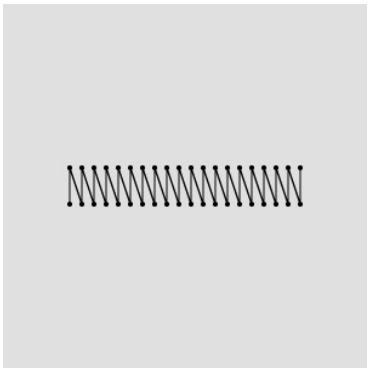
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outAverageTurnAngle	float&		

Description

The operation measures acuteness of the path turn angles. It is computed as the sum of absolute values of path turn angles at path characteristic points divided by length of the path.

Examples



PathAverageTurnAngle *of the sample path equals to 161.57.*

PathAverageTurnAngle *of the sample path equals to 81.16.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input path contains not enough points in PathAverageTurnAngle.

See Also

- PathTurnAngleProfile – Computes the profile of turn angles at characteristic points of a path.

PathBoundingBox

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a path.

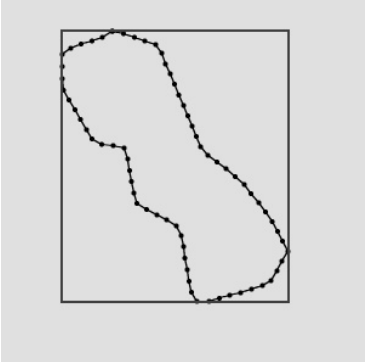
Syntax

```
void avl::PathBoundingBox
(
 const avl::Path& inPath,
 avl::Box& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outBoundingBox	Box&		

Examples



*The resulting **outBoundingBox** box drawn onto the sample path.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathBoundingBox.

See Also

- PathBoundingCircle – Computes the smallest circle enclosing a path.
- RegionBoundingBox – Computes the smallest box containing a region.

PathBoundingBox_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a path; returns NIL if the path is empty.

Syntax

```
void avl::PathBoundingBox_OrNil
(
 const avl::Path& inPath,
 atl::Conditional<avl::Box>& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outBoundingBox	Conditional<Box>&		

PathBoundingCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle enclosing a path.

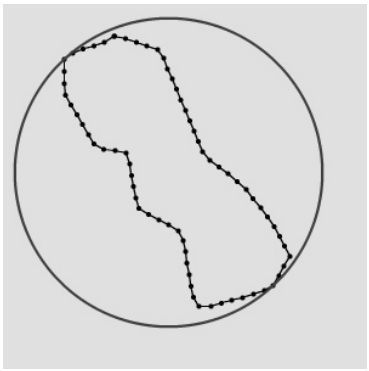
Syntax

```
void avl::PathBoundingCircle
(
 const avl::Path& inPath,
 avl::Circle2D& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outBoundingCircle	Circle2D&		

Examples



*The resulting **outBoundingCircle** circle drawn onto the sample path.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathBoundingCircle.

See Also

- PathBoundingBox – Computes the smallest box containing a path.
- RegionBoundingCircle – Computes the smallest circle enclosing a region.

PathBoundingCircle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle enclosing a path; returns NIL if the path is empty.

Syntax

```
void avl::PathBoundingCircle_OrNil
(
 const avl::Path& inPath,
 atl::Conditional<avl::Circle2D>& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outBoundingCircle	Conditional<Circle2D>&		

PathBoundingParallelogram

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the smallest parallelogram containing a path.

Syntax

```
void avl::PathBoundingParallelogram
(
 const avl::Path& inPath,
 avl::BoundingRectangleFeature::Type inBoundingParallelogramFeature,
 avl::Path& outBoundingParallelogram,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL,
 atl::Optional<float&> outAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inBoundingParallelogramFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding parallelogram will be computed
←	outBoundingParallelogram	Path&		Smallest bounding parallelogram of the input points
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding parallelogram
←	outLongSide	Optional<float&>	NIL	Length of the bounding parallelogram long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding parallelogram short side
←	outAngle	Optional<float&>	NIL	Angle of the bounding parallelogram

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**, **outAngle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathBoundingParallelogram.

PathBoundingRectangle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle containing a path.

Syntax

```
void avl::PathBoundingRectangle
(
 const avl::Path& inPath,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Rectangle2D&		The smallest bounding rectangle of the input path
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Description

The filter computes a rectangle with the smallest possible selected feature that contains all points of the given path. The angle of the resulting rectangle is then normalized as in the NormalizeRectangleOrientation filter.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathBoundingRectangle.

See Also

- NormalizeRectangleOrientation – Changes orientation of the given rectangle according to parameters.

PathBoundingRectangle_FixedAngle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle with the given orientation angle containing a path.

Syntax

```
void avl::PathBoundingRectangle_FixedAngle
(
 const avl::Path& inPath,
 float inAngle,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input path
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathBoundingRectangle_FixedAngle.

PathBoundingRectangle_FixedAngle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle with the given orientation angle containing a path; returns NIL when the path is empty.

Syntax

```
void avl::PathBoundingRectangle_FixedAngle_OrNil
(
 const avl::Path& inPath,
 float inAngle,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input path
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

PathBoundingRectangle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle containing a path; returns NIL when the path is empty.

Syntax

```
void avl::PathBoundingRectangle_OrNil
(
 const avl::Path& inPath,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input path
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

PathCaliperDiameter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the longest and the shortest width of the input path measured as distance between parallel lines containing the whole path.

Syntax

```
void avl::PathCaliperDiameter
(
 const avl::Path& inPath,
 atl::Optional<avl::Segment2D&> outMinDiameter = atl::NIL,
 atl::Optional<float&> outMinDiameterLength = atl::NIL,
 atl::Optional<avl::Segment2D&> outMaxDiameter = atl::NIL,
 atl::Optional<float&> outMaxDiameterLength = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outMinDiameter	Optional<Segment2D&>	NIL	
←	outMinDiameterLength	Optional<float&>	NIL	
←	outMaxDiameter	Optional<Segment2D&>	NIL	
←	outMaxDiameterLength	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinDiameter**, **outMinDiameterLength**, **outMaxDiameter**, **outMaxDiameterLength**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathCaliperDiameter.

PathConvexHull

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest convex shape that contains the given path.

Syntax

```
void avl::PathConvexHull
(
 const avl::Path& inPath,
 avl::Path& outConvexHull
)
```

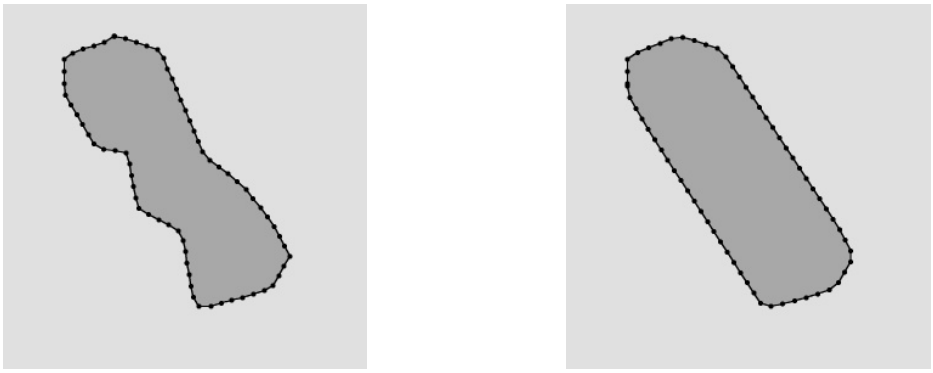
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outConvexHull	Path&		A closed path representing the computed convex hull

Description

The operation computes the smallest of all convex shapes containing the given path.

Examples



PathConvexHull *run on a sample path*

See Also

- PolygonConvexity – Computes the area of a polygon divided by the area of its convex hull.
- RegionConvexHull – Computes the smallest convex region containing the input region.

PathDiameter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Finds the longest segment connecting two characteristic points of a path.

Syntax

```
void avl::PathDiameter
(
 const avl::Path& inPath,
 atl::Optional<avl::Segment2D&> outDiameter,
 atl::Optional<float&> outDiameterLength
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outDiameter	Optional<Segment2D&>		
←	outDiameterLength	Optional<float&>		

Optional Outputs

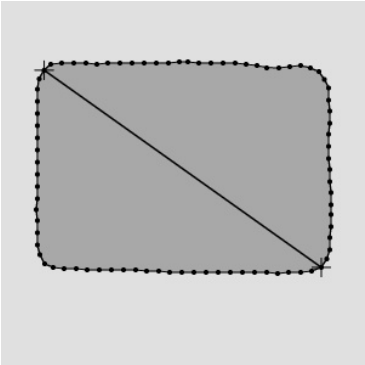
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDiameter**, **outDiameterLength**.

Read more about Optional Outputs.

Description

The operation finds the most distant pair of points within a path and returns the distance between them (**outDiameterLength**) and the segment representing the diameter (**outDiameter**). If there is more than one pair of maximal distance, the returned segment will correspond to one of them. The orientation of the resulting **outDiameter** is always between 0 and 180 degrees.

Examples



*The resulting **outDiameterLength** = 280.0921, **outDiameter** segment was drawn onto the sample path.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathDiameter.

See Also

- RegionDiameter – Computes the longest segment connecting two pixels contained in region and its length.

PathEndpoints

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the two endpoints of a path.

Syntax

```
void avl::PathEndpoints
(
 const avl::Path& inPath,
 avl::Point2D& outFirstPoint,
 avl::Point2D& outLastPoint
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outFirstPoint	Point2D&		
←	outLastPoint	Point2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathEndpoints.

PathLength

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the total length of the input path.

Syntax

```
void avl::PathLength
(
 const avl::Path& inPath,
 float& outLength
)
```

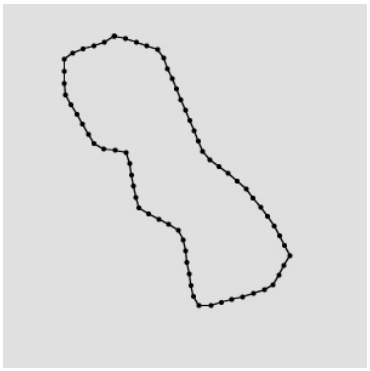
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outLength	float&		

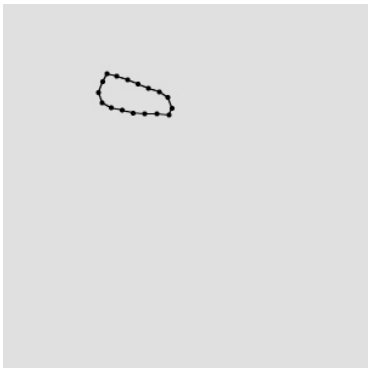
Description

The operation computes the length of the path defined as the sum of the length of the segments it consists of.

Examples



Length of the sample path equals to 633.999.



Length of the sample path equals to 152.002.

See Also

- PathSize – Returns the number of characteristic points on the input path.

PathMassCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of the path points (all, not only characteristic ones).

Syntax

```
void avl::PathMassCenter
(
 const avl::Path& inPath,
 avl::Point2D& outMassCenter
)
```

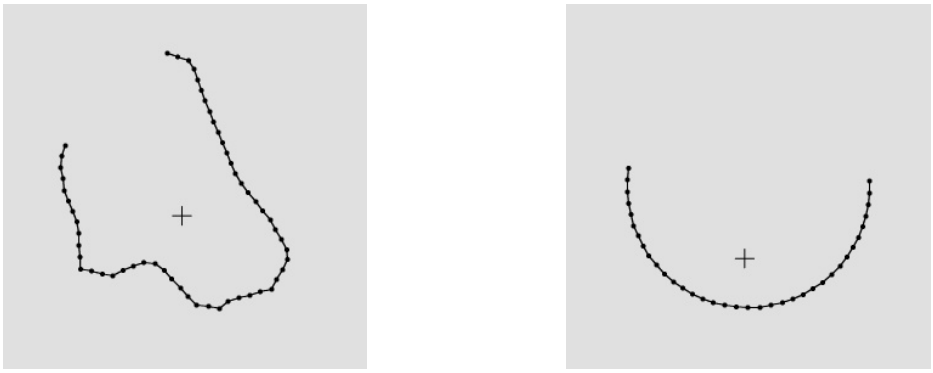
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outMassCenter	Point2D&		

Description

The operation computes the mass center of a path by averaging its points.

Examples



*The resulting **outMassCenter**s drawn onto the sample paths.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathMassCenter.

See Also

- RegionMassCenter – Computes a point with coordinates equal to the average coordinates of the region's pixels.
- PolygonMassCenter – Computes the mass center of polygon.

PathMassCenter_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the average of the path points (all, not only characteristic ones); returns NIL if the path is empty.

Syntax

```
void avl::PathMassCenter_OrNil
(
 const avl::Path& inPath,
 atl::Conditional<avl::Point2D>& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outMassCenter	Conditional<Point2D>&		

Also in AVL Lite

PathSegments

Header: AVL.h
Namespace: avl
Module: FoundationLite

Converts a path to an array of line segments.

Syntax

```
void avl::PathSegments
(
 const avl::Path& inPath,
 atl::Array<avl::Segment2D>& outSegments
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outSegments	Array<Segment2D>&		

PathSelfIntersections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Checks if a path has any self-intersections and computes all of them.

Syntax

```
void avl::PathSelfIntersections
(
 const avl::Path& inPath,
 atl::Array<avl::Point2D>& outSelfIntersections,
 atl::Optional<atl::Array<int>&> outFirstSegmentIndices = atl::NIL,
 atl::Optional<atl::Array<int>&> outSecondSegmentIndices = atl::NIL,
 atl::Optional<bool&> outIsSelfIntersecting = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outSelfIntersections	Array<Point2D>&		
←	outFirstSegmentIndices	Optional<Array<int>&>	NIL	First indices of the segments of the path which generate found intersection points
←	outSecondSegmentIndices	Optional<Array<int>&>	NIL	Second indices of the segments of the path which generate found intersection points
←	outIsSelfIntersecting	Optional<bool&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outFirstSegmentIndices**, **outSecondSegmentIndices**, **outIsSelfIntersecting**.

Read more about Optional Outputs.

PathSize

Header: AVL.h
Namespace: avl
Module: FoundationLite

Returns the number of characteristic points on the input path.

Syntax

```
void avl::PathSize
(
 const avl::Path& inPath,
 int& outSize
)
```

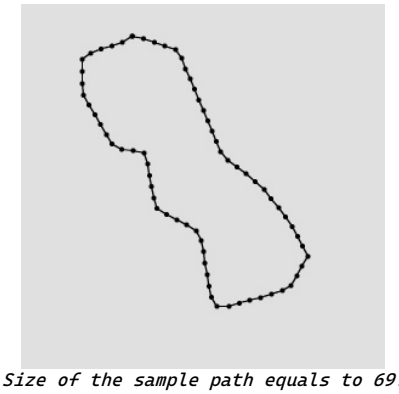
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outSize	int&		

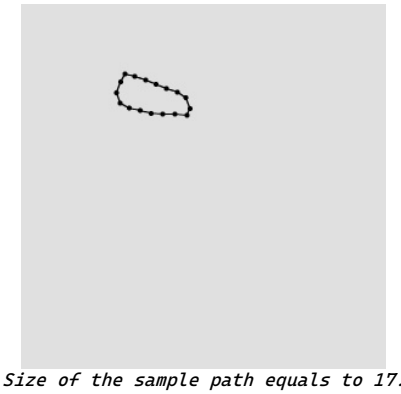
Description

The operation computes the size of the path defined as the number of its characteristic points.

Examples



Size of the sample path equals to 69.



Size of the sample path equals to 17.

See Also

- PathLength – Computes the total length of the input path.

PathTurnAngleLocalMaxima

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the local maxima of the profile of turn angles of a path.

Applications: Detection of feature points related to object corners.

Syntax

```
void avl::PathTurnAngleLocalMaxima
(
 const avl::Path& inPath,
 avl::TurnAngleDirection::Type inAllowedTurnDirection,
 avl::TurnAnglePrecision::Type inResultPrecision,
 const float inMinTurnAngle,
 const float inMinDistance,
 const float inSmoothingStdDev,
 atl::Array<float>& outTurnAngleMaximaIndices,
 atl::Array<avl::Point2D>& outTurnAngleMaximaPoints,
 atl::Array<float>& outTurnAngleMaximaAngles,
 avl::Path& diagSmoothedPath,
 avl::Profile& diagTurnAngleProfile
)
```

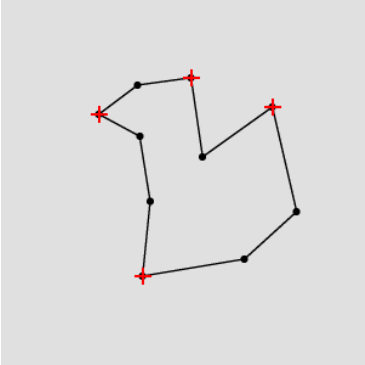
Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inAllowedTurnDirection	TurnAngleDirection::Type		All	Allows to detect only left-turns, only right-turns or both
→	inResultPrecision	TurnAnglePrecision::Type			Switches between pixel-precise or subpixel-precise detection of the found maxima
→	inMinTurnAngle	const float	0.0 – 180.0	30.0f	Minimal value of a relevant angle
→	inMinDistance	const float	0.0 – ∞	0.0f	Minimal distance on the path between two local maxima assuming each path segment has unit length
→	inSmoothingStdDev	const float	0.0 – ∞	0.6f	Standard deviation of the gaussian smoothing applied to the input path
←	outTurnAngleMaximaIndices	Array<float>&			Indices of found local maxima
←	outTurnAngleMaximaPoints	Array<Point2D>&			Found local maxima of turn angle profile of the smoothed input path
←	outTurnAngleMaximaAngles	Array<float>&			Turn angles of found local maxima
🔍	diagSmoothedPath	Path&			Input path smoothed with gaussian kernel
🔍	diagTurnAngleProfile	Profile&			Profile of turn angles at characteristic points of the smoothed input path

Description

The operation computes the profile of turn angles of a path and finds the local maxima of the profile having value at least **inMinTurnAngle**. The **inAllowedTurnDirection** parameter restricts kind of turns taken into consideration (left-turns only, right-turns only or both), while **inResultPrecision** determines the precision of the resulting maxima points. Found maxima have to be at least **inMinDistance** from each other (the distance is measured along the input path assuming each path segment has unit length).

Examples



PathTurnAngleLocalMaxima *run on the sample path with* ***inAllowedTurnDirection*** *= Right*

See Also

- PathTurnAngleMaximum – Finds the maximum of the profile of turn angles of a path.

PathTurnAngleMaximum

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the maximum of the profile of turn angles of a path.

Syntax

```
void avl::PathTurnAngleMaximum
(
 const avl::Path& inPath,
 avl::TurnAngleDirection::Type inAllowedTurnDirection,
 avl::TurnAnglePrecision::Type inResultPrecision,
 float& outMaximumTurnAngleIndex,
 avl::Point2D& outMaximumTurnAnglePoint,
 float& outMaximumTurnAngleAngle
)
```

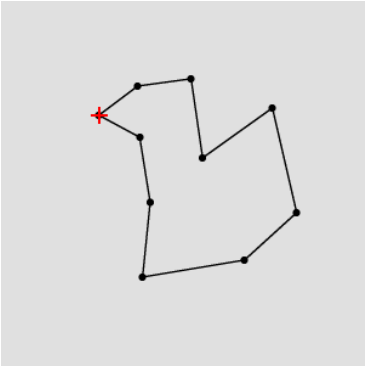
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAllowedTurnDirection	TurnAngleDirection::Type	All	Allows to detect only left-turns, only right-turns or both
→	inResultPrecision	TurnAnglePrecision::Type		Switches between pixel-precise or subpixel-precise detection of the found maximum
←	outMaximumTurnAngleIndex	float&		Index of found maximum
←	outMaximumTurnAnglePoint	Point2D&		Found point of a path with maximum turn angle
←	outMaximumTurnAngleAngle	float&		Maximal turn angle of the input path

Description

The operation computes the profile of turn angles of a path and finds the maximum of the profile. The **inAllowedTurnDirection** parameter restricts kind of turns taken into consideration (left-turns only, right-turns only or both), while **inResultPrecision** determines the precision of the resulting maximum point.

Examples



PathTurnAngleMaximum *run on the sample path with* ***inAllowedTurnDirection*** *= Right*

Errors

List of possible exceptions:

Error type	Description
DomainError	Path with no turn angle on input in PathTurnAngleMaximum.

See Also

- PathTurnAngleLocalMaxima – Finds the local maxima of the profile of turn angles of a path.

PathTurnAngleMaximum_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the maximum of the profile of turn angles of a path; returns NIL if the path has no turn angles.

Syntax

```
void avl::PathTurnAngleMaximum_OrNil
(
 const avl::Path& inPath,
 avl::TurnAngleDirection::Type inAllowedTurnDirection,
 avl::TurnAnglePrecision::Type inResultPrecision,
 atl::Conditional<float>& outMaximumTurnAngleIndex,
 atl::Conditional<avl::Point2D>& outMaximumTurnAnglePoint,
 atl::Conditional<float>& outMaximumTurnAngleAngle
)
```

Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
→	inAllowedTurnDirection	TurnAngleDirection::Type	All	Allows to detect only left-turns, only right-turns or both
→	inResultPrecision	TurnAnglePrecision::Type		Switches between pixel-precise or subpixel-precise detection of the found maximum
←	outMaximumTurnAngleIndex	Conditional<float>&		Index of found maximum
←	outMaximumTurnAnglePoint	Conditional<Point2D>&		Found point of a path with maximum turn angle
←	outMaximumTurnAngleAngle	Conditional<float>&		Maximal turn angle of the input path

PathTurnAngleProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the profile of turn angles at characteristic points of a path.

Syntax

```
void avl::PathTurnAngleProfile
(
 const avl::Path& inPath,
 avl::Profile& outTurnAngleProfile
)
```

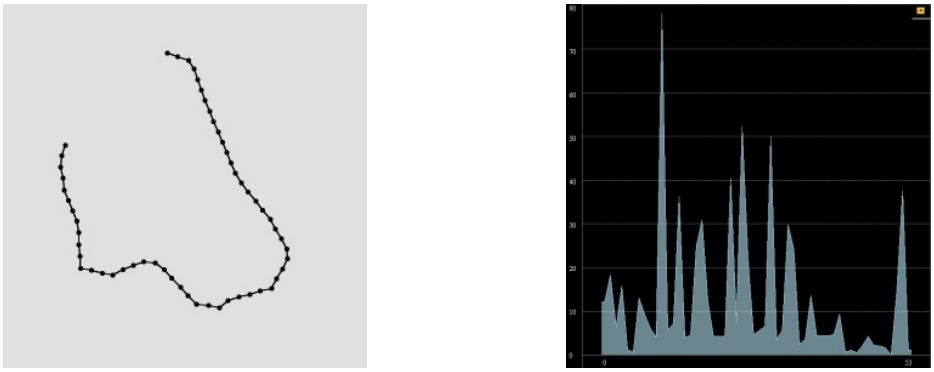
Parameters

	Name	Type	Default	Description
→	inPath	const Path&		Input path
←	outTurnAngleProfile	Profile&		

Description

The operation iterates over the characteristic points of the **inPath** and computes the absolute value of path turn angle at each one. The resulting **outTurnAngleProfile** profile consists of the angles computed at consecutive points of the path.

Examples



PathTurnAngleProfile *run on the sample path*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input path contains a pair of equal consecutive points in PathTurnAngleProfile.

See Also

- PathAverageTurnAngle – Computes the average absolute turn angle of a path per unit of length.

PathEditDistance

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the edit distance between the input paths.

Syntax

```
void avl::PathEditDistance
(
 const avl::Path& inOldPath,
 const avl::Path& inNewPath,
 int& outAdditions,
 int& outRemovals,
 int& outEditions,
 atl::Optional<avl::CoordinateSystem2D&> outAlignment = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outOldCommonPoints = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outNewCommonPoints = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outAddedPoints = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outRemovedPoints = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outOldEditedPoints = atl::NIL,
 atl::Optional<atl::Array<avl::Point2D>&> outNewEditedPoints = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inOldPath	const Path&		
→	inNewPath	const Path&		
←	outAdditions	int&		
←	outRemovals	int&		
←	outEditions	int&		
←	outAlignment	Optional<CoordinateSystem2D&>	NIL	
←	outOldCommonPoints	Optional<Array<Point2D>&>	NIL	
←	outNewCommonPoints	Optional<Array<Point2D>&>	NIL	
←	outAddedPoints	Optional<Array<Point2D>&>	NIL	
←	outRemovedPoints	Optional<Array<Point2D>&>	NIL	
←	outOldEditedPoints	Optional<Array<Point2D>&>	NIL	
←	outNewEditedPoints	Optional<Array<Point2D>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignment**, **outOldCommonPoints**, **outNewCommonPoints**, **outAddedPoints**, **outRemovedPoints**, **outOldEditedPoints**, **outNewEditedPoints**.

Read more about Optional Outputs.

PathToLineDistance

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest distance between a path and a line.

Syntax

```
void avl::PathToLineDistance
(
 const avl::Path& inPath,
 const avl::Line2D& inLine,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inLine	const Line2D&			Input line
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			Minimal distance between input path and input line
←	outConnectingSegment	Optional<Segment2D&>		NIL	Segment connecting input path and input line having minimal length

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathToLineDistance.
DomainError	Indefinite line on input in PathToLineDistance.

PathToLineDistanceProfile

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the profile of distances between a line and the characteristic points of a path.

Syntax

```
void avl::PathToLineDistanceProfile
(
 const avl::Path& inPath,
 const avl::Line2D& inLine,
 float inResolution,
 avl::Profile& outDistanceProfile,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outConnectingSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inLine	const Line2D&			Input line
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistanceProfile	Profile&			Profile of distances between input line and consecutive points of input path
←	outDistances	Optional<Array<float>&>		NIL	Distances between input line and consecutive points of input path
←	outConnectingSegments	Optional<Array<Segment2D>&>		NIL	Segments connecting input line and consecutive points of input path having minimal length

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outConnectingSegments**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite line on input in PathToLineDistanceProfile.

PathToPathDistance

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the minimum distance between two paths.

Syntax

```
void avl::PathToPathDistance
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 avl::PathDistanceMode::Type inPathDistanceMode,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath1	const Path&			First input path
→	inPath2	const Path&			Second input path
→	inPathDistanceMode	PathDistanceMode::Type			Distance measuring method
→	inResolution	float	0.0 – ∞	1.0f	
←	outDistance	float&			Minimal distance between input paths
←	outConnectingSegment	Optional<Segment2D&>		NIL	Segment connecting input paths having minimal length

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

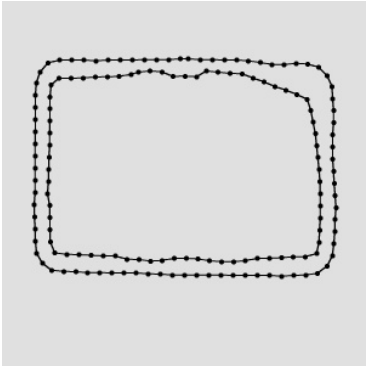
Description

The operation finds the minimal distance between a characteristic point of **inPath1** and path **inPath2**. The distance between a point and a path is computed as follows, depending on the value of **inPathDistanceMode**:

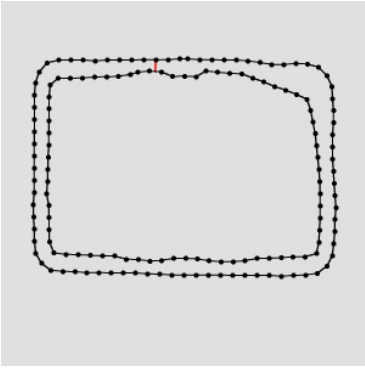
- The distance to nearest characteristic point of **inPath2**, if **inPathDistanceMode** is set to PointToPoint.
- The minimal distance to **inPath2** segments adjacent to the nearest characteristic point of **inPath2** (which is much more precise), if **inPathDistanceMode** is set to PointToSegment.

The operation computes the **outDistance** distance and, additionally, the **outConnectingSegment** line segment corresponding to the result.

Examples



*The **PathToPathDistance** run on the sample paths produces **outDistance** = 9.509.*



*The resulting **outConnectingSegment** drawn onto the input paths.*

Errors

List of possible exceptions:

Error type	Description
DomainError	One or both input paths are empty in PathToPathDistance.

See Also

- PathToPathDistanceProfile – Computes the profile of distances between two paths.

PathToPathDistanceProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the profile of distances between two paths.

Syntax

```
void avl::PathToPathDistanceProfile
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 avl::PathDistanceMode::Type inPathDistanceMode,
 float inResolution,
 avl::Profile& outDistanceProfile,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outConnectingSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath1	const Path&			First input path
→	inPath2	const Path&			Second input path
→	inPathDistanceMode	PathDistanceMode::Type			Distance measuring method
→	inResolution	float	0.0 – ∞	1.0f	
←	outDistanceProfile	Profile&			Profile of distances between second path and consecutive points of first path
←	outDistances	Optional<Array<float>&>		NIL	Distances between second path and consecutive points of first path
←	outConnectingSegments	Optional<Array<Segment2D>&>		NIL	Segments connecting second path and consecutive points of first path having minimal length

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outConnectingSegments**.

Read more about Optional Outputs.

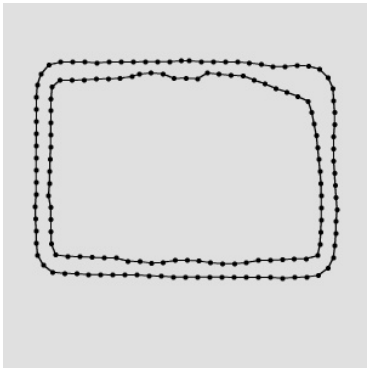
Description

The operation iterates over characteristic points of **inPath1** and at each point computes the distance from this point to **inPath2**. The distance is computed as follows, depending on the value of **inPathDistanceMode**:

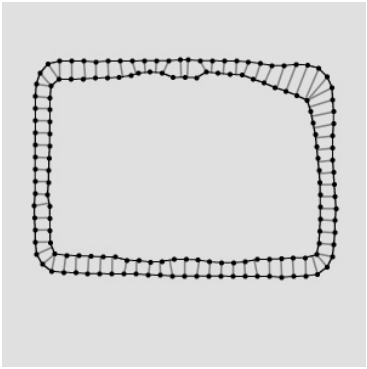
- The distance to nearest characteristic point of **inPath2**, if **inPathDistanceMode** is set to PointToPoint.
- The minimal distance to **inPath2** segments adjacent to the nearest characteristic point of **inPath2** (which is much more precise), if **inPathDistanceMode** is set to PointToSegment.

The operation computes **outDistanceProfile** profile of consecutive distances and, additionally, **outConnectingSegments** array of corresponding line segments.

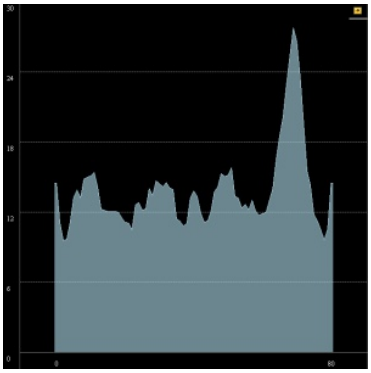
Examples



Sample paths



*The resulting **outConnectingSegments** drawn onto the input paths.*



*The resulting **outDistanceProfile**.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Second input path is empty and first input path is not empty in PathToPathDistanceProfile.

See Also

- PathToPathDistance – Computes the minimum distance between two paths.

PathToPathMaximumDistance

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the distance between the farthest point of the input path from the other path.

Syntax

```
void avl::PathToPathMaximumDistance
(
 const avl::Path& inPath1,
 const avl::Path& inPath2,
 avl::PathDistanceMode::Type inPathDistanceMode,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPath1	const Path&			First input path
→	inPath2	const Path&			Second input path
→	inPathDistanceMode	PathDistanceMode::Type			Distance measuring method
→	inResolution	float	0.0 – ∞	1.0f	
←	outDistance	float&			Distance between farthest point of the input path the other input path
←	outConnectingSegment	Optional<Segment2D&>		NIL	Segment connecting input paths having such distance

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	One or both input paths are empty in PathToPathMaximumDistance.

PathToPointDistance

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest distance between a path and a point.

Syntax

```
void avl::PathToPointDistance
(
 const avl::Point2D& inPoint,
 const avl::Path& inPath,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			Input point
→	inPath	const Path&			Input path
→	inResolution	float	0.0 – ∞	1.0f	
←	outDistance	float&			Minimal distance between input path and input point
←	outConnectingSegment	Optional<Segment2D&>		NIL	Segment connecting input path and input point having minimal length

Optional Outputs

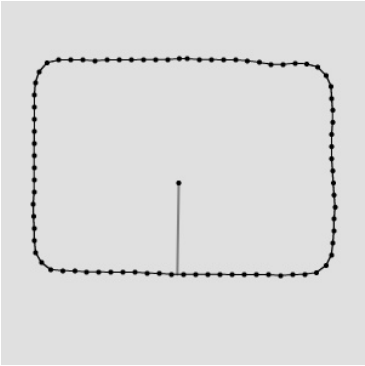
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Description

The operation computes the minimal distance between the **inPoint** and **inPath** and, additionally, the **outConnectingSegment** segment corresponding to the result.

Examples



*The **PathToPointDistance** run on the sample data produces **outDistance** = 75.373.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PathToPointDistance.

See Also

- PathToPointDistanceProfile – Computes the profile of distances between the specified point and the characteristic points of a path.

PathToPointDistanceProfile

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the profile of distances between the specified point and the characteristic points of a path.

Syntax

```
void avl::PathToPointDistanceProfile
(
 const avl::Point2D& inPoint,
 const avl::Path& inPath,
 float inResolution,
 avl::Profile& outDistanceProfile,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<atl::Array<avl::Segment2D>&> outConnectingSegments = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPoint	const Point2D&			Input point
→	inPath	const Path&			Input path
→	inResolution	float	0.0 – ∞	1.0f	
←	outDistanceProfile	Profile&			Profile of distances between input point and consecutive points of input path
←	outDistances	Optional<Array<float>&>		NIL	Distances between input point and consecutive points of input path
←	outConnectingSegments	Optional<Array<Segment2D>&>		NIL	Segments connecting input point and consecutive points of input path

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outConnectingSegments**.

Read more about Optional Outputs.

Description

The operation iterates over characteristic points of **inPath** and at each point computes the distance from this point to **inPoint**. 120. Point3DGrid Features

Table of content:

- Point3DGridHole
- Point3DGridValidPointsRegion

Point3DGridHole

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Finds a biggest hole in a given section of point cloud.

Syntax

```
void avl::Point3DGridHole
(
 const avl::Point3DGrid& inPointGrid,
 atl::Optional<const avl::Region&> inRoi,
 avl::MEstimator::Type inPlaneOutlierSuppression,
 float inClippingFactor,
 int inIterationCount,
 atl::Optional<const avl::Plane3D&> inInitialPlane,
 atl::Conditional<avl::Region>& outHoleRegion,
 atl::Conditional<avl::Point3D>& outHoleCenter,
 avl::Plane3D& outPlane,
 atl::Optional<atl::Array<avl::Point3D>&> outInliers = atl::NIL,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<float&> outSignedDistanceSum = atl::NIL,
 atl::Optional<float&> outDistanceSum = atl::NIL,
 atl::Optional<atl::Array<float>&> outSquaredDistances = atl::NIL,
 atl::Optional<float&> outSquaredDistanceSum = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointGrid	const Point3DGrid&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inPlaneOutlierSuppression	MEstimator::Type			
→	inClippingFactor	float	0.675 – 6.0	2.5f	Multitude of standard deviation within which points are considered inliers
→	inIterationCount	int	0 – ∞	5	Number of iterations of outlier suppressing algorithm
→	inInitialPlane	Optional<const Plane3D&>		NIL	Initial approximation of a plane (if available)
←	outHoleRegion	Conditional<Region>&			Region of the found hole
←	outHoleCenter	Conditional<Point3D>&			Center of the found hole
←	outPlane	Plane3D&			
←	outInliers	Optional<Array<Point3D>&>		NIL	Points matching the computed plane
←	outDistances	Optional<Array<float>&>		NIL	Distances of the input points to a resulting plane
←	outSignedDistanceSum	Optional<float&>		NIL	Sum of signed distances of the input points to a resulting plane
←	outDistanceSum	Optional<float&>		NIL	Sum of distances of the input points to a resulting plane
←	outSquaredDistances	Optional<Array<float>&>		NIL	Squared distances of the input points to a resulting plane
←	outSquaredDistanceSum	Optional<float&>		NIL	Sum of squared distances of the input points to a resulting plane

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outInliers**, **outDistances**, **outSignedDistanceSum**, **outDistanceSum**, **outSquaredDistances**, **outSquaredDistanceSum**.

Read more about Optional Outputs.

Point3DGridValidPointsRegion

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Computes region of locations where points are valid in a points 3D grid and where they are invalid.

Syntax

```
void avl::Point3DGridValidPointsRegion
(
 const avl::Point3DGrid& inPoint3DGrid,
 atl::Optional<const avl::Region&> inRoi,
 avl::Region& outValidPointsRegion,
 avl::Region& outInvalidPointsRegion
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3DGrid	const Point3DGrid&		
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
←	outValidPointsRegion	Region&		Region of locations where points are valid
←	outInvalidPointsRegion	Region&		Region of locations where points are invalid

121. Polygon Features

Table of content:

PolygonArea

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of polygon.

Syntax

```
void avl::PolygonArea
(
 const avl::Path& inPolygon,
 float& outArea
)
```

Parameters

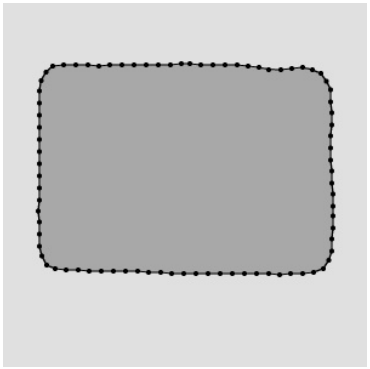
	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outArea	float&		

Description

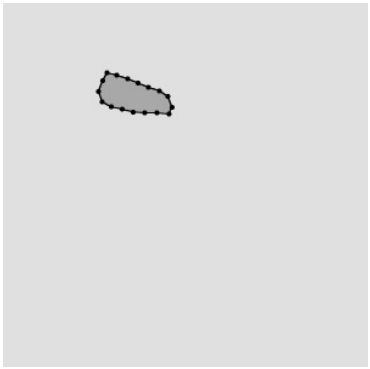
The operation computes the area of a polygon bounded by a closed path. The area is measured in square pixels. As paths in AVS are subpixel-precise, the result may be (and usually is) non-integer.

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



Area of the sample shape equals to 40652.37.



Area of the sample shape equals to 1287.675.

Errors

List of possible exceptions:

Error type	Description
DomainError	Open path on input in PolygonArea.

See Also

- RegionArea – Computes the number of pixels contained in a region.

PolygonCircularity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a polygon divided by the area of a circle having the same feature.

Syntax

```
void avl::PolygonCircularity
(
 const avl::Path& inPolygon,
 const avl::CircularityMeasure::Type inCircularityMeasure,
 float& outCircularity
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
→	inCircularityMeasure	const CircularityMeasure::Type	RadiusPreserving	
←	outCircularity	float&		

Description

Circularity is a measure of similarity of a polygon to the perfect circle. Circular polygons have circularity close to 1.0, while the more elongated the shape is (or contains more holes), the closer to 0.0 is its circularity.

Mathematically, the circularity is calculated as follows:

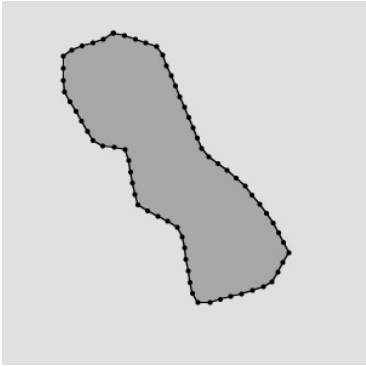
$$Circularity(s) = \frac{Area(s)}{Area(c)}$$

Where **c** denotes a circular polygon having the same feature as input polygon **s**. The feature being considered depends on the **inCircularityMeasure** chosen and it is:

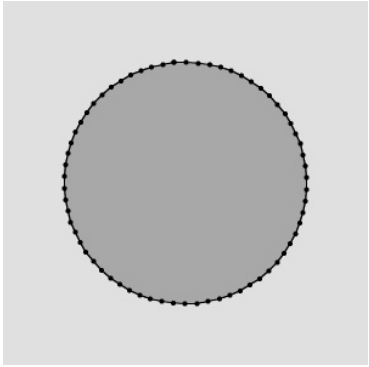
- the minimal bounding circle in case of **BoundingCirclePreserving**
- the perimeter in case of **PerimeterPreserving**
- the radius (maximal distance from mass center to any of the shape points) in case of **RadiusPreserving**

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



*Circularity with **RadiusPreserving** of the sample polygon equals to 0.340.*



*Circularity with **PerimeterPreserving** of the sample polygon equals to 0.998.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonCircularity.
DomainError	Not supported circularity measure in PolygonCircularity.
DomainError	Open path on input in PolygonCircularity.

See Also

- RegionCircularity – Computes the area of a region divided by the area of a circular region having the same feature.
- PolygonConvexity – Computes the area of a polygon divided by the area of its convex hull.
- PolygonElongation – Computes the elongation factor of a polygon (perfect circle has minimal elongation equal 1.0).

PolygonConvexity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a polygon divided by the area of its convex hull.

Syntax

```
void avl::PolygonConvexity
(
 const avl::Path& inPolygon,
 float& outConvexity
)
```

Parameters

	Name	Type	Default	Description
➡	inPolygon	const Path&		
⬅	outConvexity	float&		

Description

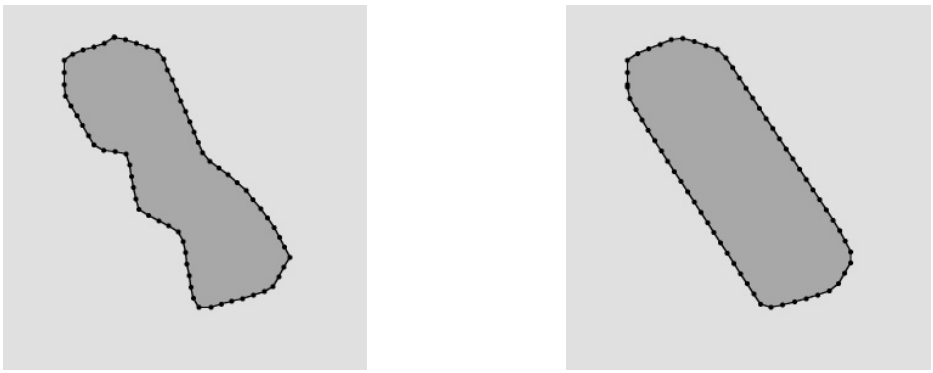
Convexity is a measure of how close a polygon is to being convex. Convex polygons have convexity equal to 1.0, while the more concave the polygon is, the closer to 0.0 is its convexity.

Mathematically, the convexity is calculated as follows:

$$Convexity(s) = \frac{Area(s)}{Area(ConvexHull(s))}$$

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



Area of the sample polygon (on the left) equals to 17529.730, while area of its convex hull (on the right) equals to 20176.250, so the convexity of the polygon equals to 17529.730/20176.250 = 0.867.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonConvexity.
DomainError	Open path on input in PolygonConvexity.

See Also

- RegionConvexity – Computes the area of a region divided by area of its convex hull.
- PathConvexHull – Computes the smallest convex shape that contains the given path.
- PolygonElongation – Computes the elongation factor of a polygon (perfect circle has minimal elongation equal 1.0).
- PolygonCircularity – Computes the area of a polygon divided by the area of a circle having the same feature.

PolygonEllipticAxes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes axes of an ellipse having the same first and second order moments as the given polygon.

Syntax

```
void avl::PolygonEllipticAxes
(
 const avl::Path& inPolygon,
 avl::Segment2D& outMajorAxis,
 avl::Segment2D& outMinorAxis
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outMajorAxis	Segment2D&		
←	outMinorAxis	Segment2D&		

Description

The orientations of the resulting axes are always between 0 and 180 degrees.

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonEllipticAxes.

PolygonElongation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the elongation factor of a polygon (perfect circle has minimal elongation equal 1.0).

Syntax

```
void avl::PolygonElongation
(
 const avl::Path& inPolygon,
 float& outElongation
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outElongation	float&		

Description

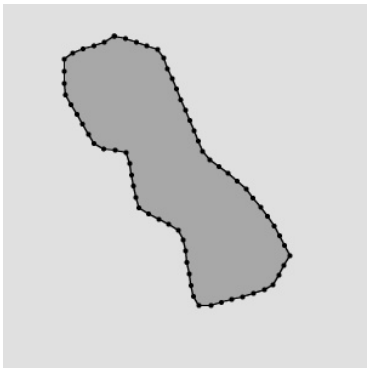
Elongation is a measure of how long the polygon is in relation to its width. The perfect circle has the minimal elongation equal to 1.0, while the upper bound doesn't exist. The operation internally approximates the polygon with an ellipse, and then computes the result as:

$$Elongation(s) = \frac{Length(L)}{Length(S)}$$

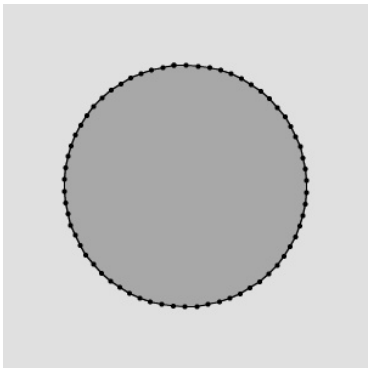
Where **L** denotes the longer axis of the approximating ellipse, and **S** denotes the shorter one.

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



Elongation of the sample polygon equals to 3.283.



Elongation of the sample polygon equals to 1.001.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonElongation.
DomainError	Open path on input in PolygonElongation.

See Also

- PolygonCircularity – Computes the area of a polygon divided by the area of a circle having the same feature.
- RegionElongation – Computes the elongation factor of a region (perfect circle has minimal elongation equal 1.0).

PolygonInscribedCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the circle with the maximal possible area contained in the input polygon.

Syntax

```
void avl::PolygonInscribedCircle
(
 const avl::Path& inPolygon,
 avl::Circle2D& outInscribedCircle
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outInscribedCircle	Circle2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input in PolygonInscribedCircle.
DomainError	Open path on input in PolygonInscribedCircle.

PolygonMassCenter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the mass center of polygon.

Syntax

```
void avl::PolygonMassCenter
(
 const avl::Path& inPolygon,
 avl::Point2D& outMassCenter
)
```

Parameters

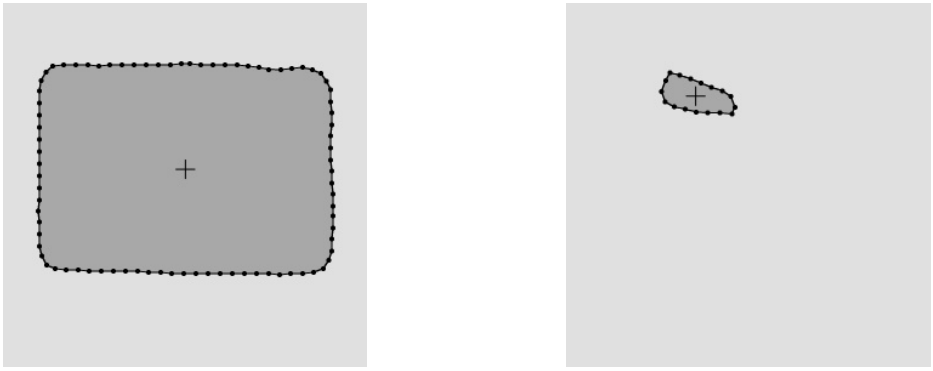
	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outMassCenter	Point2D&		

Description

The operation computes the mass center of a polygon bounded by a closed path.

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



*The resulting **outMassCenter**s drawn onto the sample polygon.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonMassCenter.
DomainError	Open path on input in PolygonMassCenter.

See Also

- PathMassCenter – Computes the average of the path points (all, not only characteristic ones).
- RegionMassCenter – Computes a point with coordinates equal to the average coordinates of the region's pixels.

PolygonMassCenter_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the mass center of polygon; returns Nil for degenerate inputs.

Syntax

```
void avl::PolygonMassCenter_OrNil
(
 const avl::Path& inPolygon,
 atl::Conditional<avl::Point2D>& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outMassCenter	Conditional<Point2D>&		

PolygonOrientation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the polygon orientation as angle with value in range 0.0 - 180.0.

Syntax

```
void avl::PolygonOrientation
(
 const avl::Path& inPolygon,
 float& outOrientationAngle
)
```

Parameters

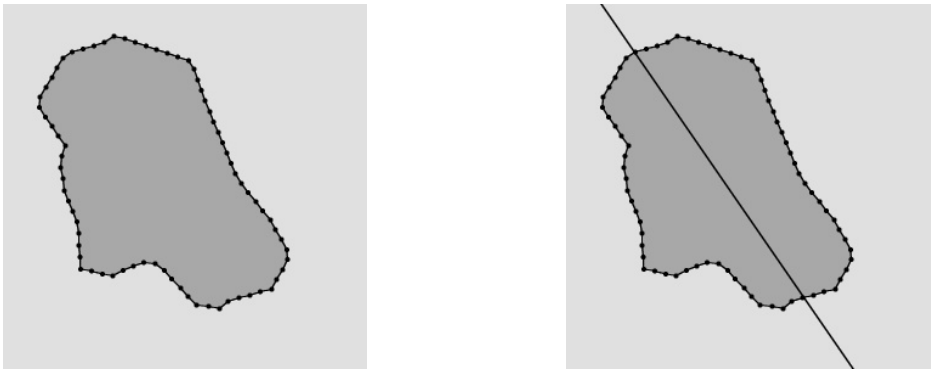
	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outOrientationAngle	float&		

Description

Polygon orientation can be thought of as the direction in which the polygon is oriented. Mathematically it is the angle between X-axis and the line passing through the polygon mass center, that rotation around this line produces the smallest torque.

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Examples



Orientation of the sample region equals to 55.386, which is visualized on the second image by drawing the line of this orientation passing through the mass center of the polygon.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonOrientation.
DomainError	Open path on input in PolygonOrientation.

See Also

- RegionOrientation - Computes the orientation of a region as an angle of value in a proper range.

PolygonRectangularity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a polygon divided by the area of its bounding rectangle.

Syntax

```
void avl::PolygonRectangularity
(
 const avl::Path& inPolygon,
 float& outRectangularity
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outRectangularity	float&		

Description

Note that if the input path is not a valid polygon (i.e. it has at least one self-intersection), the computation may lead to results that are not intuitive.

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonRectangularity.
DomainError	Open path on input in PolygonRectangularity.

PolygonSecondOrderMoments

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Calculates all three second order moments in one pass.

Syntax

```
void avl::PolygonSecondOrderMoments
(
 const avl::Path& inPolygon,
 float& outMoment02,
 float& outMoment11,
 float& outMoment20
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outMoment02	float&		
←	outMoment11	float&		
←	outMoment20	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input in PolygonSecondOrderMoments.
DomainError	Open path on input in PolygonSecondOrderMoments.

PolygonWithNormalizedOrientation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the same polygon but with orientation corresponding to the axes.

Syntax

```
void avl::PolygonWithNormalizedOrientation
(
 const avl::Path& inPolygon,
 avl::Path& outPolygon
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon	const Path&		
←	outPolygon	Path&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Open path on input in PolygonWithNormalizedOrientation.

122. Polygon Relations

Table of content:

- PolygonIntersectionArea_Convex
- PolygonIntersection_Convex
- TestPointArrayInPolygon
- TestPointInPolygon
- TestPolygonConvex
- TestPolygonInPolygon
- TestPolygonsIntersect

PolygonIntersectionArea_Convex

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the intersection area of two convex non-intersecting polygons.

Syntax

```
void avl::PolygonIntersectionArea_Convex
(
 const avl::Path& inPolygon1,
 const avl::Path& inPolygon2,
 float& outIntersectionArea
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon1	const Path&		
→	inPolygon2	const Path&		
←	outIntersectionArea	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Concave polygon on input in PolygonIntersectionArea_Convex.
DomainError	Empty path on input in PolygonIntersectionArea_Convex.
DomainError	Open path on input in PolygonIntersectionArea_Convex.

PolygonIntersection_Convex

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Finds the intersection of two convex non-intersecting polygons.

Syntax

```
void avl::PolygonIntersection_Convex
(
 const avl::Path& inPolygon1,
 const avl::Path& inPolygon2,
 avl::Path& outIntersection
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon1	const Path&		
→	inPolygon2	const Path&		
←	outIntersection	Path&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Concave polygon on input in PolygonIntersection_Convex.
DomainError	Empty path on input in PolygonIntersection_Convex.
DomainError	Open path on input in PolygonIntersection_Convex.

TestPointArrayInPolygon

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests which points lie inside a polygon.

Syntax

```
void avl::TestPointArrayInPolygon
(
 const atl::Array<avl::Point2D>& inPoints,
 const avl::Path& inPolygon,
 atl::Array<bool>& outIsContainedArray,
 atl::Array<avl::Point2D>& outPoints,
 atl::Optional<bool&> outAreAllContained = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inPoints	const Array<Point2D>&		Points which will be tested
→	inPolygon	const Path&		Polygon against which the points will be tested
←	outIsContainedArray	Array<bool>&		
←	outPoints	Array<Point2D>&		Points that are contained
←	outAreAllContained	Optional<bool&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAreAllContained**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty polygon on input in TestPointArrayInPolygon.
DomainError	Open path on input in TestPointArrayInPolygon.

TestPointInPolygon

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point lies inside a polygon.

Syntax

```
void avl::TestPointInPolygon
(
 const avl::Point2D& inPoint,
 const avl::Path& inPolygon,
 bool& outIsContained
)
```

Parameters

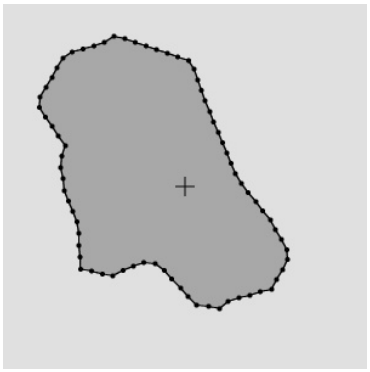
	Name	Type	Default	Description
→	inPoint	const Point2D&		Point the position of which will be tested
→	inPolygon	const Path&		Polygon against which the position will be tested
←	outIsContained	bool&		True if point lies inside the polygon, false otherwise

Description

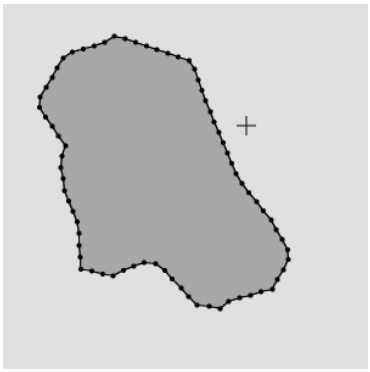
The operation tests if **inPoint** lies inside **inPolygon**.

Due to inaccuracy of floating point representation a point lying extremely close to a path may considered to be on either of the sides of the path or exactly on the path itself.

Examples



TestPointInPolygon *run on the sample data produces the* ***outIsContained*** *= true*



TestPointInPolygon *run on the sample data produces the* ***outIsContained*** *= false*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty polygon on input in TestPointInPolygon.
DomainError	Open path on input in TestPointInPolygon.

See Also

- TestPolygonInPolygon – Tests whether a polygon lies inside another one.

TestPolygonConvex

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether a polygon is convex.

Syntax

```
void avl::TestPolygonConvex
(
 const avl::Path& inPolygon,
 bool& outIsConvex
)
```

Parameters

	Name	Type	Default	Description
➡	inPolygon	const Path&		Input polygon
⬅	outIsConvex	bool&		True if the polygon is convex, false otherwise

TestPolygonInPolygon

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Tests whether a polygon lies inside another one.

Syntax

```
void avl::TestPolygonInPolygon
(
 const avl::Path& inSubPolygon,
 const avl::Path& inPolygon,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
➡	inSubPolygon	const Path&		Polygon the position of which will be tested
➡	inPolygon	const Path&		Polygon against which the position will be tested
⬅	outIsContained	bool&		True if whole polygon lies inside the other one, false otherwise

Description

The operation tests if **inSubPolygon** lies (in its entirety) inside **inPolygon**.

Due to inaccuracy of floating point representation a point lying extremely close to a path may considered to be on either of the sides of the path or exactly on the path itself.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty path on input (inSubPolygon) in TestPolygonInPolygon.
DomainError	Open path on input in TestPolygonInPolygon.

See Also

- TestPointInPolygon – Tests whether a point lies inside a polygon.

TestPolygonsIntersect

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether two polygons share any common point.

Syntax

```
void avl::TestPolygonsIntersect
(
 const avl::Path& inPolygon1,
 const avl::Path& inPolygon2,
 bool& outDoIntersect
)
```

Parameters

	Name	Type	Default	Description
→	inPolygon1	const Path&		First polygon
→	inPolygon2	const Path&		Second polygon
←	outDoIntersect	bool&		True if the polygons share any common point, false otherwise

Errors

List of possible exceptions:

Error type	Description
DomainError	Degenerate polygon on input (fewer than 3 vertices) in TestPolygonsIntersect.
DomainError	Open path on input in TestPolygonsIntersect.

123. Profile Metrics

Table of content:

- ProfileAutocorrelation
- ProfileCorrelation
- ProfileDistance

ProfileAutocorrelation

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the correlation between neighboring sub-profiles of different sizes and infers the most probable period length.

Syntax

```
void avl::ProfileAutocorrelation
(
 const avl::Profile& inProfile,
 int inStart,
 int inMinPeriod,
 int inMaxPeriod,
 int inMinVerifiedLength,
 bool inFlexibleVerification,
 int inMinRepeatCount,
 float inHarmonicHysteresis,
 avl::PeriodPrecisionMethod::Type inPrecisionMethod,
 atl::Array< float >& outAutocorrelationValues,
 float& outPeriod,
 float& outPeriodScore
)
```

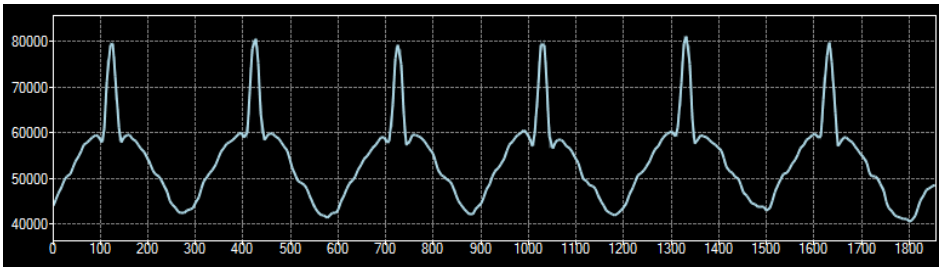
Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inStart	int	0 – ∞		Beginning index of the sub-profile of interest
→	inMinPeriod	int	2 – ∞	2	Minimum period length
→	inMaxPeriod	int	2 – ∞	2	Maximum period length
→	inMinVerifiedLength	int	1 – ∞	1	Minimum number of profile points that verify single period (increases the actual RepeatCount for small periods)
→	inFlexibleVerification	bool			Compensates errors resulting from whole-pixel precision
→	inMinRepeatCount	int	1 – ∞	1	The number of repeats for sufficiently big periods
→	inHarmonicHysteresis	float	0.0 – 1.0	0.05f	Defines how much better must be the period T than T/2, T/3 etc. to be accepted
→	inPrecisionMethod	PeriodPrecisionMethod::Type			Defines if and how sub-point precision is achieved
←	outAutocorrelationValues	Array< float >&			Autocorrelation values for consecutive period values
←	outPeriod	float&			Estimated period length
←	outPeriodScore	float&			Correlation value for the estimated period length

Description

This filter is usually used to find a period within a profile. It tests all possible periods from the range **inMinPeriod** and **inMaxPeriod**. For each candidate period it creates several sub-profiles of that size and computes the normalized correlation between the first one and the others. As the final score, the minimum of the correlations is taken. The number of sub-profiles that is used is determined with the **inMinRepeatCount** and **inMinVerifiedLength** inputs. The latter is used to increase the number of sub-profiles that are used for small period candidates, which often cause false high-scoring periods when used without this parameter. Furthermore, as for any good period of the length T, the periods of the length T * 2, T * 3 etc. also score high, the **inHarmonicHysteresis** input can be used to define the minimum difference between the score of the tested period (T) and its integer partitions (T/2, T/3, ...).

Examples



On this profile the ProfileAutocorrelation filter finds a period of length 302 and score 0.998.

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

This operation is optimized for AVX2 technology.

Errors

List of possible exceptions:

Error type	Description
DomainError	inMinPeriod is larger than inMaxPeriod in ProfileAutocorrelation.
DomainError	inStart + inMinVerifiedLength is larger than the profile size in ProfileAutocorrelation.
DomainError	The range of applicable profile periods is empty in ProfileAutocorrelation.

PROFILE ProfileCorrelation

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the correlation between two sub-profiles.

Syntax

```
void avl::ProfileCorrelation
(
 const avl::Profile& inProfile1,
 int inStart1,
 const avl::Profile& inProfile2,
 int inStart2,
 atl::Optional<int> inLength,
 float& outCorrelation,
 atl::Optional<float&> outCovariance = atl::NIL,
 avl::Profile& diagProfile1,
 avl::Profile& diagProfile2
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile1	const Profile&			First input profile
→	inStart1	int	0 – ∞		Start of the first sub-profile of interest
→	inProfile2	const Profile&			Second input profile
→	inStart2	int	0 – ∞		Start of the second sub-profile of interest
→	inLength	Optional<int>	0 – ∞	NIL	Length of the sub-profiles of interest
←	outCorrelation	float&			Pearson correlation coefficient
←	outCovariance	Optional<float&>		NIL	
🔍	diagProfile1	Profile&			First sub-profile of interest
🔍	diagProfile2	Profile&			Second sub-profile of interest

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCovariance**.

Read more about Optional Outputs.

Hardware Acceleration

This operation is optimized for AVX2 technology.

This operation is optimized for NEON technology.

Errors

List of possible exceptions:

Error type	Description
DomainError	At least two element sub-profiles are required in ProfileCorrelation.
DomainError	Empty profiles on input in ProfileCorrelation.
DomainError	First sub-profile is out of range in ProfileCorrelation.
DomainError	Second sub-profile is out of range in ProfileCorrelation.

PROFILE ProfileDistance

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the [mean] square error between two profiles.

Syntax

```
void avl::ProfileDistance
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 atl::Optional<const avl::Range&> inRange,
 avl::DistanceMeasure::Type inDistanceMeasure,
 float& outDistance
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		First input profile
→	inProfile2	const Profile&		Second input profile
→	inRange	Optional<const Range&>	NIL	
→	inDistanceMeasure	DistanceMeasure::Type		Measure of distance
←	outDistance	float&		Output distance value

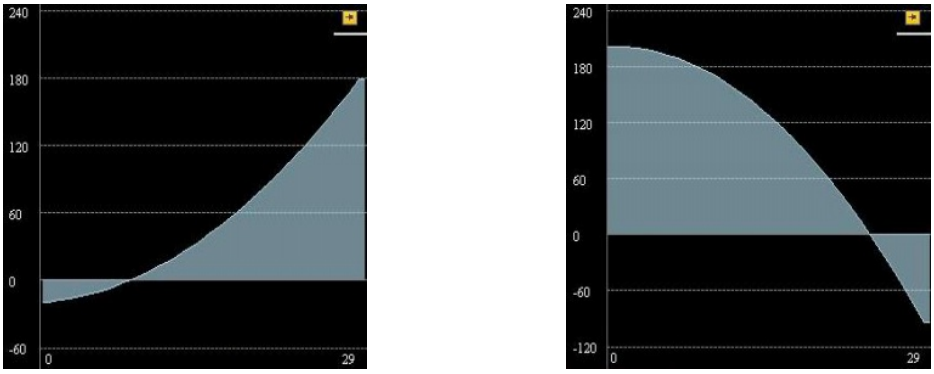
Description

The operation computes the approximate difference between two profiles using the selected distance measure.

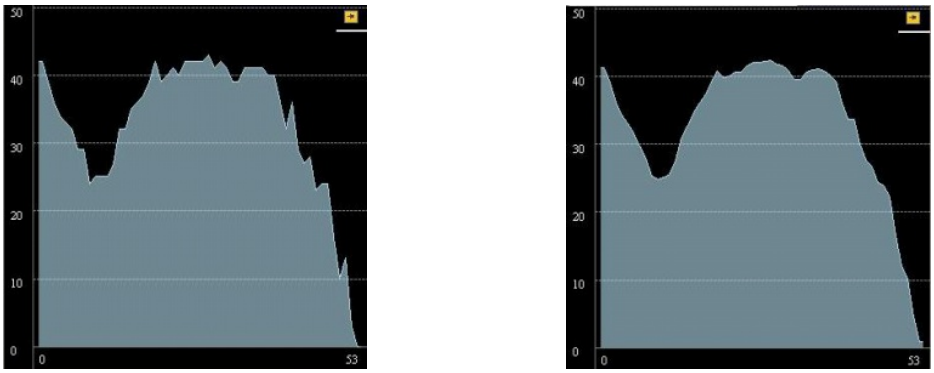
- If the **inDistanceMeasure** is set to **MeanError** then the resulting **outDistance** is the average difference between corresponding values of the profiles.
- If the **inDistanceMeasure** is set to **MeanSquaredError** then the resulting **outDistance** is the average squared difference between corresponding values of the profiles.

The operation requires that the profiles being compared have equal sizes, otherwise an error with appropriate description occurs.

Examples



Mean Squared Error between the sample profiles equals 25245.070.



Mean Error between the sample profiles equals 0.803.

Errors

List of possible exceptions:

Error type	Description
DomainError	DistanceMeasure type not supported in ProfileDistance.
DomainError	Empty profile range in ProfileDistance.
DomainError	Empty profiles on input in ProfileDistance.
DomainError	Input profiles have different X coordinates in ProfileDistance.
DomainError	Range exceeds the input profile in ProfileDistance.
DomainError	Sizes of input profiles differ in ProfileDistance.

124. Profile Features

- ProfileEdges
- ProfileLocalExtrema
- ProfileMaximum
- ProfileMinimum
- ProfileRidges
- ProfileSections
- ProfileSize
- ProfileStripes
- ProfileSum
- ProfileZeroCrossings

ProfileAverage

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the average value of a profile.

Syntax

```
void avl::ProfileAverage
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 float& outAverage
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
←	outAverage	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty profile in ProfileAverage.
DomainError	Empty profile range in ProfileAverage.
DomainError	Range exceeds the input profile in ProfileAverage.

ProfileEdges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the locations at which the profile values raise or fall quickly.

Applications: Can be used for 1D edge detection when the brightness profile is extracted from an image in a non-standard way.

Syntax

```
void avl::ProfileEdges
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 bool inCyclic,
 const avl::EdgeScanParams& inEdgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::ProfileEdge>& outEdges,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inCyclic	bool			
→	inEdgeScanParams	const EdgeScanParams&		EdgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f EdgeTransition: BrightToDark)	Parameters controlling the edge extraction process
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive edges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive edges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outEdges	Array<ProfileEdge>&			Found edges
←	outDistances	Optional<Array<float>&>		NIL	Output distances between consecutive edges
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outResponseProfile**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileEdges.

ProfileLocalExtrema

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the locations at which the values of the input profile are locally highest or lowest.

Syntax

```
void avl::ProfileLocalExtrema
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 const bool inCyclic,
 const avl::ExtremumType::Type inExtremumType,
 avl::ProfileInterpolationMethod::Type inInterpolationMethod,
 const bool inConsiderPlateaus,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::Extremum1D>& outLocalExtrema
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
→	inCyclic	const bool		Indicates whether the last element should be considered a neighbour of the first element
→	inExtremumType	const ExtremumType::Type		Type of extremum to find
→	inInterpolationMethod	ProfileInterpolationMethod::Type	Quadratic4	When interpolation is set to Quadratic each non-plateau extremum is located using a parabola fit
→	inConsiderPlateaus	const bool	True	Indicates whether the result should include centers of plateau extrema
→	inMinValue	Optional<float>	NIL	Minimum value of an extremum
→	inMaxValue	Optional<float>	NIL	Maximum value of an extremum
→	inLocalBlindness	Optional<const LocalBlindness&>	NIL	Defines conditions in which weaker extrema can be detected in the vicinity of stronger ones
←	outLocalExtrema	Array<Extremum1D>&		Extrema of the profile values

Description

The operation returns locations where the profile values are locally extremal, i.e. maximal or minimal, depending on the **inExtremumType** parameter. If the **inConsiderPlateaus** parameter is set to true, the same-value-ranges of the input profile will also be detected. The **inMinValue** and **inMaxValue** parameters control how strong an extremum has to be to be a part of the result. The **inLocalBlindness** parameter allows to have an even better control over the results of the filter. Its fields define a set of conditions in which weaker extrema can be detected in the vicinity of stronger extrema. When e.g. a maximum of value 50 is present at location 35 and another maximum of value 40 is present at location 28, the local blindness with the threshold bigger than 0.8 and the radius not smaller than 7 will suppress the weaker maximum. For minimum, the threshold works as a reciprocal, i.e. under a local blindness with the threshold equal to 0.8 the minimum with value 20 could suppress another minimum with value 26, but not a minimum with value 24. It should be noted that the **inLocalBlindness** parameter has no effect at all when **inExtremumType** is set to **Any**. When some profile values are negative, setting **inLocalBlindness** leads to undefined results.

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileLocalExtrema.

ProfileMaximum

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the highest value of the input profile, its precise location and the corresponding index.

Syntax

```
void avl::ProfileMaximum
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 avl::ProfileInterpolationMethod::Type inInterpolationMethod,
 float& outMaximumPoint,
 atl::Optional<int&> outMaximumIndex = atl::NIL,
 atl::Optional<float&> outMaximumValue = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
→	inInterpolationMethod	ProfileInterpolationMethod::Type	Quadratic4	Profile points' interpolation method
←	outMaximumPoint	float&		Position of highest value with respect to profile's offset and scale
←	outMaximumIndex	Optional<int&>	NIL	Index of highest value
←	outMaximumValue	Optional<float&>	NIL	Highest value

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMaximumIndex**, **outMaximumValue**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty profile in ProfileMaximum.
DomainError	Empty profile range in ProfileMaximum.
DomainError	Range exceeds the input profile in ProfileMaximum.
DomainError	Unsupported interpolation method in ProfileMaximum.

ProfileMinimum

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the lowest value of the input profile, its precise location and the corresponding index.

Syntax

```
void avl::ProfileMinimum
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 avl::ProfileInterpolationMethod::Type inInterpolationMethod,
 float& outMinimumPoint,
 atl::Optional<int&> outMinimumIndex = atl::NIL,
 atl::Optional<float&> outMinimumValue = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
→	inInterpolationMethod	ProfileInterpolationMethod::Type	Quadratic4	Profile points' interpolation method
←	outMinimumPoint	float&		Position of lowest value with respect to profile's offset and scale
←	outMinimumIndex	Optional<int&>	NIL	Index of lowest value
←	outMinimumValue	Optional<float&>	NIL	Lowest value

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinimumIndex**, **outMinimumValue**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty profile in ProfileMinimum.
DomainError	Empty profile range in ProfileMinimum.
DomainError	Range exceeds the input profile in ProfileMinimum.
DomainError	Unsupported interpolation method in ProfileMinimum.

ProfileRidges

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the high or low peaks in the input profile.

Applications: Can be used for 1D ridge detection when the brightness profile is extracted from an image in a non-standard way.

Syntax

```
void avl::ProfileRidges
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 bool inCyclic,
 const avl::RidgeScanParams& inRidgeScanParams,
 float inMinDistance,
 atl::Optional<float> inMaxDistance,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::ProfileRidge>& outRidges,
 atl::Optional<atl::Array<float>&> outDistances = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inCyclic	bool			
→	inRidgeScanParams	const RidgeScanParams&		RidgeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f RidgeWidth: 5 RidgeMargin: 2 MinMagnitude: 5.0f RidgePolarity: Bright)	Parameters controlling the ridge extraction process
→	inMinDistance	float	0.0 – ∞	0.0f	Minimal distance between consecutive ridges
→	inMaxDistance	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive ridges
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker ridges can be detected in the vicinity of stronger ridges
←	outRidges	Array<ProfileRidge>&			Found ridges
←	outDistances	Optional<Array<float>&>		NIL	Output distances between consecutive ridges
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the ridge operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDistances**, **outResponseProfile**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileRidges.

ProfileSections

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds subprofiles whose values fall into the specified range.

Applications: It may also be considered profile thresholding.

Syntax

```
void avl::ProfileSections
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 atl::Optional<float> inMinValue,
 atl::Optional<float> inMaxValue,
 const float inMinSectionWidth,
 atl::Optional<float> inMaxSectionWidth,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<float> inMaxInnerGapWidth,
 atl::Array<avl::ProfileSection>& outSections,
 atl::Conditional<avl::ProfileSection>& outBoundingSection
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inMinValue	Optional<float>		5.0f	Lower bound for profile values
→	inMaxValue	Optional<float>		NIL	Upper bound for profile values
→	inMinSectionWidth	const float	0.0 – ∞	0.0f	Minimal width of the found section
→	inMaxSectionWidth	Optional<float>	0.0 – ∞	NIL	Maximal width of the found section
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive sections
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive sections
→	inMaxInnerGapWidth	Optional<float>	0.0 – ∞	0.0f	Maximal possible gap width between two sections to join them into one
←	outSections	Array<ProfileSection>&			Output profile sections
←	outBoundingSection	Conditional<ProfileSection>&			The smallest section that contains all outSections

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileSections.

ProfileSize

Header: AVL.h
Namespace: avl
Module: FoundationPro

Returns the number of elements in a profile.

Syntax

```
void avl::ProfileSize
(
 const avl::Profile& inProfile,
 int& outSize
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
←	outSize	int&		

ProfileStripes

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds pairs of opposite (raising and falling) edges in the input profile.

Applications: Can be used for 1D stripe detection when the brightness profile is extracted from an image in a non-standard way.

Syntax

```
void avl::ProfileStripes
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 bool inCyclic,
 const avl::StripeScanParams& inStripeScanParams,
 float inMinGapWidth,
 atl::Optional<float> inMaxGapWidth,
 atl::Optional<const avl::LocalBlindness&> inLocalBlindness,
 atl::Array<avl::ProfileStripe>& outStripes,
 atl::Optional<atl::Array<float>&> outGapWidths = atl::NIL,
 atl::Optional<avl::Profile&> outResponseProfile = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inProfile	const Profile&			Input profile
→	inRange	Optional<const Range&>		NIL	
→	inCyclic	bool			
→	inStripeScanParams	const StripeScanParams&		StripeScanParams (ProfileInterpolation: Quadratic4 SmoothingStdDev: 0.6f MinMagnitude: 5.0f MaxInnerEdgeMagnitude: Nil StripePolarity: Bright MinStripeWidth: 0.0f MaxStripeWidth: Nil)	Parameters controlling the stripe extraction process
→	inMinGapWidth	float	0.0 – ∞	0.0f	Minimal distance between consecutive stripes
→	inMaxGapWidth	Optional<float>	0.0 – ∞	NIL	Maximal distance between consecutive stripes
→	inLocalBlindness	Optional<const LocalBlindness&>		NIL	Defines conditions in which weaker edges can be detected in the vicinity of stronger edges
←	outStripes	Array<ProfileStripe>&			Found stripes
←	outGapWidths	Optional<Array<float>&>		NIL	Distances between consecutive stripes
←	outResponseProfile	Optional<Profile&>		NIL	Profile of the edge (derivative) operator response

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outGapWidths**, **outResponseProfile**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileStripes.

ProfileSum

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the sum of profile values.

Syntax

```
void avl::ProfileSum
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 float& outSum
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
←	outSum	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileSum.

ProfileZeroCrossings

Header: AVL.h
Namespace: avl
Module: FoundationPro

Finds the points of a profile at which the profile intersects the x-axis.

Syntax

```
void avl::ProfileZeroCrossings
(
 const avl::Profile& inProfile,
 atl::Optional<const avl::Range&> inRange,
 atl::Array<float>& outZeroCrossings
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inRange	Optional<const Range&>	NIL	
←	outZeroCrossings	Array<float>&		X coordinates of the locations where the profile crosses the y=0 axis

Description

The operation assumes linear interpolation between the profile values and finds precise locations at which the profile crosses the horizontal $y=0$ axis. For the constant profile sections of value 0 only the integer coordinates of the sampling points in the section are returned.

Examples

→	←
inProfile = {-1.0,3.0,0.0,0.0,0.0}	outZeroCrossings = {0.25, 2.0, 3.0, 4.0}

Errors

List of possible exceptions:

Error type	Description
DomainError	Range exceeds the input profile in ProfileZeroCrossings.

RegionArea

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the number of pixels contained in a region.

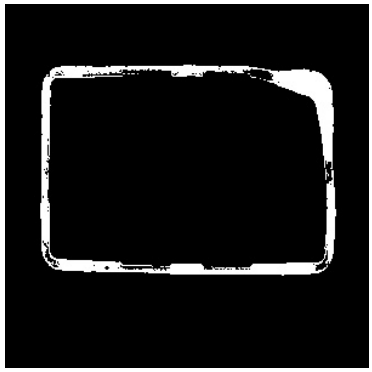
Syntax

```
void avl::RegionArea
(
 const avl::Region& inRegion,
 int& outArea
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outArea	int&		

Examples



Area of the sample region equals to 5567.

Errors

List of possible exceptions:

Error type	Description
DomainError	The area of the region exceeds the capacity of the integer type in RegionArea.

See Also

- PolygonArea – Computes the area of polygon.

RegionBoundingBox

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a region.

Syntax

```
void avl::RegionBoundingBox
(
 const avl::Region& inRegion,
 avl::Box& outBoundingBox
)
```

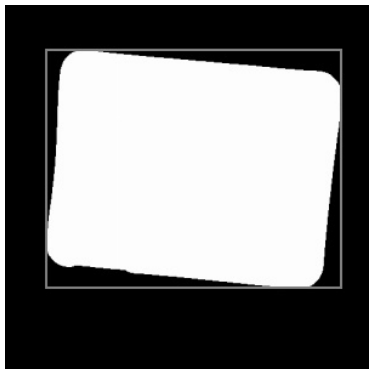
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingBox	Box&		

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



*The resulting **outBoundingBox** box drawn onto the input region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingBox.

See Also

- RegionBoundingCircle – Computes the smallest circle enclosing a region.
- PathBoundingBox – Computes the smallest box containing a path.

RegionBoundingBox_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the smallest box containing a region; returns NIL if the region is empty.

Syntax

```
void avl::RegionBoundingBox_OrNil
(
 const avl::Region& inRegion,
 atl::Conditional<avl::Box>& outBoundingBox
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingBox	Conditional<Box>&		

RegionBoundingCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle enclosing a region.

Syntax

```
void avl::RegionBoundingCircle
(
 const avl::Region& inRegion,
 avl::Circle2D& outBoundingCircle
)
```

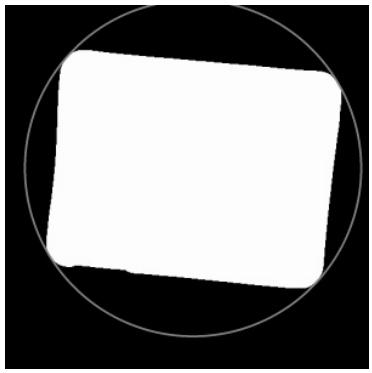
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingCircle	Circle2D&		

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



*The resulting **outBoundingCircle** circle drawn onto the input region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingCircle.

See Also

- RegionBoundingBox – Computes the smallest box containing a region.
- PathBoundingCircle – Computes the smallest circle enclosing a path.

RegionBoundingCircle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest circle enclosing a region; returns NIL if the region is empty.

Syntax

```
void avl::RegionBoundingCircle_OrNil
(
 const avl::Region& inRegion,
 atl::Conditional<avl::Circle2D>& outBoundingCircle
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingCircle	Conditional<Circle2D>&		

RegionBoundingEllipse

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest ellipse enclosing a region.

Syntax

```
void avl::RegionBoundingEllipse
(
 const avl::Region& inRegion,
 avl::Ellipse2D& outBoundingEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingEllipse	Ellipse2D&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingEllipse.

RegionBoundingEllipse_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest ellipse enclosing a region; returns NIL if the region is empty.

Syntax

```
void avl::RegionBoundingEllipse_OrNil
(
 const avl::Region& inRegion,
 atl::Conditional<avl::Ellipse2D>& outBoundingEllipse
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outBoundingEllipse	Conditional<Ellipse2D>&		

RegionBoundingParallelogram

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes the smallest parallelogram containing a region.

Syntax

```
void avl::RegionBoundingParallelogram
(
 const avl::Region& inRegion,
 avl::BoundingRectangleFeature::Type inBoundingParallelogramFeature,
 avl::Path& outBoundingParallelogram,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL,
 atl::Optional<float&> outAngle = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inBoundingParallelogramFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding parallelogram will be computed
←	outBoundingParallelogram	Path&		Smallest bounding parallelogram of the input points
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding parallelogram
←	outLongSide	Optional<float&>	NIL	Length of the bounding parallelogram long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding parallelogram short side
←	outAngle	Optional<float&>	NIL	Angle of the bounding parallelogram

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**, **outAngle**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingParallelogram.

RegionBoundingRectangle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle containing a region.

Syntax

```
void avl::RegionBoundingRectangle
(
 const avl::Region& inRegion,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Rectangle2D&		The smallest bounding rectangle of the input region
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

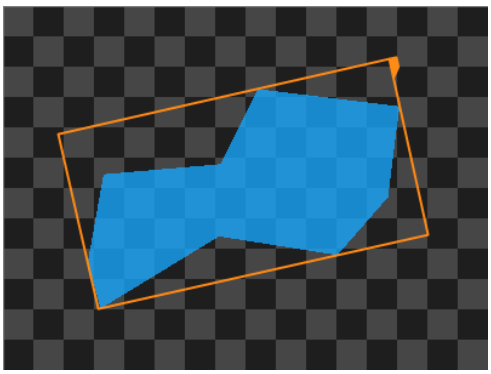
Description

The filter computes a rectangle with the smallest possible selected feature that contains all pixels belonging to the input region. The angle of the resulting rectangle is then normalized as in the NormalizeRectangleOrientation filter.

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



RegionBoundingRectangle *performed on a sample region with* ***inRectangleOrientation*** *set on* ***Vertical***.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingRectangle.

See Also

- NormalizeRectangleOrientation – Changes orientation of the given rectangle according to parameters.

RegionBoundingRectangle_FixedAngle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle with the given orientation angle containing a region.

Syntax

```
void avl::RegionBoundingRectangle_FixedAngle
(
 const avl::Region& inRegion,
 float inAngle,
 avl::Rectangle2D& outBoundingRectangle,
 atl::Optional<avl::Point2D&> outCenter = atl::NIL,
 atl::Optional<float&> outLongSide = atl::NIL,
 atl::Optional<float&> outShortSide = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Rectangle2D&		Smallest bounding rectangle of the input region
←	outCenter	Optional<Point2D&>	NIL	Center of the bounding rectangle
←	outLongSide	Optional<float&>	NIL	Length of the bounding rectangle long side
←	outShortSide	Optional<float&>	NIL	Length of the bounding rectangle short side

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCenter**, **outLongSide**, **outShortSide**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionBoundingRectangle_FixedAngle.

RegionBoundingRectangle_FixedAngle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle with the given orientation angle containing a region; returns NIL if the region is empty.

Syntax

```
void avl::RegionBoundingRectangle_FixedAngle_OrNil
(
 const avl::Region& inRegion,
 float inAngle,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inAngle	float		Expected angle of the resulting rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input region
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

RegionBoundingRectangle_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the smallest rectangle containing a region; returns NIL if the region is empty.

Syntax

```
void avl::RegionBoundingRectangle_OrNil
(
 const avl::Region& inRegion,
 avl::BoundingRectangleFeature::Type inBoundingRectangleFeature,
 float inReferenceAngle,
 avl::RectangleOrientation::Type inRectangleOrientation,
 atl::Conditional<avl::Rectangle2D>& outBoundingRectangle,
 atl::Conditional<avl::Point2D>& outCenter,
 atl::Conditional<float>& outLongSide,
 atl::Conditional<float>& outShortSide
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inBoundingRectangleFeature	BoundingRectangleFeature::Type	MinimalArea	Determines what kind of bounding rectangle will be computed
→	inReferenceAngle	float	0.0f	The middle angle of the valid range of the output rectangle's angle
→	inRectangleOrientation	RectangleOrientation::Type	Horizontal	Orientation of the output rectangle
←	outBoundingRectangle	Conditional<Rectangle2D>&		Smallest bounding rectangle of the input region
←	outCenter	Conditional<Point2D>&		Center of the bounding rectangle
←	outLongSide	Conditional<float>&		Length of the bounding rectangle long side
←	outShortSide	Conditional<float>&		Length of the bounding rectangle short side

RegionCaliperDiameter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the longest and the shortest width of the input region measured as distance between parallel lines containing the whole region.

Syntax

```
void avl::RegionCaliperDiameter
(
 const avl::Region& inRegion,
 atl::Optional<avl::Segment2D&> outMinDiameter = atl::NIL,
 atl::Optional<float&> outMinDiameterLength = atl::NIL,
 atl::Optional<avl::Segment2D&> outMaxDiameter = atl::NIL,
 atl::Optional<float&> outMaxDiameterLength = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outMinDiameter	Optional<Segment2D&>	NIL	
←	outMinDiameterLength	Optional<float&>	NIL	
←	outMaxDiameter	Optional<Segment2D&>	NIL	
←	outMaxDiameterLength	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outMinDiameter**, **outMinDiameterLength**, **outMaxDiameter**, **outMaxDiameterLength**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionCaliperDiameter.

RegionCircularity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a region divided by the area of a circular region having the same feature.

Syntax

```
void avl::RegionCircularity
(
 const avl::Region& inRegion,
 const avl::CircularityMeasure::Type inCircularityMeasure,
 float& outCircularity,
 avl::Circle2D& diagCircle
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inCircularityMeasure	const CircularityMeasure::Type	RadiusPreserving	Which algorithm should be used to compute a circle
←	outCircularity	float&		
🔍	diagCircle	Circle2D&		Computed circle which area was compared.

Description

Circularity is a measure of similarity of a region shape to the perfect circle. Circular regions have circularity close to 1.0, while the more elongated the region is (or contains more holes), the closer to 0.0 is its circularity.

Mathematically, the circularity is calculated as follows:

$$Circularity(r) = \frac{Area(r)}{Area(c)}$$

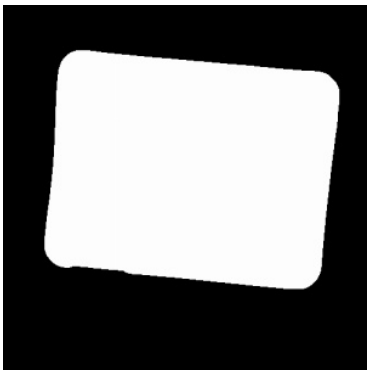
Where **c** denotes a circular region having the same feature as input region **r**. The feature being considered depends on the **inCircularityMeasure** chosen and it is:

- the minimal bounding circle in case of **BoundingCirclePreserving**
- the perimeter in case of **PerimeterPreserving**
- the radius (maximal distance from mass center to any of the region pixels) in case of **RadiusPreserving**

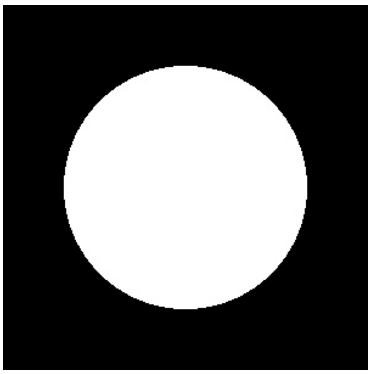
Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



*Circularity with **RadiusPreserving** of the sample region equals to 0.667.*



*Circularity with **PerimeterPreserving** of the sample region equals to 1.000.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionCircularity.
DomainError	Not supported circularity measure in RegionCircularity.

See Also

- RegionConvexity – Computes the area of a region divided by area of its convex hull.
- RegionElongation – Computes the elongation factor of a region (perfect circle has minimal elongation equal 1.0).
- PolygonCircularity – Computes the area of a polygon divided by the area of a circle having the same feature.

RegionComplexity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Calculates how much the input region's perimeter is bigger than the perimeter of a circle of the same area.

Syntax

```
void avl::RegionComplexity
(
 const avl::Region& inRegion,
 float& outComplexity
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outComplexity	float&		

RegionContours

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an array of closed paths corresponding to the contours of the input region.

Syntax

```
void avl::RegionContours
(
 const avl::Region& inRegion,
 const avl::RegionContourMode::Type inContourMode,
 avl::RegionConnectivity::Type inRegionConnectivity,
 atl::Array<avl::Path>& outContours
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inContourMode	const RegionContourMode::Type		
→	inRegionConnectivity	RegionConnectivity::Type	EightDirections	Region connectivity semantics
←	outContours	Array<Path>&		

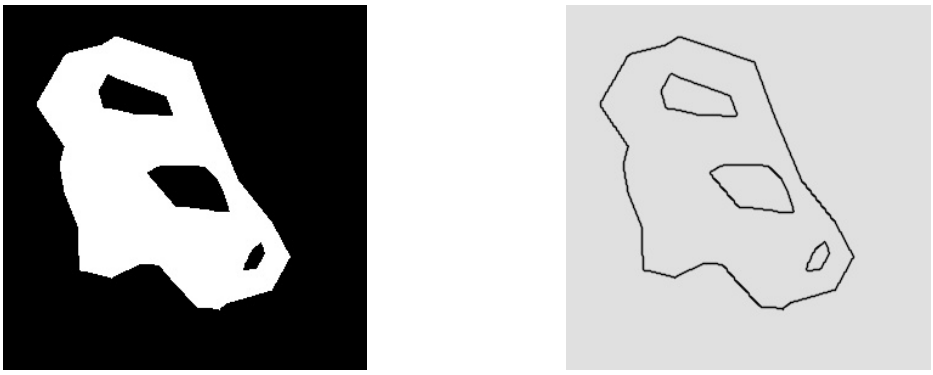
Description

The operation forms an array of paths that, depending on the value of the **inContourMode** parameter:

- Pass through the centers of boundary pixels of the region, if **inContourMode** is set to **PixelCenters**
- Run along the edges of boundary pixels of the region, if **inContourMode** is set to **PixelEdges**

To compute the approximation of the region perimeter length, one can use RegionPerimeterLength filter.

Examples



*The computed **outContours** array drawn onto an empty image.*

See Also

- RegionBoundaries – Removes interior pixels from a region.
- RegionPerimeterLength – Computes the length of the input region perimeter.

RegionConvexity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a region divided by area of its convex hull.

Syntax

```
void avl::RegionConvexity
(
 const avl::Region& inRegion,
 float& outConvexity
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
⬅	outConvexity	float&		

Description

Convexity is a measure of how close a region is to being convex. Convex regions have convexity equal to 1.0, while the more concave the region is, the closer to 0.0 is its convexity.

Mathematically, the convexity is calculated as follows:

$$Convexity(r) = \frac{Area(r)}{Area(ConvexHull(r))}$$

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples

*Area of the sample region (on the left) equals to 2345, while area of its convex hull (on the right) equals to 40357, so the **RegionConvexity** run on the sample region would produce the result 2345/40357 = 0.058 .*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionConvexity.

See Also

- RegionConvexHull – Computes the smallest convex region containing the input region.
- PolygonConvexity – Computes the area of a polygon divided by the area of its convex hull.

RegionDiameter

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the longest segment connecting two pixels contained in region and its length.

Syntax

```
void avl::RegionDiameter
(
 const avl::Region& inRegion,
 atl::Optional<avl::Segment2D&> outDiameter = atl::NIL,
 atl::Optional<float&> outDiameterLength = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outDiameter	Optional<Segment2D&>	NIL	
←	outDiameterLength	Optional<float&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outDiameter**, **outDiameterLength**.

Read more about Optional Outputs.

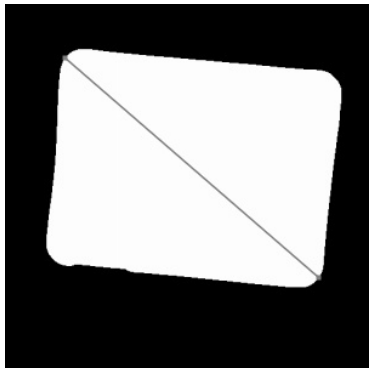
Description

The operation finds the most distant pair of region pixels and returns the distance between them (**outDiameterLength**) and the segment representing the diameter (**outDiameter**). If there is more than one pair of maximal distance, the returned segment will correspond to one of them. The orientation of the resulting **outDiameter** is always between 0 and 180 degrees.

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



*The resulting **outDiameterLength** = 276.4815, **outDiameter** segment was drawn onto the region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionDiameter.

See Also

- RegionPerimeterLength – Computes the length of the input region perimeter.
- PathDiameter – Finds the longest segment connecting two characteristic points of a path.

RegionDirectionalDispersion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Directional standard deviation of the distance of the region's points to the center.

Syntax

```
void avl::RegionDirectionalDispersion
(
 const avl::Region& inRegion,
 const float inOrientation,
 const avl::ProjectionDirection::Type inDirection,
 float& outDispersion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inOrientation	const float		
→	inDirection	const ProjectionDirection::Type	Horizontal	
←	outDispersion	float&		

RegionDispersion

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Calculates how much more the input region's points are dispersed comparing to the points of a circle of the same area.

Syntax

```
void avl::RegionDispersion
(
 const avl::Region& inRegion,
 float& outDispersion
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outDispersion	float&		

RegionEllipticAxes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes axes of an ellipse having the same first and second order moments as the given region.

Syntax

```
void avl::RegionEllipticAxes
(
 const avl::Region& inRegion,
 avl::Segment2D& outMajorAxis,
 avl::Segment2D& outMinorAxis
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outMajorAxis	Segment2D&		
←	outMinorAxis	Segment2D&		

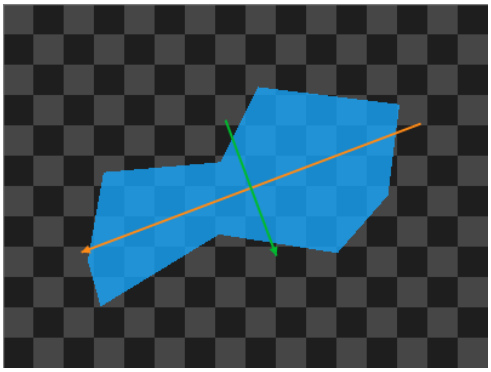
Description

The orientations of the resulting axes are always between 0 and 180 degrees.

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



***RegionEllipticAxes** performed on a sample region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionEllipticAxes.

RegionElongation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the elongation factor of a region (perfect circle has minimal elongation equal 1.0).

Syntax

```
void avl::RegionElongation
(
 const avl::Region& inRegion,
 float& outElongation
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
⬅	outElongation	float&		

Description

Elongation is a measure of how long the shape is in relation to its width. The perfect circle has the minimal elongation equal to 1.0, while the upper bound doesn't exist. The operation internally approximates the region with an ellipse, and then computes the result as:

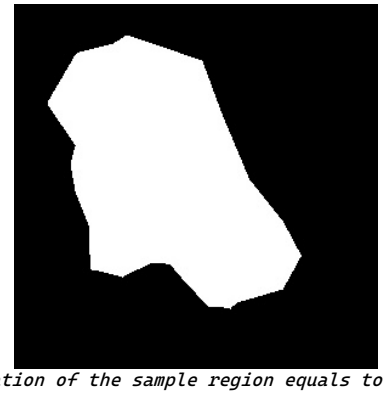
$$Elongation(r) = \frac{Length(L)}{Length(S)}$$

Where **L** denotes the longer axis of the approximating ellipse, and **S** denotes the shorter one.

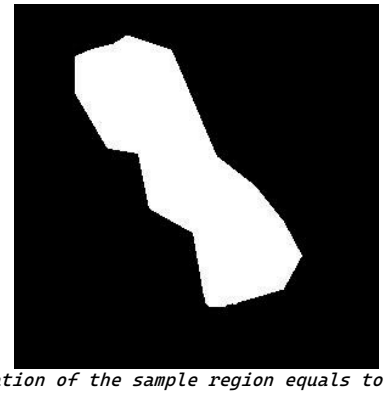
Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



Elongation of the sample region equals to 1.702.



Elongation of the sample region equals to 3.168.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionElongation.

See Also

- RegionCircularity – Computes the area of a region divided by the area of a circular region having the same feature.
- PolygonElongation – Computes the elongation factor of a polygon (perfect circle has minimal elongation equal 1.0).

RegionFeatureValue

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the feature value of the input region.

Syntax

```
void avl::RegionFeatureValue
(
 const avl::Region& inRegion,
 avl::RegionFeature::Type inFeature,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inFeature	RegionFeature::Type		Region feature value to be computed
←	outValue	float&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect RegionFeature in RegionFeatureValue.

RegionHoles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Creates regions of the holes of the input region.

Syntax

```
void avl::RegionHoles
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 int inMinHoleArea,
 atl::Optional<int> inMaxHoleArea,
 atl::Array<avl::Region> & outHoles
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inConnectivity	RegionConnectivity::Type			Region connectivity semantics
→	inMinHoleArea	int	0 – ∞	1	Minimal area of a resulting hole
→	inMaxHoleArea	Optional<int>	0 – ∞	NIL	Maximal area of a resulting hole
←	outHoles	Array<Region> &			

Description

The operation computes regions representing holes of input region. Holes of a region are those connected areas of pixels **not** belonging to the region, that do not touch the boundary of the region frame.

Examples

RegionHoles *run on a sample region.*

See Also

- RegionNumberOfHoles – Computes the number of holes in a region.
- FillRegionHoles – Adds pixels to the input region so that it contains no holes.

RegionHoles_Elastic

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Fills a ridges region with convex basins.

Syntax

```
void avl::RegionHoles_Elastic
(
 const avl::Region& inRegion,
 atl::Optional<const avl::Region&> inRoi,
 int inDistanceThreshold,
 atl::Array<avl::Region>& outBasins
)
```

Parameters

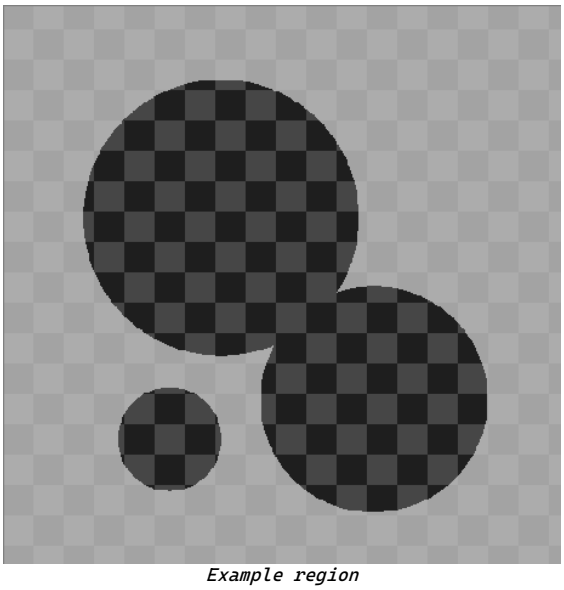
	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
➡	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
➡	inDistanceThreshold	int	5	
⬅	outBasins	Array<Region>&		

Description

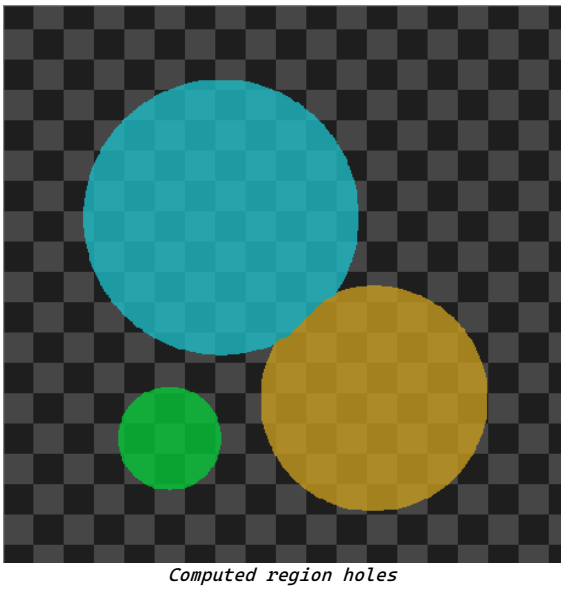
This filter fills a regions holes with convex basins based on a flooding algorithm.

The parameter **inDistanceThreshold** can be used to ignore smaller holes of the input region.

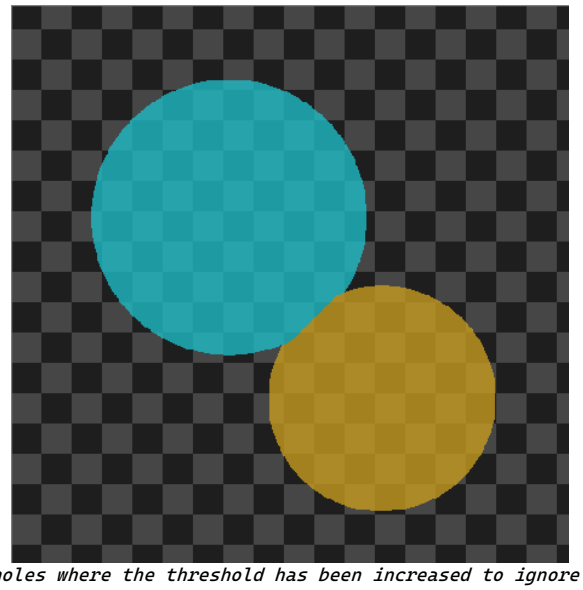
Examples



Example region



Computed region holes



Computed region holes where the threshold has been increased to ignore the smaller hole

See Also

- SegmentImage_Watersheds – Computes dark or bright watershed basins of an image.

RegionInscribedBox

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the largest box contained in a region.

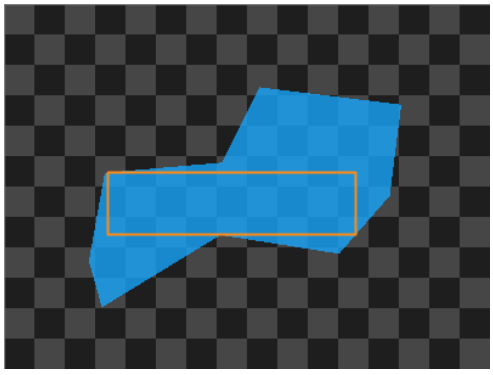
Syntax

```
void avl::RegionInscribedBox
(
 const avl::Region& inRegion,
 const float inMinAspectRatio,
 atl::Optional<float> inMaxAspectRatio,
 const int inMinWidth,
 atl::Optional<int> inMaxWidth,
 const int inMinHeight,
 atl::Optional<int> inMaxHeight,
 atl::Conditional<avl::Box>& outBox
)
```

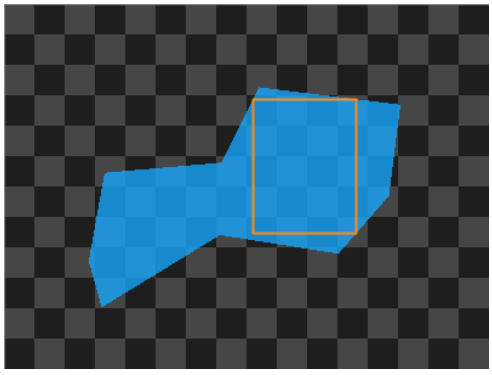
Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inMinAspectRatio	const float	0.0 – ∞	0.0f	Minimal aspect ratio of found box
→	inMaxAspectRatio	Optional<float>	0.0 – ∞	NIL	Maximal aspect ratio of found box (reciprocal of inMinAspectRatio by default)
→	inMinWidth	const int	1 – 65535	1	Minimal width of found box
→	inMaxWidth	Optional<int>	1 – 65535	NIL	Maximal width of found box
→	inMinHeight	const int	1 – 65535	1	Minimal height of found box
→	inMaxHeight	Optional<int>	1 – 65535	NIL	Maximal height of found box
←	outBox	Conditional<Box>&			Found box with largest area

Examples



RegionInscribedBox *performed on a sample region with* ***inMaxAspectRatio*** *= Auto.*



RegionInscribedBox *performed on a sample region with* ***inMaxAspectRatio*** *= 2.0.*

RegionInscribedCircle

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the largest circle contained in a region.

Syntax

```
void avl::RegionInscribedCircle
(
 const avl::Region& inRegion,
 avl::Circle2D& outCircle
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outCircle	Circle2D&		Found circle with largest radius

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionInscribedCircle.

RegionMassCenter

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a point with coordinates equal to the average coordinates of the region's pixels.

Syntax

```
void avl::RegionMassCenter
(
 const avl::Region& inRegion,
 avl::Point2D& outMassCenter,
 atl::Optional<int&> outArea = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outMassCenter	Point2D&		
←	outArea	Optional<int&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outArea**.

Read more about Optional Outputs.

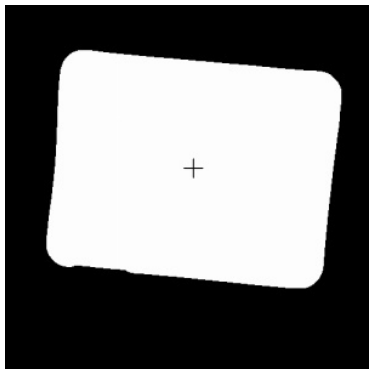
Description

The operation computes the average of all pixel locations contained in a region. Note that the result is a Point2D, not a Location as its coordinates may be not-integer.

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples



*The resulting **outMassCenter** point drawn onto the sample region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input region is empty in RegionMassCenter.

See Also

- PolygonMassCenter – Computes the mass center of polygon.

RegionMassCenter_OrNil

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a point with coordinates equal to the average coordinates of the region's pixels; returns NIL if the region is empty.

Syntax

```
void avl::RegionMassCenter_OrNil
(
 const avl::Region& inRegion,
 atl::Conditional<avl::Point2D>& outMassCenter,
 atl::Optional<atl::Conditional<int>&> outArea = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outMassCenter	Conditional<Point2D>&		
←	outArea	Optional<Conditional<int>&>	NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outArea**.

Read more about Optional Outputs.

RegionMedialAxis

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes an array of paths corresponding to the skeleton of the input region.

Syntax

```
void avl::RegionMedialAxis
(
 const avl::Region& inRegion,
 avl::RegionSkeletonMethod::Type inRegionSkeletonMethod,
 atl::Array<avl::Path>& outSkeletonPaths
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inRegionSkeletonMethod	RegionSkeletonMethod::Type	TwelveConnected	
←	outSkeletonPaths	Array<Path>&		

Description

The operation performs skeletonization presenting result as an array of paths.

Skeleton of a region is a connected set of medial axis of its limbs. It is a useful tool when one is interested only in general structure of a shape and wants to disregard width of its limbs. Two methods are available, depending on the value of **inRegionSkeletonMethod** being chosen:

- **EightConnected**: the input region is thinned as long as the thinning procedure affects it; the structuring elements come from the well known Golay alphabet
- **TwelveConnected**: the input region is thinned also, but the structuring elements being used are slightly larger than in previous method (they consider 12-neighborhood of the given pixel instead of 8-neighborhood). The method comes from the paper of U. Eckhardt and G. Maderlechner "Invariant thinning"

The second method is slower than the first one, but its results look in most cases much better than the first one's results.

This filter is a cousin of SkeletonizeRegion which represents the results as a region instead of an array of paths.

Examples

*The resulting **outSkeletonPaths** paths drawn onto the input region, **inRegionSkeletonMethod** = **TwelveConnected**.*

See Also

- SkeletonizeRegion – Thins a region to its skeleton.

RegionMoment

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes selected second-order moment of a region in regular and normalized (divided by region area) variant.

Syntax

```
void avl::RegionMoment
(
 const avl::Region& inRegion,
 avl::RegionMomentType::Type inMomentType,
 bool inCentral,
 float& outMoment,
 float& outNormMoment
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inMomentType	RegionMomentType::Type		
→	inCentral	bool		
←	outMoment	float&		
←	outNormMoment	float&		

Description

The operation computes the mathematical features of a shape called moments. Those are sums computed as follows:

$$Moment_{2,0}(R) = \sum_{p \in R} p_x^2$$
$$Moment_{1,1}(R) = \sum_{p \in R} p_x p_y$$
$$Moment_{0,2}(R) = \sum_{p \in R} p_y^2$$

The summing is conducted over region pixels, while p_x and p_y denote, accordingly, x and y coordinate of a pixel.

When **inCentral** parameter is set, the region is shifted before computations, so that its mass center is at location (0,0).

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionMoment.
DomainError	Not supported moment type in RegionMoment.

See Also

- ImageMoment – Computes the selected moment of an image in regular and normalized (divided by sum of pixel values) variant.

RegionNumberOfHoles

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the number of holes in a region.

Syntax

```
void avl::RegionNumberOfHoles
(
 const avl::Region& inRegion,
 avl::RegionConnectivity::Type inConnectivity,
 int inMinHoleArea,
 atl::Optional<int> inMaxHoleArea,
 int& outNumberOfHoles
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion	const Region&			Input region
→	inConnectivity	RegionConnectivity::Type			Region connectivity semantics
→	inMinHoleArea	int	0 – ∞	1	Minimal area of a hole
→	inMaxHoleArea	Optional<int>	0 – ∞	NIL	Maximal area of a hole
←	outNumberOfHoles	int&			

Description

The operation computes the number of region holes. Holes of a region are those connected areas of pixels **not** belonging to the region, that do not touch the boundary of the region frame.

Examples

The number of holes in the sample (left) region equals to 3. The holes are presented on the right image.

See Also

- FillRegionHoles – Adds pixels to the input region so that it contains no holes.

RegionOrientation

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the orientation of a region as an angle of value in a proper range.

Syntax

```
void avl::RegionOrientation
(
 const avl::Region& inRegion,
 avl::AngleRange::Type inAngleRange,
 float& outOrientationAngle
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inAngleRange	AngleRange::Type	_0_180	Switches between ranges <0; 90), <0; 180) and <0; 360)
←	outOrientationAngle	float&		

Description

Region orientation can be thought of as the direction in which the region is oriented. Mathematically it is the angle between X-axis and the line passing through the region mass center, that rotation around this line produces the smallest torque.

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Examples

Orientation of the sample region equals to 53.496, which is visualized on the second image by drawing the line of this orientation passing through the region mass center.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionOrientation.

See Also

- PolygonOrientation – Computes the polygon orientation as angle with value in range 0.0 – 180.0.

RegionPerimeterLength

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the length of the input region perimeter.

Syntax

```
void avl::RegionPerimeterLength
(
 const avl::Region& inRegion,
 float& outPerimeterLength
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
⬅	outPerimeterLength	float&		

Description

The operation computes the perimeter length of a region **shape**. Because regions are pixel-precise, the literal computation of the length of the region contour would lead to the overestimation of the diagonal edges. Therefore, the filter employs the following equation to approximate the result:

$$Perimeter(r) \approx a \cdot sides - b \cdot vertices$$

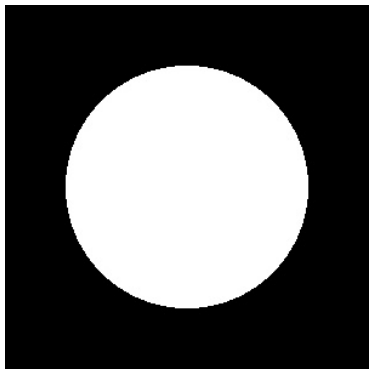
Where

- **sides** denotes the number of pixel sides adjacent to the region background
- **vertices** is the number of turns to right during clockwise walk along the pixel sides of the region boundary
- **a**, **b** are constants defined as follows:

$$a = \frac{\pi(1+\sqrt{2})}{8}$$
$$b = \frac{\pi}{4\sqrt{2}}$$

To compute the actual contour of the region, one can use RegionContours filter.

Examples



RegionPerimeterLength *run on the sample region (circular region of radius 100) computes* ***outPerimeterLength*** *= 627.382, while the actual perimeter of the perfect circle of radius 100 is 628.318 .*

See Also

- RegionContours – Computes an array of closed paths corresponding to the contours of the input region.
- RegionDiameter – Computes the longest segment connecting two pixels contained in region and its length.

RegionPointRunLengths

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Returns the lengths of horizontal sequences of locations that constitute the input region.

Syntax

```
void avl::RegionPointRunLengths
(
 const avl::Region& inRegion,
 atl::Array< int >& outPointRunLengths
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outPointRunLengths	Array< int >&		

RegionProjection

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the profile of the region pixel count in consecutive rows or columns.

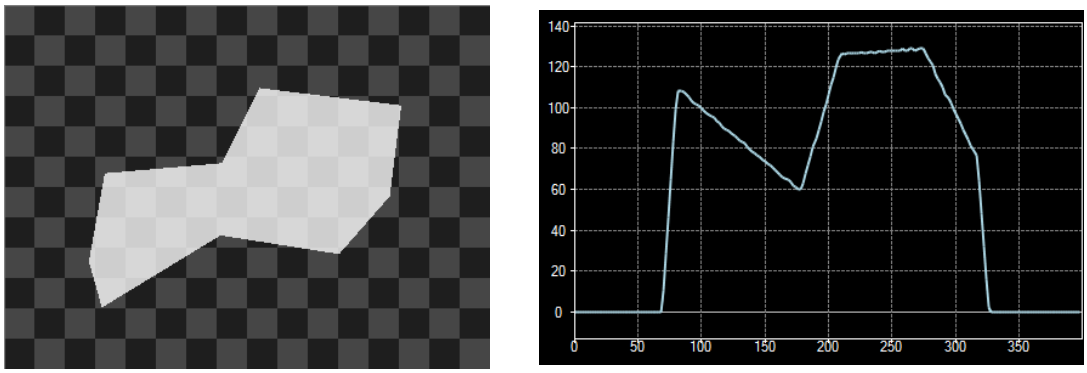
Syntax

```
void avl::RegionProjection
(
 const avl::Region& inRegion,
 const avl::ProjectionDirection::Type inProjectionDirection,
 avl::Profile& outProfile
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inProjectionDirection	const ProjectionDirection::Type		Direction in which the pixel occurrences are counted, 'horizontal' means summation row after row, 'vertical' indicates summation column after column
←	outProfile	Profile&		Profile of pixel count in consecutive rows/columns

Examples



__RegionProjection__ performed on a sample region with __inProjectionDirection__ = Vertical.

RegionRectangularity

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the area of a region divided by the area of its bounding rectangle.

Syntax

```
void avl::RegionRectangularity
(
 const avl::Region& inRegion,
 float& outRectangularity
)
```

Parameters

	Name	Type	Default	Description
➡	inRegion	const Region&		Input region
⬅	outRectangularity	float&		

Hints

- If the input region is not guaranteed to be non-empty, precede this filter with SkipEmptyRegion.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionRectangularity.

RegionsFeatureValues

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes the feature values of the input regions.

Syntax

```
void avl::RegionsFeatureValues
(
 const atl::Array<avl::Region>& inRegions,
 avl::RegionFeature::Type inFeature,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Default	Description
➡	inRegions	const Array<Region>&		Input regions
➡	inFeature	RegionFeature::Type		Region feature value to be computed
⬅	outValues	Array<float>&		

RegionSkewness

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Directional standard deviation of the distance of the region's points to the center.

Syntax

```
void avl::RegionSkewness
(
 const avl::Region& inRegion,
 const float inOrientation,
 const avl::ProjectionDirection::Type inDirection,
 float& outSkewness
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
→	inOrientation	const float		
→	inDirection	const ProjectionDirection::Type	Horizontal	
←	outSkewness	float&		

RegionThickness

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Diameter of the biggest inscribed circle.

Syntax

```
void avl::RegionThickness
(
 const avl::Region& inRegion,
 float& outThickness
)
```

Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outThickness	float&		

126. Region Point Transforms

Table of content:

- RegionComplement

RegionComplement

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region of pixels not contained in the input region.

Syntax

```
void avl::RegionComplement
(
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

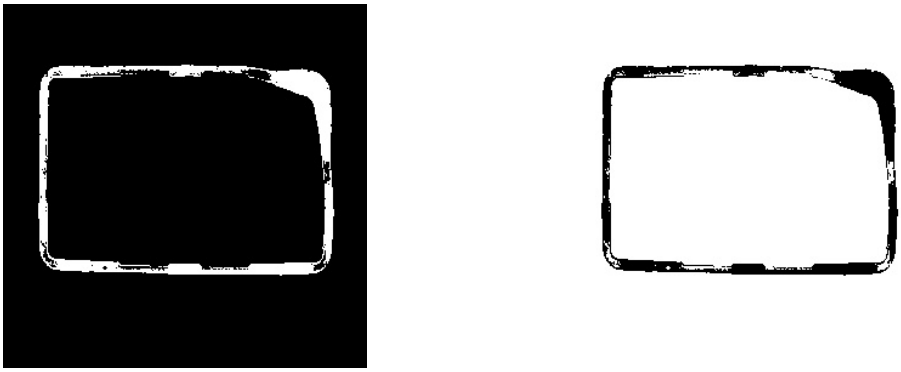
Parameters

	Name	Type	Default	Description
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

The operation computes a region of the same dimensions, containing only pixels that do not belong to the given one.

Examples



RegionComplement *run on a sample region.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in RegionComplement.

127. Region Combinators

Table of content:

- RegionDifference
- RegionIntersection
- RegionIntersection_OfArray
- RegionIntersection_OfLoop
- RegionSymmetricDifference
- RegionSymmetricDifference_OfArray
- RegionSymmetricDifference_OfLoop
- RegionUnion
- RegionUnion_OfArray
- RegionUnion_OfLoop

RegionDifference

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region containing pixels from the first input region but not from the second input region.

Syntax

```
void avl::RegionDifference
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 avl::Region& outRegion
)
```

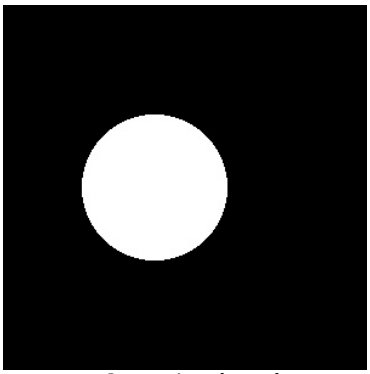
Parameters

	Name	Type	Default	Description
→	inRegion1	const Region&		First input region
→	inRegion2	const Region&		Second input region
←	outRegion	Region&		Output region

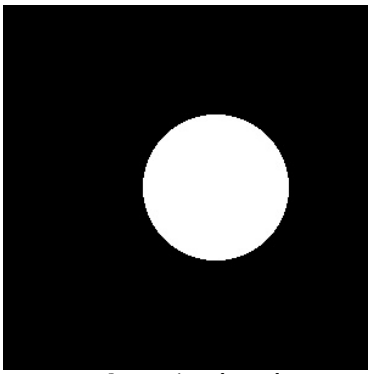
Description

The operation computes the logical difference of two given regions. That is, the resulting region contains pixel locations that belong to the first input region but do **not** belong to the second one. Both dimensions (width and height) of the resulting region are set to the corresponding dimensions of the **first** input region.

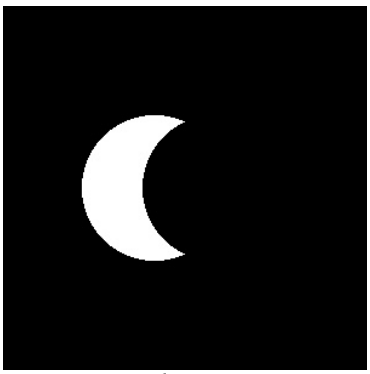
Examples



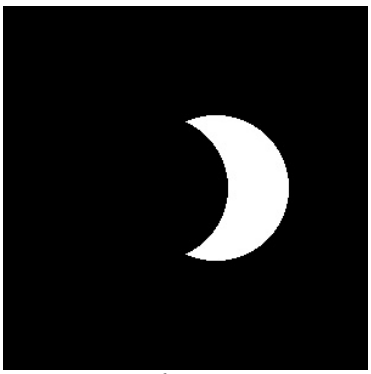
*Sample region **inRegion1***



*Sample region **inRegion2***



RegionDifference(inRegion1, inRegion2)



RegionDifference(inRegion2, inRegion1)

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in RegionDifference.

See Also

- RegionSymmetricDifference – Computes a region containing pixels from first or second input region, but not from both.

RegionIntersection

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common part of two regions.

Syntax

```
void avl::RegionIntersection
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 avl::Region& outRegion
)
```

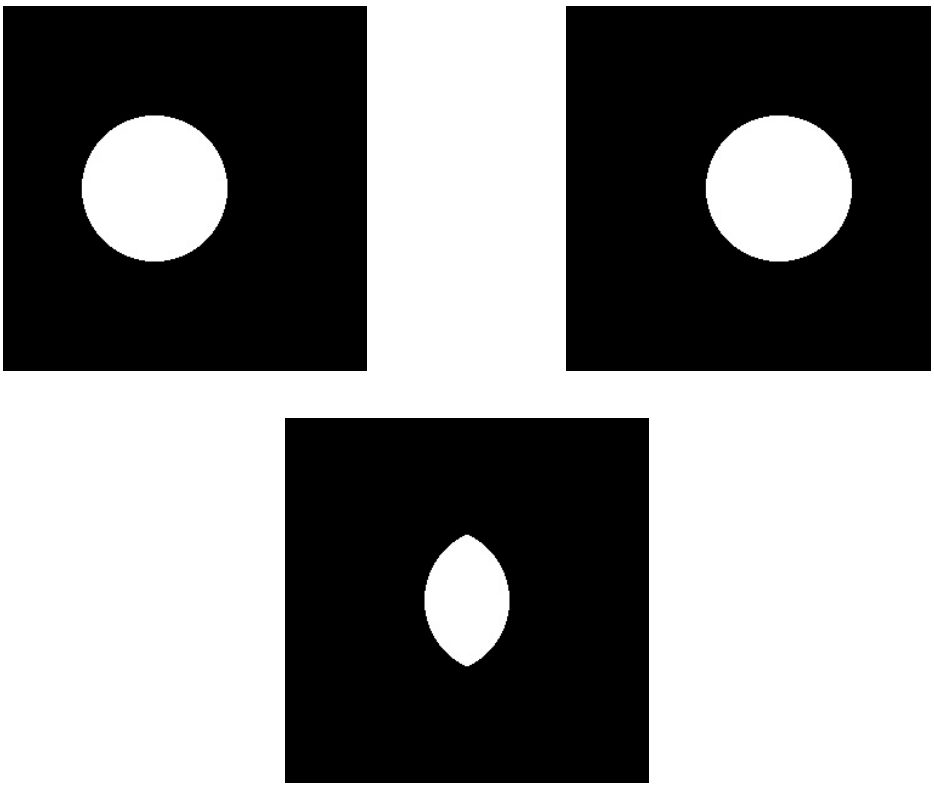
Parameters

	Name	Type	Default	Description
→	inRegion1	const Region&		First input region
→	inRegion2	const Region&		Second input region
←	outRegion	Region&		Output region

Description

The operation computes the logical intersection of two given regions. That is, the resulting region contains pixel locations that belong to both of the given regions. Both dimensions (width and height) of the resulting region are set to the **minimum** of the corresponding dimensions of the input regions.

Examples



***RegionIntersection** run on the sample regions.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in RegionIntersection.

See Also

- RegionUnion – Computes a region containing pixels from both input regions.

RegionIntersection_OfArray

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common part of an array of regions.

Syntax

```
void avl::RegionIntersection_OfArray
(
 atl::Optional<const avl::Region&> inInitialRegion,
 const atl::Array<avl::Region>& inArray,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inInitialRegion	Optional<const Region&>	NIL	
→	inArray	const Array<Region>&		
←	outRegion	Region&		Output region

Description

Array version of RegionIntersection.

Errors

List of possible exceptions:

Error type	Description
DomainError	Input array is empty and inInitialRegion isn't set in RegionIntersection_OfArray.

See Also

- RegionIntersection – Computes the common part of two regions.

RegionIntersection_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the common part of regions appearing in consecutive iterations.

Syntax

```
void avl::RegionIntersection_OfLoop
(
 RegionCombinators_OfLoopState& ioState,
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
	ioState	RegionCombinators_OfLoopState&		Object used to maintain state of the function.
	inRegion	const Region&		Input region
	outRegion	Region&		Output region

Description

Loop version of RegionIntersection.

See Also

- RegionIntersection – Computes the common part of two regions.

RegionSymmetricDifference

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region containing pixels from first or second input region, but not from both.

Syntax

```
void avl::RegionSymmetricDifference
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 avl::Region& outRegion
)
```

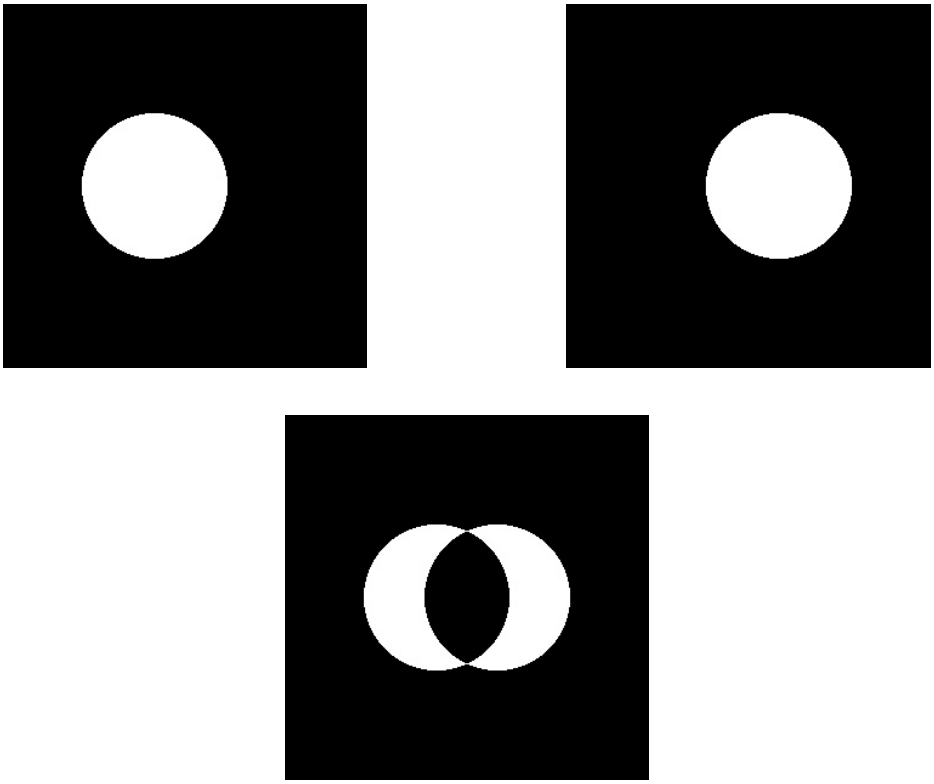
Parameters

	Name	Type	Default	Description
	inRegion1	const Region&		First input region
	inRegion2	const Region&		Second input region
	outRegion	Region&		Output region

Description

The operation computes the logical symmetric difference of two given regions. That is, the resulting region contains pixel locations that belong to one of the given regions, but **not** to both of them. Both dimensions (width and height) of the resulting region are set to the maximum of the corresponding dimensions of the input regions.

Examples



***RegionSymmetricDifference** run on the sample regions.*

See Also

- RegionDifference – Computes a region containing pixels from the first input region but not from the second input region.

Also in **AVL Lite**

RegionSymmetricDifference_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region containing pixels belonging to an odd number of array regions.

Syntax

```
void avl::RegionSymmetricDifference_OfArray
(
 const atl::Array<avl::Region>& inRegionArray,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inRegionArray	const Array<Region>&		
←	outRegion	Region&		Output region

Description

Array version of RegionSymmetricDifference.

See Also

- RegionSymmetricDifference – Computes a region containing pixels from first or second input region, but not from both.

RegionSymmetricDifference_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationPro

Computes a region containing pixels belonging to an odd number of regions appearing in consecutive iterations.

Syntax

```
void avl::RegionSymmetricDifference_OfLoop
(
 RegionCombinators_OfLoopState& ioState,
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RegionCombinators_OfLoopState&		Object used to maintain state of the function.
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

Loop version of RegionSymmetricDifference.

See Also

- RegionSymmetricDifference – Computes a region containing pixels from first or second input region, but not from both.

Also in AVL Lite

RegionUnion

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region containing pixels from both input regions.

Syntax

```
void avl::RegionUnion
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 avl::Region& outRegion
)
```

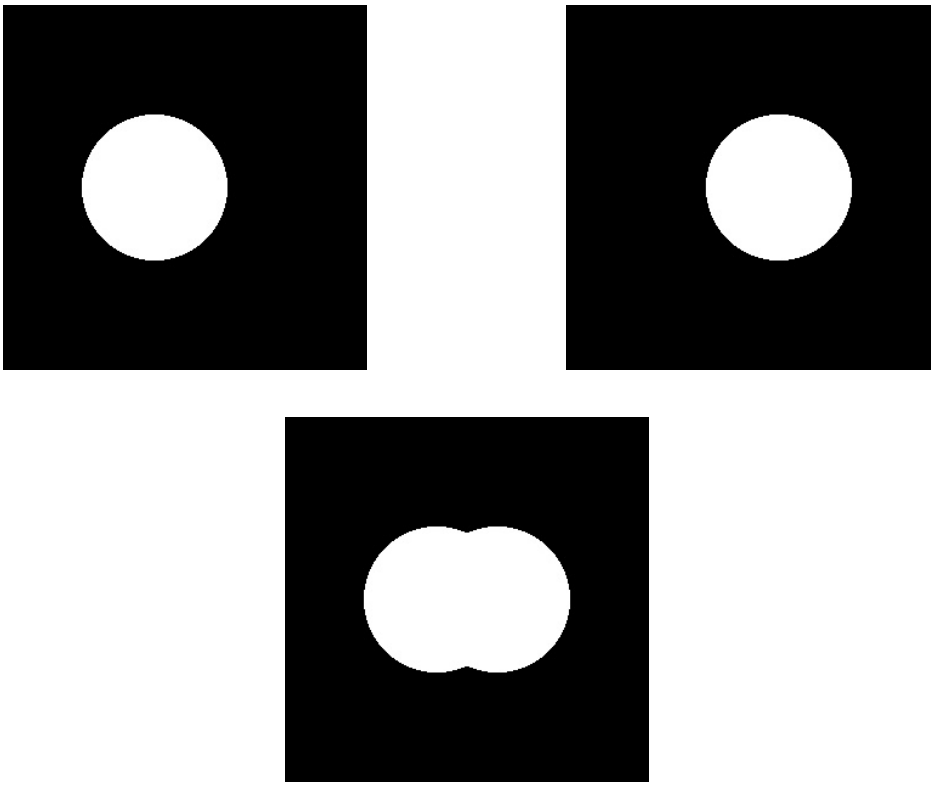
Parameters

	Name	Type	Default	Description
→	inRegion1	const Region&		First input region
→	inRegion2	const Region&		Second input region
←	outRegion	Region&		Output region

Description

The operation computes the logical union of two given regions. That is, the resulting region contains pixel locations that belong to one or both of the given regions. Both dimensions (width and height) of the resulting region are set to the **maximum** of corresponding dimensions of the input regions.

Examples



RegionUnion *run on the sample regions.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Input and output regions are not distinct in RegionUnion.

See Also

- RegionIntersection – Computes the common part of two regions.

Also in AVL Lite

RegionUnion_OfArray

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes a region containing all the pixels that any of the input regions contains.

Syntax

```
void avl::RegionUnion_OfArray
(
 const atl::Array<avl::Region>& inArray,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
→	inArray	const Array<Region>&		Array of regions
←	outRegion	Region&		Union of the input regions

Description

Array version of RegionUnion.

See Also

- RegionUnion – Computes a region containing pixels from both input regions.

Also in AVL Lite

RegionUnion_OfLoop

Header: AVL.h
Namespace: avl
Module: FoundationLite

Computes the union of regions appearing in consecutive iterations.

Syntax

```
void avl::RegionUnion_OfLoop
(
 RegionCombinators_OfLoopState& ioState,
 const avl::Region& inRegion,
 avl::Region& outRegion
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RegionCombinators_OfLoopState&		Object used to maintain state of the function.
→	inRegion	const Region&		Input region
←	outRegion	Region&		Output region

Description

Loop version of RegionUnion.

See Also

- RegionUnion – Computes a region containing pixels from both input regions.

128. Region Metrics

Table of content:

- RegionToRegionDistance

RegionToRegionDistance

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes minimal distance between one of the points of the first region with one of the points of the second region.

Syntax

```
void avl::RegionToRegionDistance
(
 const avl::Region& inRegion1,
 const avl::Region& inRegion2,
 float inResolution,
 float& outDistance,
 atl::Optional<avl::Segment2D&> outConnectingSegment = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRegion1	const Region&			First input region
→	inRegion2	const Region&			Second input region
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
←	outDistance	float&			
←	outConnectingSegment	Optional<Segment2D&>		NIL	

Optional Outputs

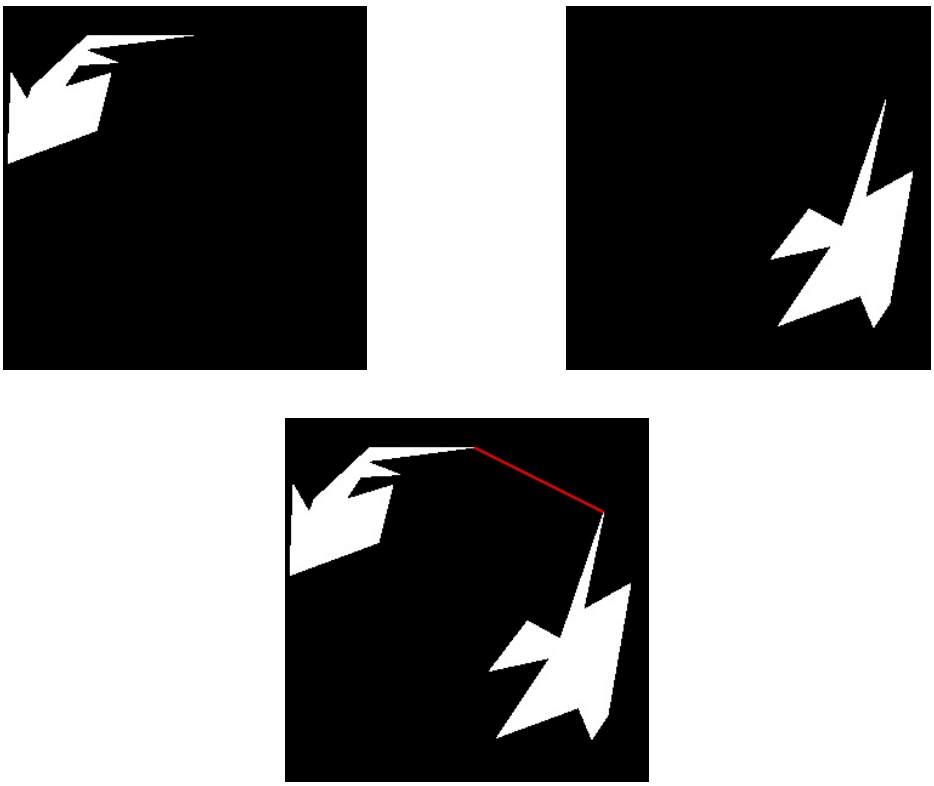
The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outConnectingSegment**.

Read more about Optional Outputs.

Description

Operation computes length of the shortest segment that connects center of one of **inRegion1**'s point which center of one of **inRegion2**'s point.

Examples



RegionToRegionDistance *performed on sample regions produced* ***outDistance*** *= 118,5116. The shortest segment connecting regions is presented on the bottom image*

Remarks

- **inRegion1** and **inRegion2** must not be empty, otherwise an error with appropriate description occurs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty region on input in RegionToRegionDistance.

129. Geometry 3D Normalizations

Table of content:

- RemoveInvalidPoints3D

RemoveInvalidPoints3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Removes invalid 3D points from an array (i.e. points with NaN or INF coordinates).

Syntax

```
void avl::RemoveInvalidPoints3D
(
 const atl::Array<avl::Point3D>& inPoints3D,
 atl::Array<avl::Point3D>& outPoints3D
)
```

Parameters

	Name	Type	Default	Description
	inPoints3D	const Array<Point3D>&		
	outPoints3D	Array<Point3D>&		

130. Surface Features

Table of content:

- ReplaceInvalidSurfacePoints
- SurfaceArea
- SurfaceBoundingBox
- SurfaceBoundingBox_OrNil
- SurfaceFlatness
- SurfaceLocalMaxima
- SurfaceLocalMinima
- SurfaceMassCenter
- SurfaceMassCenter_OrNil
- SurfaceMaximalPoint
- SurfaceMedian
- SurfaceMedian_OrNil
- SurfaceMinimalPoint
- SurfaceMultiplePointsAlongAxis
- SurfaceMultipleProfilesAlongAxis
- SurfaceNormalsImage
- SurfaceProfileAlongPath
- SurfaceSinglePointsAlongAxis
- SurfaceSingleProfileAlongAxis
- SurfaceToPlaneDistanceImage
- SurfaceValidPointsRegion
- SurfaceVolume_Double
- SurfaceVolume_Single

ReplaceInvalidSurfacePoints

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Replaces all invalid points with a given Z value.

Syntax

```
void avl::ReplaceInvalidSurfacePoints
(
 avl::Surface& ioSurface,
 atl::Optional<const avl::Region&> inRoi,
 float inNewZ
)
```

Parameters

	Name	Type	Default	Description
	ioSurface	Surface&		
	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
	inNewZ	float		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in ReplaceInvalidSurfacePoints.

SurfaceArea

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the surface area of given surface.

Syntax

```
void avl::SurfaceArea
(
 const avl::Surface& inSurface,
 float& outArea
)
```

Parameters

	Name	Type	Default	Description
	inSurface	const Surface&		Input surface
	outArea	float&		Area of the input surface

SurfaceBoundingBox

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the bounding box 3D of given surface.

Syntax

```
void avl::SurfaceBoundingBox
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Box3D& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outBoundingBox3D	Box3D&		Bounding box of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid point in given region in SurfaceBoundingBox.
DomainError	Region of interest exceeds an input surface in SurfaceBoundingBox.

SurfaceBoundingBox_OrNil

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the bounding box 3D of given surface; returns NIL if no valid point is present.

Syntax

```
void avl::SurfaceBoundingBox_OrNil
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 atl::Conditional<avl::Box3D>& outBoundingBox3D
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outBoundingBox3D	Conditional<Box3D>&		Bounding box of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceBoundingBox_OrNil.

SurfaceFlatness

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the surface flatness i.e. how thick the surface is according to the input plane.

Syntax

```
void avl::SurfaceFlatness
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Plane3D& inPlane,
 avl::Point3D& outMaximumPoint1,
 avl::Point3D& outMaximumPoint2,
 float& outMaximumDistance1,
 float& outMaximumDistance2,
 float& outFlatness
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inPlane	const Plane3D&		Input plane
←	outMaximumPoint1	Point3D&		Surface point with the largest distance on one side of the plane
←	outMaximumPoint2	Point3D&		Surface point with the largest distance on the other side of the plane
←	outMaximumDistance1	float&		Distance of the first maximum point from the input plane
←	outMaximumDistance2	float&		Distance of the second maximum point from the input plane
←	outFlatness	float&		Difference between two extremal distances of surface points from the input plane

Errors

List of possible exceptions:

Error type	Description
DomainError	No points available to compute surface flatness in SurfaceFlatness.
DomainError	Region of interest exceeds an input surface in SurfaceFlatness.

SurfaceLocalMaxima

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds surface locations characterized by locally maximal heights.

Applications: Detection of characteristic points, usually after some surface transformations.

Syntax

```
void avl::SurfaceLocalMaxima
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 bool inConsiderPlateaus,
 atl::Optional<float> inMinHeight,
 atl::Optional<float> inMaxHeight,
 float inMinDistance,
 atl::Optional<const avl::SurfaceLocalExtremaVerification&> inMaximaVerification,
 atl::Optional<atl::Array<avl::SurfaceExtremum>&> outLocalMaxima,
 atl::Optional<atl::Array<avl::Region>&> outMaximaRegions = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inConsiderPlateaus	bool			Consider multi-pixel maxima (plateaus) or not
→	inMinHeight	Optional<float>		NIL	Minimal height of maximum to be considered
→	inMaxHeight	Optional<float>		NIL	Maximal height of maximum to be considered
→	inMinDistance	float	0.0 – ∞		Minimal distance between two found maxima
→	inMaximaVerification	Optional<const SurfaceLocalExtremaVerification&>		NIL	Maxima verification structure
←	outLocalMaxima	Optional<Array<SurfaceExtremum>&>			Found local maxima
←	outMaximaRegions	Optional<Array<Region>&>		NIL	Regions of local maxima (plateaus and singletons)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLocalMaxima**, **outMaximaRegions**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceLocalMaxima.

SurfaceLocalMinima

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds surface locations characterized by locally minimal heights.

Applications: Detection of characteristic points, usually after some surface transformations.

Syntax

```
void avl::SurfaceLocalMinima
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 bool inConsiderLowlands,
 atl::Optional<float> inMinHeight,
 atl::Optional<float> inMaxHeight,
 float inMinDistance,
 atl::Optional<const avl::SurfaceLocalExtremaVerification&> inMinimaVerification,
 atl::Optional<atl::Array<avl::SurfaceExtremum>&> outLocalMinima,
 atl::Optional<atl::Array<avl::Region>&> outMinimaRegions = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inConsiderLowlands	bool			Consider multi-pixel minima (lowlands) or not
→	inMinHeight	Optional<float>		NIL	Minimal height of minimum to be considered
→	inMaxHeight	Optional<float>		NIL	Maximal height of minimum to be considered
→	inMinDistance	float	0.0 – ∞		Minimal distance between two found minima
→	inMinimaVerification	Optional<const SurfaceLocalExtremaVerification&>		NIL	Minima verification structure
←	outLocalMinima	Optional<Array<SurfaceExtremum>&>			Found local minima
←	outMinimaRegions	Optional<Array<Region>&>		NIL	Regions of local minima (plateaus and singletons)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outLocalMinima**, **outMinimaRegions**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceLocalMinima.

SurfaceMassCenter

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the mass center of surface points.

Syntax

```
void avl::SurfaceMassCenter
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Point3D& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMassCenter	Point3D&		Mass center of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid point in given region in SurfaceMassCenter.
DomainError	Region of interest exceeds an input surface in SurfaceMassCenter.

SurfaceMassCenter_OrNil

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the mass center of surface points; returns NIL if the surface is empty in the given region.

Syntax

```
void avl::SurfaceMassCenter_OrNil
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 atl::Conditional<avl::Point3D>& outMassCenter
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMassCenter	Conditional<Point3D>&		Mass center of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceMassCenter_OrNil.

SurfaceMaximalPoint

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface point with maximal Z coordinate.

Syntax

```
void avl::SurfaceMaximalPoint
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Point3D& outMaximalPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMaximalPoint	Point3D&		Point with maximal Z coordinate

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid point in given region while computing Surface extremal point.
DomainError	Region of interest exceeds an input surface in SurfaceMaximalPoint.

SurfaceMedian

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the median Z coordinate of the surface points.

Syntax

```
void avl::SurfaceMedian
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 float& outMedian
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMedian	float&		Median Z coordinate of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid point in given region in SurfaceMedian.
DomainError	Region of interest exceeds an input surface in SurfaceMedian.

SurfaceMedian_OrNil

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the median Z coordinate of the surface points; returns NIL if the surface is empty in the given region.

Syntax

```
void avl::SurfaceMedian_OrNil
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 atl::Conditional<float>& outMedian
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMedian	Conditional<float>&		Median Z coordinate of the surface points

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceMedian_OrNil.

SurfaceMinimalPoint

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Finds the surface point with minimal Z coordinate.

Syntax

```
void avl::SurfaceMinimalPoint
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Point3D& outMinimalPoint
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outMinimalPoint	Point3D&		Point with minimal Z coordinate

Errors

List of possible exceptions:

Error type	Description
DomainError	No valid point in given region while computing Surface extremal point.
DomainError	Region of interest exceeds an input surface in SurfaceMinimalPoint.

SurfaceMultiplePointsAlongAxis

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns multiple arrays of surface points along X or Y axis.

Syntax

```
void avl::SurfaceMultiplePointsAlongAxis
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Surface&> inSurface2,
 avl::Axis::Type inAxis,
 atl::Optional<double> inCoordinateValueStart,
 atl::Optional<double> inCoordinateValueEnd,
 atl::Optional<double> inCoordinateValueStep,
 int inSmoothRadius,
 atl::Optional<double> inMinOutputCoordinate,
 atl::Optional<double> inMaxOutputCoordinate,
 atl::Optional<int> inMaxInterpolationLength,
 atl::Array<atl::Array<avl::Point3D>>& outPoints,
 atl::Optional<atl::Array<double>&> outCoordinateValues = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inSurface2	Optional<const Surface&>		NIL	Optional second input surface
→	inAxis	Axis::Type			Axis along which the points are extracted
→	inCoordinateValueStart	Optional<double>		NIL	Determines the coordinate the first row of points will be extracted from
→	inCoordinateValueEnd	Optional<double>		NIL	Limits the coordinate the last row of points will be extracted from
→	inCoordinateValueStep	Optional<double>	0.0D – ∞	NIL	Determines the distance between consecutive extracted row of points
→	inSmoothRadius	int	0 – ∞		Increases the number of neighbouring points taken into account extracting a single row of points
→	inMinOutputCoordinate	Optional<double>		NIL	Minimal second coordinate of the output points
→	inMaxOutputCoordinate	Optional<double>		NIL	Maximal second coordinate of the output points
→	inMaxInterpolationLength	Optional<int>	0 – ∞	0	Maximal number of consecutive not existing points to be interpolated
←	outPoints	Array<Array<Point3D>>&			The resulting surface points
←	outCoordinateValues	Optional<Array<double>&>		NIL	The coordinates the output points were extracted from

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCoordinateValues**.

Read more about Optional Outputs.

SurfaceMultipleProfilesAlongAxis

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates the profiles of point Z values along X or Y axis.

Syntax

```
void avl::SurfaceMultipleProfilesAlongAxis
(
 const avl::Surface& inSurface,
 avl::Axis::Type inAxis,
 atl::Optional<double> inCoordinateValueStart,
 atl::Optional<double> inCoordinateValueEnd,
 atl::Optional<double> inCoordinateValueStep,
 int inSmoothRadius,
 atl::Optional<double> inProfileDomainStart,
 atl::Optional<double> inProfileDomainEnd,
 atl::Optional<int> inMaxInterpolationLength,
 float inDefaultValue,
 atl::Array<avl::Profile>& outProfiles,
 atl::Optional<atl::Array<double>&> outCoordinateValues = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inAxis	Axis::Type			Axis along which the profile is extracted
→	inCoordinateValueStart	Optional<double>		NIL	Determines the coordinate the first profile will be extracted from
→	inCoordinateValueEnd	Optional<double>		NIL	Limits the coordinate the last profile will be extracted from
→	inCoordinateValueStep	Optional<double>	0.0D – ∞	NIL	Determines the distance between consecutive extracted profiles
→	inSmoothRadius	int	0 – ∞		Increases the number of neighbouring profiles taken into account extracting a single profile
→	inProfileDomainStart	Optional<double>		NIL	Minimal X coordinate of the output profiles
→	inProfileDomainEnd	Optional<double>		NIL	Maximal X coordinate of the output profiles
→	inMaxInterpolationLength	Optional<int>	0 – ∞	NIL	Maximal number of consecutive not existing profile points to be interpolated
→	inDefaultValue	float			Default value of the not existing and not interpolated surface point
←	outProfiles	Array<Profile>&			The resulting profiles of the surface height
←	outCoordinateValues	Optional<Array<double>&>		NIL	The coordinates the output profiles were extracted from

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCoordinateValues**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Coordinate value range exceeds input surface in SurfaceMultipleProfilesAlongAxis.
DomainError	Incorrect output profile domain in SurfaceMultipleProfilesAlongAxis.
DomainError	Non-positive coordinate value step in SurfaceMultipleProfilesAlongAxis.
DomainError	Unknown axis type in SurfaceMultipleProfilesAlongAxis.

SurfaceNormalsImage

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes a normals image for a surface

Syntax

```
void avl::SurfaceNormalsImage
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const float inScale,
 avl::Image& outNormalsImage,
 atl::Optional<avl::Region&> outComputedRegion = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inScale	const float	0.0 – ∞	1.0f	
←	outNormalsImage	Image&			
←	outComputedRegion	Optional<Region&>		NIL	

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outComputedRegion**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceNormalsImage.

SurfaceProfileAlongPath

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates a series of segments across the input path, measures the average surface height on each of the segments, and creates the final profile from those values.

Applications: This is the first step of all 1D Edge Detection 3D operations. Here available for direct use by the user.

Syntax

```
void avl::SurfaceProfileAlongPath
(
 ScanMapState& ioState,
 const avl::Surface& inSurface,
 const avl::Path& inScanPath,
 atl::Optional<const avl::CoordinateSystem2D&> inScanPathAlignment,
 atl::Optional<float> inSamplingStep,
 int inScanWidth,
 avl::InterpolationMethod::Type inSurfaceInterpolation,
 atl::Optional<int> inMaxInterpolationLength,
 float inSmoothingStdDev,
 avl::Profile& outProfile,
 avl::Path& outPath,
 atl::Optional<avl::Path&> outAlignedScanPath = atl::NIL,
 atl::Array<avl::Path>& diagSamplingPoints
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ScanMapState&			Object used to maintain state of the function.
	inSurface	const Surface&			Input surface
	inScanPath	const Path&			Path along which the profile is extracted
	inScanPathAlignment	Optional<const CoordinateSystem2D&>		NIL	Adjusts the scan path to the position of the inspected object
	inSamplingStep	Optional<float>	0.0 – ∞	NIL	Distance between consecutive sampling points on the scan path; if Nil, the bigger of surface X and Y scales is chosen
	inScanWidth	int	1 – ∞	5	Width of the scan field
	inSurfaceInterpolation	InterpolationMethod::Type		Bilinear	Interpolation method used for extraction of surface points
	inMaxInterpolationLength	Optional<int>		NIL	Maximal number of consecutive not existing profile points
	inSmoothingStdDev	float	0.0 – ∞	0.6f	Standard deviation of the gaussian smoothing applied to the extracted profile
	outProfile	Profile&			The resulting profile of the surface height
	outPath	Path&			The path consisting of the points from which the resulting profile is extracted
	outAlignedScanPath	Optional<Path&>		NIL	Path along which the scan is performed
	diagSamplingPoints	Array<Path>&			Array of paths each one containing the sampling points that contributed to a single value of the extracted profile; in the image coordinate system

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outAlignedScanPath**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Non-positive sampling step on input in SurfaceProfileAlongPath.
DomainError	Non-positive scale on input in SurfaceProfileAlongPath.

SurfaceSinglePointsAlongAxis

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Returns single array of surface points along X or Y axis.

Syntax

```
void avl::SurfaceSinglePointsAlongAxis
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Surface&> inSurface2,
 avl::Axis::Type inAxis,
 double inCoordinateValue,
 int inSmoothRadius,
 atl::Optional<double> inMinOutputCoordinate,
 atl::Optional<double> inMaxOutputCoordinate,
 atl::Optional<int> inMaxInterpolationLength,
 atl::Array<avl::Point3D>& outPoints,
 atl::Optional<double&> outCoordinateValue = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inSurface2	Optional<const Surface&>		NIL	Optional second input surface
→	inAxis	Axis::Type			Axis along which the points are extracted
→	inCoordinateValue	double			Determines the coordinate the points will be extracted from
→	inSmoothRadius	int	0 – ∞		Increases the number of neighbouring points taken into account
→	inMinOutputCoordinate	Optional<double>		NIL	Minimal second coordinate of the output points
→	inMaxOutputCoordinate	Optional<double>		NIL	Maximal second coordinate of the output points
→	inMaxInterpolationLength	Optional<int>	0 – ∞	0	Maximal number of consecutive not existing points to be interpolated
←	outPoints	Array<Point3D>&			The resulting surface points
←	outCoordinateValue	Optional<double&>		NIL	The coordinate the output points were extracted from

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCoordinateValue**.

Read more about Optional Outputs.

SurfaceSingleProfileAlongAxis

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Creates the profile of point Z values along X or Y axis.

Syntax

```
void avl::SurfaceSingleProfileAlongAxis
(
 const avl::Surface& inSurface,
 avl::Axis::Type inAxis,
 double inCoordinateValue,
 int inSmoothRadius,
 atl::Optional<double> inProfileDomainStart,
 atl::Optional<double> inProfileDomainEnd,
 atl::Optional<int> inMaxInterpolationLength,
 float inDefaultValue,
 avl::Profile& outProfile,
 atl::Optional<double&> outCoordinateValue = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inAxis	Axis::Type			Axis along which the profile is extracted
→	inCoordinateValue	double			Determines the coordinate the profile will be extracted from
→	inSmoothRadius	int	0 – ∞		Increases the number of neighbouring profiles taken into account extracting a profile
→	inProfileDomainStart	Optional<double>		NIL	Minimal X coordinate of the output profile
→	inProfileDomainEnd	Optional<double>		NIL	Maximal X coordinate of the output profile
→	inMaxInterpolationLength	Optional<int>	0 – ∞	NIL	Maximal number of consecutive not existing profile points to be interpolated
→	inDefaultValue	float			Default value of the not existing and not interpolated surface point
←	outProfile	Profile&			The resulting profile of the surface height
←	outCoordinateValue	Optional<double&>		NIL	The coordinate the output profile was extracted from

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outCoordinateValue**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect output profile domain in SurfaceSingleProfileAlongAxis.
DomainError	Input coordinate value exceeds surface in SurfaceSingleProfileAlongAxis.
DomainError	Unknown axis type in SurfaceSingleProfileAlongAxis.

SurfaceToPlaneDistanceImage

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the image of the distances of the input surface points from a given plane.

Syntax

```
void avl::SurfaceToPlaneDistanceImage
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const avl::Plane3D& inPlane,
 float inResolution,
 bool inSignedDistance,
 avl::Image& outDistanceImage
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			Input surface
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inPlane	const Plane3D&			Input plane
→	inResolution	float	0.0 – ∞	1.0f	Number of real-world units per one pixel
→	inSignedDistance	bool		False	Flag indicating whether to compute signed distance to the plane
←	outDistanceImage	Image&			

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite plane on input in SurfaceToPlaneDistanceImage.
DomainError	Region of interest exceeds an input surface in SurfaceToPlaneDistanceImage.

SurfaceValidPointsRegion

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes region of locations where points are valid in a surface and where they are invalid.

Syntax

```
void avl::SurfaceValidPointsRegion
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::Region& outValidPointsRegion,
 avl::Region& outInvalidPointsRegion
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inRoi	Optional<const Region&>	NIL	Region of interest
←	outValidPointsRegion	Region&		Region of locations where points are valid
←	outInvalidPointsRegion	Region&		Region of locations where points are invalid

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceValidPointsRegion.

SurfaceVolume_Double

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the volume of a surface with respect to another surface.

Syntax

```
void avl::SurfaceVolume_Double
(
 const avl::Surface& inTopSurface,
 const avl::Surface& inBottomSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::VolumeCalculationMethod::Type inVolumeCalculationMethod,
 double& outVolume
)
```

Parameters

	Name	Type	Default	Description
→	inTopSurface	const Surface&		The top surface
→	inBottomSurface	const Surface&		The bottom surface
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inVolumeCalculationMethod	VolumeCalculationMethod::Type		Determines how the parts of a volume are added up
←	outVolume	double&		Volume of the input surface

Errors

List of possible exceptions:

Error type	Description
DomainError	Different surface dimensions between inTopSurface and inBottomSurface in SurfaceVolume_Double.
DomainError	Different surface scales or offsets between inTopSurface and inBottomSurface in SurfaceVolume_Double.
DomainError	Different surface types between inTopSurface and inBottomSurface in SurfaceVolume_Double.
DomainError	Region of interest exceeds an input surface in SurfaceVolume_Double.
DomainError	Unsupported inVolumeCalculationMethod in SurfaceVolume_Double.

SurfaceVolume_Single

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Computes the volume of a surface with respect to a plane.

Syntax

```
void avl::SurfaceVolume_Single
(
 const avl::Surface& inSurface,
 const double inZ,
 atl::Optional<const avl::Region&> inRoi,
 avl::VolumeCalculationMethod::Type inVolumeCalculationMethod,
 double& outVolume,
 atl::Optional<avl::Plane3D&> outPlane = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		Input surface
→	inZ	const double		The volume is calculated with respect to the plane Z = inZ
→	inRoi	Optional<const Region&>	NIL	Range of pixels to be processed
→	inVolumeCalculationMethod	VolumeCalculationMethod::Type		Determines how the parts of a volume are added up
←	outVolume	double&		Volume of the input surface
←	outPlane	Optional<Plane3D&>	NIL	The plane defined as Z = inZ

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outPlane**.

Read more about Optional Outputs.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SurfaceVolume_Single.
DomainError	Unsupported inVolumeCalculationMethod in SurfaceVolume_Single.

131. Surface Interpolations

Table of content:

- ResampleSurface
- ResampleSurface_AnyScales
- SmoothSurface_Gauss
- SmoothSurface_Mean

ResampleSurface

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Equalizes the scales format of the input surface.

Syntax

```
void avl::ResampleSurface
(
 const avl::Surface& inSurface,
 avl::ResampleSurfaceMode::Type inResampleSurfaceMode,
 atl::Optional<double> inXOffset,
 atl::Optional<double> inYOffset,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
→	inSurface	const Surface&		
→	inResampleSurfaceMode	ResampleSurfaceMode::Type		
→	inXOffset	Optional<double>	NIL	Offset for the X axis of the output surface
→	inYOffset	Optional<double>	NIL	Offset for the Y axis of the output surface
←	outSurface	Surface&		

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Incorrect resample mode in ResampleSurface.

ResampleSurface_AnyScales

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Changes the coordinates format of the input surface.

Syntax

```
void avl::ResampleSurface_AnyScales
(
 const avl::Surface& inSurface,
 atl::Optional<double> inXOffset,
 atl::Optional<double> inXScale,
 atl::Optional<double> inYOffset,
 atl::Optional<double> inYScale,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inXOffset	Optional<double>		NIL	Offset for the X axis of the output surface
→	inXScale	Optional<double>	0.000001D – ∞	NIL	Scale for the X axis of the output surface
→	inYOffset	Optional<double>		NIL	Offset for the Y axis of the output surface
→	inYScale	Optional<double>	0.000001D – ∞	NIL	Scale for the Y axis of the output surface
←	outSurface	Surface&			

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Non-positive scale on input in ResampleSurface_AnyScales.

SmoothSurface_Gauss

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Smooths a surface using a gaussian kernel.

Applications: Removal of gaussian noise from surfaces.

Syntax

```
void avl::SmoothSurface_Gauss
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 float inStdDevX,
 atl::Optional<float> inStdDevY,
 const float inKernelRelativeSize,
 avl::Surface& outSurface,
 int& diagKernelRadiusX,
 int& diagKernelRadiusY
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSurface	const Surface&			
➡	inRoi	Optional<const Region&>		NIL	Range of output points to be computed
➡	inStdDevX	float	0.0 – ∞	1.0f	Horizontal smoothing standard deviation
➡	inStdDevY	Optional<float>	0.0 – ∞	NIL	Vertical smoothing standard deviation
➡	inKernelRelativeSize	const float	0.0 – 3.0	2.0f	A multiple of the standard deviation determining the size of the kernel
⬅	outSurface	Surface&			
🔍	diagKernelRadiusX	int&			Horizontal radius of Gaussian kernel being used
🔍	diagKernelRadiusY	int&			Vertical radius of Gaussian kernel being used

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds a surface in SmoothSurface_Gauss.

SmoothSurface_Mean

Header: AVL.h
Namespace: avl
Module: Vision3DStandard

Smooths a surface by averaging heights within a rectangular kernel.

Applications: Usually used for computing features related to local surface "windows". Can be also used for noise removal, but Gauss is superior here.

Syntax

```
void avl::SmoothSurface_Mean
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 avl::KernelShape::Type inKernel,
 int inRadiusX,
 atl::Optional<int> inRadiusY,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of points to be computed
→	inKernel	KernelShape::Type			Kernel shape
→	inRadiusX	int	0 – ∞	1	Nearly half of the kernel's width (2*R+1)
→	inRadiusY	Optional<int>	0 – ∞	NIL	Nearly half of the kernel's height (2*R+1), or same as inRadiusX
←	outSurface	Surface&			

Hardware Acceleration

This operation supports automatic parallelization for multicore and multiprocessor systems.

Errors

List of possible exceptions:

Error type	Description
DomainError	Region of interest exceeds an input surface in SmoothSurface_Mean.

132. Segmentation 3D

Table of content:

- SegmentPoint3DGrid_PlanarCells
- SegmentPoint3DGrid_Planes
- SegmentSurface_PlanarCells
- SegmentSurface_Planes

SegmentPoint3DGrid_PlanarCells

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes a list of planar cells of a point cloud

Syntax

```
void avl::SegmentPoint3DGrid_PlanarCells
(
 const avl::Point3DGrid& inPointCloud,
 const float inCellSize,
 const double inFlatnessNoiseLevel,
 atl::Array<atl::Array<avl::Point3D>>& outPlanarCells,
 atl::Array<avl::Segment3D>& diagPlanarCellNormals,
 atl::Array<avl::Box3D>& diagPlanarCellBoxes
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointCloud	const Point3DGrid&			
→	inCellSize	const float	2.0 – ∞	16.0f	Size of a single cell in the real coordinate system
→	inFlatnessNoiseLevel	const double	0.0D – 1.0D	0.04D	
←	outPlanarCells	Array<Array<Point3D>>&			
🔍	diagPlanarCellNormals	Array<Segment3D>&			Segments representing the normals of computed cells
🔍	diagPlanarCellBoxes	Array<Box3D>&			Bounding boxes of planar cells

SegmentPoint3DGrid_Planes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments a point cloud into planes.

Syntax

```
void avl::SegmentPoint3DGrid_Planes
(
 const avl::Point3DGrid& inPointCloud,
 const float inCellSize,
 const double inFlatnessNoiseLevel,
 int inMaxIterations,
 const float inMaxAngleDeviation,
 const float inMaxDistanceDeviation,
 atl::Array<atl::Array<avl::Point3D>>& outPlanePoints,
 atl::Array<avl::Plane3D>& outPlanes,
 atl::Array<atl::Array<avl::Point3D>>& diagPlanarCells
)
```

Parameters

	Name	Type	Range	Default	Description
→	inPointCloud	const Point3DGrid&			
→	inCellSize	const float	2.0 – ∞	16.0f	Size of a single cell in the real coordinate system
→	inFlatnessNoiseLevel	const double	0.0D – 1.0D	0.04D	
→	inMaxIterations	int	1 – ∞	1000	
→	inMaxAngleDeviation	const float	0.0 – 90.0	15.0f	
→	inMaxDistanceDeviation	const float	0.0 – ∞	0.1f	
←	outPlanePoints	Array<Array<Point3D>>&			
←	outPlanes	Array<Plane3D>&			
🔍	diagPlanarCells	Array<Array<Point3D>>&			Computed planar cells

SegmentSurface_PlanarCells

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Computes a list of planar cells of a surface

Syntax

```
void avl::SegmentSurface_PlanarCells
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const int inCellWidth,
 atl::Optional<int> inCellHeight,
 const double inFlatnessNoiseLevel,
 const float inMinCellCoverage,
 atl::Array<avl::Region>& outPlanarCells,
 atl::Array<avl::Segment3D>& diagPlanarCellNormals,
 atl::Array<avl::Region>& diagCellRegions
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inCellWidth	const int	2 – ∞	16	Width of a single cell in the girds coordinate system
→	inCellHeight	Optional<int>	2 – ∞	NIL	Height of a single cell in the girds coordinate system
→	inFlatnessNoiseLevel	const double	0.0D – 1.0D	0.04D	
→	inMinCellCoverage	const float	0.0 – 1.0	0.3f	Minimum percentage of valid points that a planar cell has to have
←	outPlanarCells	Array<Region>&			
🔍	diagPlanarCellNormals	Array<Segment3D>&			Segments representing the normals of computed cells,
🔍	diagCellRegions	Array<Region>&			Regions of all both planar and non-planar cells

SegmentSurface_Planes

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Segments a surface into planes.

Syntax

```
void avl::SegmentSurface_Planes
(
 const avl::Surface& inSurface,
 atl::Optional<const avl::Region&> inRoi,
 const int inCellWidth,
 atl::Optional<int> inCellHeight,
 const double inFlatnessNoiseLevel,
 int inMaxIterations,
 const double inMaxAngleDeviation,
 const double inMaxDistanceDeviation,
 const float inMinCellCoverage,
 const int inMinPlaneArea,
 atl::Array<avl::Region>& outPlaneRegions,
 atl::Array<avl::Plane3D>& outPlanes,
 atl::Array<avl::Region>& diagPlanarCells
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSurface	const Surface&			
→	inRoi	Optional<const Region&>		NIL	Range of pixels to be processed
→	inCellWidth	const int	2 – ∞	16	Width of a single cell in the girds coordinate system
→	inCellHeight	Optional<int>	2 – ∞	NIL	Height of a single cell in the girds coordinate system
→	inFlatnessNoiseLevel	const double	0.0D – 1.0D	0.04D	
→	inMaxIterations	int	1 – ∞	1000	
→	inMaxAngleDeviation	const double	0.0D – 90.0D	15.0D	
→	inMaxDistanceDeviation	const double	0.0D – ∞	0.1D	
→	inMinCellCoverage	const float	0.0 – 1.0	0.3f	Minimum percentage of valid points that a planar cell has to have
→	inMinPlaneArea	const int	1 – + ∞	1	Minimum number of pixels for a single plane
←	outPlaneRegions	Array<Region>&			
←	outPlanes	Array<Plane3D>&			
🔍	diagPlanarCells	Array<Region>&			Computed planar cells

133. Histogram Local Transforms

Table of content:

- SmoothHistogram_Gauss
- SmoothHistogram_Mean

SmoothHistogram_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Smooths a histogram by averaging points within a kernel using gaussian-weighted average.

Syntax

```
void avl::SmoothHistogram_Gauss
(
 const avl::Histogram& inHistogram,
 atl::Optional<const avl::Range&> inRange,
 const float inStdDev,
 const float inKernelRelativeSize,
 const bool inCyclic,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHistogram	const Histogram&			Input histogram
→	inRange	Optional<const Range&>		NIL	
→	inStdDev	const float	0.0 – ∞	0.6f	Smoothing standard deviation
→	inKernelRelativeSize	const float	0.0 – ∞	3.0f	
→	inCyclic	const bool		False	
←	outHistogram	Histogram&			Output histogram

SmoothHistogram_Mean

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Smooths a histogram by averaging points within a kernel.

Syntax

```
void avl::SmoothHistogram_Mean
(
 const avl::Histogram& inHistogram,
 atl::Optional<const avl::Range&> inRange,
 const int inKernelRadius,
 const bool inCyclic,
 avl::Histogram& outHistogram
)
```

Parameters

	Name	Type	Range	Default	Description
→	inHistogram	const Histogram&			Input histogram
→	inRange	Optional<const Range&>		NIL	
→	inKernelRadius	const int	0 – ∞	3	Defines the width of the kernel as 2*R+1
→	inCyclic	const bool		False	
←	outHistogram	Histogram&			Output histogram

134. Path Local Transforms

Table of content:

- SmoothPath_Gauss
- SmoothPath_Mean

SmoothPath_Gauss

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths a path by averaging its characteristic points within a kernel using gaussian-weighted average.

Syntax

```
void avl::SmoothPath_Gauss
(
 const avl::Path& inPath,
 const float inStdDev,
 const float inKernelRelativeSize,
 avl::Path& outPath
)
```

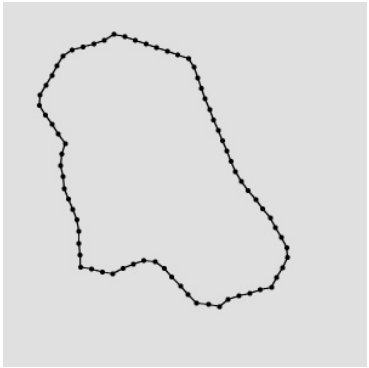
Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inStdDev	const float	0.0 – ∞	0.6f	Smoothing standard deviation
→	inKernelRelativeSize	const float	0.0 – ∞	3.0f	A multiple of the standard deviation determining the size of the kernel
←	outPath	Path&			Output path

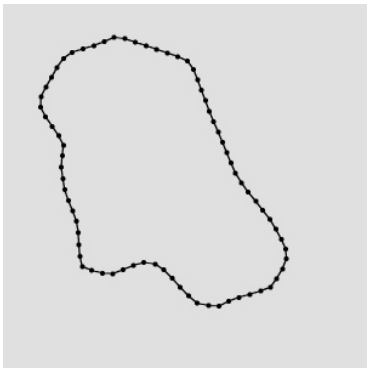
Description

The operation replaces each characteristic point of the path with the local gaussian average, thus smoothing its shape. The local average is computed as a gaussian mean of the consecutive **inStdDev*inKernelRelativeSize** characteristic points.

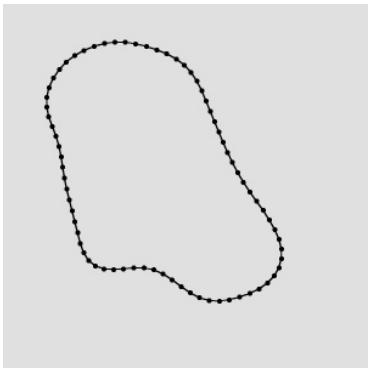
Examples



A sample path



SmoothPath_Gauss *run on the sample path with* ***inStdDev*** *= 0.6 and* ***inKernelRelativeSize*** *= 3.*



SmoothPath_Gauss *run on the sample path with* ***inStdDev*** *= 2 and* ***inKernelRelativeSize*** *= 3.*

See Also

- SmoothPath_Mean – Smooths a path by averaging its characteristic points within a kernel.

SmoothPath_Mean

Header: AVL.h
Namespace: avl
Module: FoundationPro

Smooths a path by averaging its characteristic points within a kernel.

Syntax

```
void avl::SmoothPath_Mean
(
 const avl::Path& inPath,
 int inKernelRadius,
 avl::Path& outPath
)
```

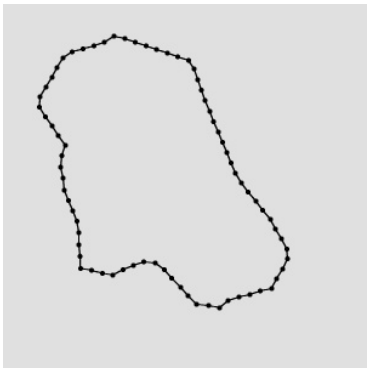
Parameters

	Name	Type	Range	Default	Description
→	inPath	const Path&			Input path
→	inKernelRadius	int	0 – ∞	3	
←	outPath	Path&			Output path

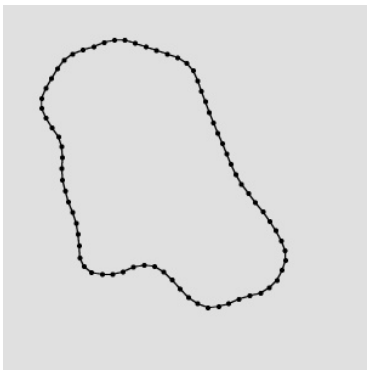
Description

The operation replaces each characteristic point of the path with the local average, thus smoothing its shape. The local average is computed as a simple arithmetic mean of the consecutive 2***inKernelRadius** + 1 characteristic points.

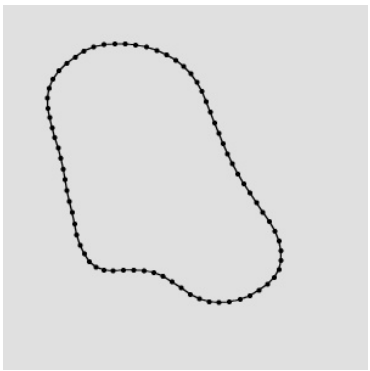
Examples



A sample path



***SmoothPath_Mean** run on the sample path with **inKernelRadius** = 1.*



***SmoothPath_Mean** run on the sample path with **inKernelRadius** = 3.*

Errors

List of possible exceptions:

Error type	Description
DomainError	Kernel size exceeds the number of points in a closed path in SmoothPath_Mean.

See Also

- SmoothPath_Gauss - Smooths a path by averaging its characteristic points within a kernel using gaussian-weighted average.

135. Support Vector Machines

Table of content:

- SVM_ClassifyMultiple
- SVM_ClassifySingle
- SVM_Init
- SVM_Train

SVM_ClassifyMultiple

Header: AVL.h
Namespace: avl
Module: FoundationPro

Classifies input points based on trained model.

Syntax

```
void avl::SVM_ClassifyMultiple
(
 const avl::SvmModel& inSvmModel,
 const atl::Array<atl::Array<float> >& inVectorArray,
 atl::Array< int >& outPredictions,
 atl::Optional<atl::Array< int >& > outModelClasses = atl::NIL,
 atl::Optional<atl::Array<atl::Array<float>>& > outClassProbabilities = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSvmModel	const SvmModel&		Input trained model
→	inVectorArray	const Array<Array<float> >&		Data vector array of unknown classes
←	outPredictions	Array< int >&		Predicted classes
←	outModelClasses	Optional<Array< int >& >	NIL	All known model classes in order
←	outClassProbabilities	Optional<Array<Array<float>>& >	NIL	For each data vector the probability of belonging to each class

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outModelClasses**, **outClassProbabilities**.

Read more about Optional Outputs.

Description

The operation predicts classes for the given data points. It takes an array of data vectors (**inVectorArray**) as an argument. Each vector has to be of the same size as vectors used for training the model. The operation outputs predicted class (**outPredictions**) for each data vector.
outModelClasses are all class labels encountered during training.
outClassProbabilities provides, for each vector, estimated probability of this vector belonging to each class. Precisely, in each array the value under index **i** denotes probability of given vector belonging to the class **outModelClasses[i]**.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty vector array in SVM_ClassifyMultiple.
DomainError	Incorrect vector size in SVM_Classify
DomainError	Incorrect, uninitialized or not trained SvmModel in SVM_ClassifyMultiple.

See Also

- SVM_ClassifySingle – Classifies input features based on a trained model.

SVM_ClassifySingle

Header: AVL.h
Namespace: avl
Module: FoundationPro

Classifies input features based on a trained model.

Syntax

```
void avl::SVM_ClassifySingle
(
 const avl::SvmModel& inSvmModel,
 const atl::Array<float>& inVector,
 int& outPrediction,
 atl::Optional<atl::Array< int >& > outModelClasses = atl::NIL,
 atl::Optional<atl::Array<float>& > outClassProbabilities = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inSvmModel	const SvmModel&		Input trained model
→	inVector	const Array<float>&		Data vector of unknown class
←	outPrediction	int&		Predicted classes
←	outModelClasses	Optional<Array< int >& >	NIL	All known model classes in order
←	outClassProbabilities	Optional<Array<float>& >	NIL	For each data vector the probability of belonging to each class

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outModelClasses**, **outClassProbabilities**.

Read more about Optional Outputs.

Description

The operation predicts classes for the given data points. It takes a data vector (**inVector**) as an argument. The vector has to be of the same size as vectors used for training the model. The operation outputs predicted class (**outPrediction**) for the data vector.
outModelClasses are all class labels encountered during training.
outClassProbabilities provides, for the input vector, estimated probability belonging to each class. Precisely, the value under index **i** denotes probability of given vector belonging to the class **outModelClasses[i]**.

SVM_Init

Header: AVL.h
Namespace: avl
Module: FoundationPro

Initializes an SVM model.

Syntax

```
void avl::SVM_Init
(
 atl::Optional<float> inKernelGamma,
 float inKernelGammaScale,
 float inRegularizationConstant,
 atl::Optional<float> inNu,
 float inStoppingEpsilon,
 bool inUseShrinkingHeuristics,
 avl::SvmModel& outSvmModel
)
```

Parameters

	Name	Type	Range	Default	Description
→	inKernelGamma	Optional<float>	0.0001 – ∞	0.0001f	Gamma parameter for Rbf kernel
→	inKernelGammaScale	float	0.0001 – ∞	1.0f	Gamma parameter scale
→	inRegularizationConstant	float	0.0001 – ∞	1.0f	Preventing overfitting
→	inNu	Optional<float>	0.0001 – 1.0	NIL	Tradeoff between training accuracy and number of SV
→	inStoppingEpsilon	float	0.0001 – ∞	0.001f	Epsilon for stopping criterium
→	inUseShrinkingHeuristics	bool		True	May speed up computations
←	outSvmModel	SvmModel&			Output model

Description

The operation initializes a model for an SVM classifier that will be used by SVM_Train and SVM_ClassifySingle.

Support Vector Machines (SVM or C-SVC) is a classifier based on the support vector idea. Those vectors define hypersurfaces that separate data points from two different classes. The shape of those hypersurfaces is defined by the scalar product dependent on the kernel type. In the simplest case of linear kernel, they define hyperplanes.

Notice that SVM uses one-versus-all evaluation, because it is a binary classifier.

Nu-SVC is a variant of C-SVC making use of Nu parameter. It provides a tradeoff between the number of support vectors and the number of training errors. In fact, it defines a lower bound on the former and an upper bound on the latter.

There are two types of kernels:

- **Linear** is a simple kernel for easier tasks. It is also recommended when the training time is critical.
  The corresponding scalar product is $L(u,v) = u^T v$. This kernel is used when **inKernelGamma** is equal to Auto.
- **Rbf** (radial basis kernel) is the most common and the recommended kernel. Its function is $Rbf_\gamma(u,v) = \exp(-\gamma \|u-v\|^2)$.

SVM_Init parameters are:

- **inKernelGamma** is the γ (gamma) parameter for Rbf kernel. When it is set to Auto, then **Linear** kernel is used.
- **inKernelGammaScale** is used to provide more precise setting the value of **inKernelGamma**.
  As the result kernel gamma value is set to $\gamma = \frac{inKernelGamma}{inKernelGammaScale}$
- **inRegularizationConstant** is the C constant of C-SVC and Nu-SVC. With greater C, the model is less likely to overfit training data.
- **inStoppingEpsilon** defines precision of the training. The smaller this parameter is, the more accurate the training is, but also the longer it takes.
- **inNu** is the Nu parameter of Nu-SVC described above. If it is Auto, then simple C-SVC classifier is used.
- If **inUseShrinkingHeuristics** is set, the algorithm will use the heuristics that shrinks the search region to speed up computation with little or none loss of accuracy.

Getting started:

At the beginning a good choice for SVM type is C-SVC (i.e. to leave **inNu** equal NIL) and the recommended kernel type is **Rbf**. The parameter **inStoppingEpsilon** may be left default (equal 0.001) and it is recommended to set **inUseShrinkingHeuristics** to true. There are two parameters to choose: **inKernelGamma** and **inRegularizationConstant**. The first one is responsible for "tightness" of the class regions and the second one for ignoring detached data points.

The best way to choose those parameters is to perform a *grid search*, i.e. to try different pairs of values, for example pairs of powers of 2. The grid search may be performed on a relatively small subset of training data to reduce training time. Moreover, it is recommended to use *cross-validation*, which means evaluating parameters not on the training data, but on a different data set, to prevent overfitting. One has to remember to choose those subsets at random.

Another thing worth trying is normalizing data before passing it to training and classification procedures. However, data has to be rescaled with the same value for both training and classification data! Normalizing data might improve performance and is useful for optimal parameter choice. If the data vectors are rescaled N times, then gamma in RBF kernel has to be rescaled by term N^{-2} to ensure similar performance.

Remarks

It is recommended there are at least two training samples for each data class in the training set.

See Also

- SVM_ClassifySingle – Classifies input features based on a trained model.
- SVM_Train – Trains an SVM model.

SVM_Train

Header: AVL.h
Namespace: avl
Module: FoundationPro

Trains an SVM model.

Syntax

```
void avl::SVM_Train
(
 const avl::SvmModel& inSvmModel,
 const atl::Array<atl::Array<float> >& inVectorArray,
 const atl::Array< int >& inAnswerArray,
 avl::SvmModel& outSvmModel,
 float& outTrainingAccuracy
)
```

Parameters

	Name	Type	Default	Description
→	inSvmModel	const SvmModel&		Initialized SVM model
→	inVectorArray	const Array<Array<float> >&		Training data vector array
→	inAnswerArray	const Array< int >&		Correct classes for data vectors
←	outSvmModel	SvmModel&		Trained model
←	outTrainingAccuracy	float&		Accuracy of prediction on training set

Description

The operation trains an SVM classifier initialized beforehand by SVM_Init function. It takes two arrays as arguments:

- **inVectorArray**, an array of data points with known classes
- **inAnswerArray**, an array of classes where the corresponding data points belong

Those two arrays have to be of the same size. Moreover, there have to be at least two classes within the training data set.

The output **outSvmModel** is an SVM_Model that may be used by SVM_ClassifySingle function.

outTrainingAccuracy is the fraction of correctly classified training data points.

Errors

List of possible exceptions:

Error type	Description
DomainError	Data vector cannot be empty in SVM_Train.
DomainError	Incompatible array sizes in SVM_Train
DomainError	Incompatible vector sizes in SVM_Train.
DomainError	Incorrect or uninitialized SvmModel in Svm_Train.
DomainError	SM model is already trained in SVM_Train.

136. Image Relations

Table of content:

- TestBoxInImage
- TestImageEqualTo
- TestLocationInBox
- TestLocationInImage
- TestPointInImage
- TestRectangleInImage

TestBoxInImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a box is contained in the dimensions of an image.

Syntax

```
void avl::TestBoxInImage
(
 const avl::Image& inImage,
 const avl::Box& inBox,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inBox	const Box&		
←	outIsContained	bool&		

Description

Tests whether a box is contained in the dimensions of an image.

Examples

TestBoxInImage Output	Preview
True	
False	
TestImageEqualTo

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether two images equal.

Syntax

```
void avl::TestImageEqualTo
(
 const avl::Image& inImage,
 const avl::Image& inReferenceImage,
 bool& outIsEqual
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inReferenceImage	const Image&		
←	outIsEqual	bool&		

Also in AVL Lite

TestLocationInBox

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a location is contained in the dimensions of a box.

Syntax

```
void avl::TestLocationInBox
(
 const avl::Location& inLocation,
 const avl::Box& inBox,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inLocation	const Location&		
→	inBox	const Box&		
←	outIsContained	bool&		

Also in AVL Lite

TestLocationInImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a location is contained in the dimensions of an image.

Syntax

```
void avl::TestLocationInImage
(
 const avl::Image& inImage,
 const avl::Location& inLocation,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inLocation	const Location&		
←	outIsContained	bool&		

Also in AVL Lite

TestPointInImage

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a point is contained in the dimensions of an image.

Syntax

```
void avl::TestPointInImage
(
 const avl::Image& inImage,
 const avl::Point2D& inPoint,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inPoint	const Point2D&		
←	outIsContained	bool&		

TestRectangleInImage

Also in AVL Lite

Header: AVL.h
Namespace: avl
Module: FoundationLite

Tests whether a rectangle is contained in the dimensions of an image.

Syntax

```
void avl::TestRectangleInImage
(
 const avl::Image& inImage,
 const avl::Rectangle2D& inRectangle,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
→	inRectangle	const Rectangle2D&		
←	outIsContained	bool&		

137. Histogram Relations

Table of content:

- TestHistogramDominatesHistogram

TestHistogramDominatesHistogram

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Checks whether the values in the first histogram are greater or equal than corresponding values in the second histogram.

Syntax

```
void avl::TestHistogramDominatesHistogram
(
 const avl::Histogram& inHistogram1,
 const avl::Histogram& inHistogram2,
 bool& outDominates
)
```

Parameters

	Name	Type	Default	Description
➡	inHistogram1	const Histogram&		Input histogram1
➡	inHistogram2	const Histogram&		Input histogram2
⬅	outDominates	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Input histograms formats are not the same in TestHistogramDominatesHistogram.

138. Geometry 3D Relations

Table of content:

- TestLine3DThroughCircle3D
- TestPoint3DInBox3D

TestLine3DThroughCircle3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether a line in 3D goes through a circle in 3D.

Syntax

```
void avl::TestLine3DThroughCircle3D
(
 const avl::Line3D& inLine3D,
 const avl::Circle3D& inCircle3D,
 bool& outGoesThrough
)
```

Parameters

	Name	Type	Default	Description
→	inLine3D	const Line3D&		
→	inCircle3D	const Circle3D&		
←	outGoesThrough	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Indefinite circle on input in TestLine3DThroughCircle3D.
DomainError	Indefinite line on input in TestLine3DThroughCircle3D.

TestPoint3DInBox3D

Header: AVL.h
Namespace: avl
Module: Vision3DLite

Tests whether a point in 3D lies in a box in 3D.

Syntax

```
void avl::TestPoint3DInBox3D
(
 const avl::Point3D& inPoint3D,
 const avl::Box3D& inBox3D,
 bool& outIsContained
)
```

Parameters

	Name	Type	Default	Description
→	inPoint3D	const Point3D&		
→	inBox3D	const Box3D&		
←	outIsContained	bool&		

139. Profile Relations

Table of content:

- TestProfileDominatesProfile
- TestProfileEqualTo

TestProfileDominatesProfile

Header: AVL.h
Namespace: avl
Module: FoundationPro

Checks whether values in the first profile are greater or equal than corresponding values in the second profile.

Syntax

```
void avl::TestProfileDominatesProfile
(
 const avl::Profile& inProfile1,
 const avl::Profile& inProfile2,
 bool& outDominates
)
```

Parameters

	Name	Type	Default	Description
→	inProfile1	const Profile&		Input profile1
→	inProfile2	const Profile&		Input profile2
←	outDominates	bool&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Input profiles have different lengths in TestProfileDominatesProfile.
DomainError	Input profiles have different X coordinates in TestProfileDominatesProfile.

TestProfileEqualTo

Header: AVL.h
Namespace: avl
Module: FoundationPro

Checks whether profiles are exactly equals.

Syntax

```
void avl::TestProfileEqualTo
(
 const avl::Profile& inProfile,
 const avl::Profile& inReferenceProfile,
 bool& outIsEqual
)
```

Parameters

	Name	Type	Default	Description
→	inProfile	const Profile&		Input profile
→	inReferenceProfile	const Profile&		
←	outIsEqual	bool&		

140. WebSocket

Table of content:

- WebSocket_Close
- WebSocket_Connect
- WebSocket_ReadBuffer
- WebSocket_ReadText
- WebSocket_WriteBuffer
- WebSocket_WriteText

WebSocket_Close

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Closes a WebSocket connection.

Syntax

```
void avl::WebSocket_Close
(
 const avl::WebSocketId& inWebSocket
)
```

Parameters

	Name	Type	Default	Description
→	inWebSocket	const WebSocketId&		Socket ID.

WebSocket_Connect

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Connects to a remote server using WebSocket protocol.

Syntax

```
void avl::WebSocket_Connect
(
 avl::WebSocketConnectionState& ioState,
 const atl::String& inHostName,
 atl::Optional<int> inTimeout,
 atl::Optional<int> inReadBufferSize,
 bool inAllowUntrusted,
 const atl::Optional<atl::File>& inCaCertFile,
 atl::Conditional<avl::WebSocketId>& outWebSocket
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	WebSocketConnectionState&			Object used to maintain state of the function.
→	inHostName	const String&		\"ws://\"	URL address of the remote server.
→	inTimeout	Optional<int>	0 – ∞	NIL	Request timeout in seconds.
→	inReadBufferSize	Optional<int>		NIL	Read buffer size.
→	inAllowUntrusted	bool		False	Whether or not to allow untrusted SSL certificates.
→	inCaCertFile	const Optional<File>&		NIL	File holding one or more certificates to verify the peer with.
←	outWebSocket	Conditional<WebSocketId>&			Connected socket ID.

WebSocket_ReadBuffer

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Receives a byte buffer from a connected WebSocket.

Syntax

```
void avl::WebSocket_ReadBuffer
(
 const avl::WebSocketId& inWebSocket,
 atl::Optional<int> inTimeout,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Default	Description
→	inWebSocket	const WebSocketId&		Socket ID.
→	inTimeout	Optional<int>	NIL	Timeout in milliseconds.
←	outBuffer	ByteBuffer&		Received byte buffer.

WebSocket_ReadText

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Receives a string from a connected WebSocket.

Syntax

```
void avl::WebSocket_ReadText
(
 const avl::WebSocketId& inWebSocket,
 atl::Optional<int> inTimeout,
 atl::String& outText
)
```

Parameters

	Name	Type	Default	Description
→	inWebSocket	const WebSocketId&		Socket ID.
→	inTimeout	Optional<int>	NIL	Timeout in milliseconds.
←	outText	String&		Received string.

WebSocket_WriteBuffer

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Outputs a byte buffer through a connected WebSocket.

Syntax

```
void avl::WebSocket_WriteBuffer
(
 const avl::WebSocketId& inWebSocket,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Default	Description
➡	inWebSocket	const WebSocketId&		Socket ID.
➡	inBuffer	const ByteBuffer&		Input byte buffer.

WebSocket_WriteText

Header: AVL.h
Namespace: avl
Module: FoundationBasic

Outputs a string through a connected WebSocket.

Syntax

```
void avl::WebSocket_WriteText
(
 const avl::WebSocketId& inWebSocket,
 const atl::String& inText
)
```

Parameters

	Name	Type	Default	Description
➡	inWebSocket	const WebSocketId&		Socket ID.
➡	inText	const String&		Input string.

141. Loop Generators

Table of content:

- EnumerateCombinations
- EnumerateIntegerPairs
- EnumerateIntegers
- EnumerateRealPairs
- EnumerateReals

EnumerateCombinations

Header: STD.h
Namespace: avl
Module: FoundationLite

In each consecutive iteration produces a consecutive combination of integer numbers.

Syntax

```
bool avl::EnumerateCombinations
(
 EnumerateCombinationsState& ioState,
 int inCombinationSize,
 int inSetSize,
 bool inRepeat,
 atl::Array<int>& outCombination,
 int& outIndex
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	EnumerateCombinationsState&			Object used to maintain state of the function.
→	inCombinationSize	int	0 – ∞	2	
→	inSetSize	int	0 – ∞	3	
→	inRepeat	bool			Determines whether to repeat loop
←	outCombination	Array<int>&			
←	outIndex	int&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Combination size cannot be greater than the set size in EnumerateCombinations.

EnumerateIntegerPairs

Header: STD.h
Namespace: avl
Module: FoundationLite

Produces a total number of 'inCount1 * inCount2' of pairs of integer numbers.

Syntax

```
bool avl::EnumerateIntegerPairs
(
 Enumerate2DState& ioState,
 int inStart1,
 atl::Optional<int> inCount1,
 int inStep1,
 int inStart2,
 int inCount2,
 int inStep2,
 bool inRepeat,
 int& outValue1,
 int& outValue2
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Enumerate2DState&			Object used to maintain state of the function.
	inStart1	int			First element of first range
	inCount1	Optional<int>	0 – ∞	NIL	Length of first range
	inStep1	int			Difference between consecutive elements of first range
	inStart2	int			First element of second range
	inCount2	int	0 – ∞		Length of second range
	inStep2	int			Difference between consecutive elements of second range
	inRepeat	bool			Determines whether to repeat loop
	outValue1	int&			Elements of first range in 'AAABBBCCC' order
	outValue2	int&			Elements of second range in 'ABCABCABC' order

EnumerateIntegers

Header: STD.h
Namespace: avl
Module: FoundationLite

In each consecutive iteration produces a consecutive number from an arithmetic sequence.

Syntax

```
bool avl::EnumerateIntegers
(
 Enumerate1DState& ioState,
 int inStart,
 atl::Optional<int> inCount,
 int inStep,
 bool inRepeat,
 int& outValue,
 atl::Optional<bool> outIsFirst = atl::NIL,
 atl::Optional<bool> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	Enumerate1DState&			Object used to maintain state of the function.
→	inStart	int			First value of the generated sequence
→	inCount	Optional<int>	0 – ∞	NIL	Length of the generated sequence
→	inStep	int			Value added in each iteration
→	inRepeat	bool			Determines whether to repeat loop
←	outValue	int&			
←	outIsFirst	Optional<bool>		NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool>		NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

EnumerateRealPairs

Header: STD.h
Namespace: avl
Module: FoundationLite

Produces a total number of 'inCount1 * inCount2' of pairs of real numbers.

Syntax

```
bool avl::EnumerateRealPairs
(
 Enumerate2DState& ioState,
 float inStart1,
 atl::Optional<int> inCount1,
 float inStep1,
 float inStart2,
 int inCount2,
 float inStep2,
 bool inRepeat,
 float& outValue1,
 float& outValue2
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Enumerate2DState&			Object used to maintain state of the function.
→	inStart1	float			First element of first range
→	inCount1	Optional<int>	0 – ∞	NIL	Length of first range
→	inStep1	float			Difference between consecutive elements of first range
→	inStart2	float			First element of second range
→	inCount2	int	0 – ∞		Length of second range
→	inStep2	float			Difference between consecutive elements of second range
→	inRepeat	bool			Determines whether to repeat loop
←	outValue1	float&			Elements of first range in 'AAABBBCCC' order
←	outValue2	float&			Elements of second range in 'ABCABCABC' order

EnumerateReals

Header: STD.h
Namespace: avl
Module: FoundationLite

In each consecutive iteration produces a consecutive number from an arithmetic sequence.

Syntax

```
bool avl::EnumerateReals
(
 Enumerate1DState& ioState,
 float inStart,
 atl::Optional<int> inCount,
 float inStep,
 bool inRepeat,
 float& outValue,
 atl::Optional<bool> outIsFirst = atl::NIL,
 atl::Optional<bool> outIsLast = atl::NIL
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Enumerate1DState&			Object used to maintain state of the function.
→	inStart	float			First value of the generated sequence
→	inCount	Optional<int>	0 – ∞	NIL	Length of the generated sequence
→	inStep	float			Value added in each iteration
→	inRepeat	bool			Determines whether to repeat loop
←	outValue	float&			
←	outIsFirst	Optional<bool>		NIL	Flag indicating the first iteration
←	outIsLast	Optional<bool>		NIL	Flag indicating the last iteration

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outIsFirst**, **outIsLast**.

Read more about Optional Outputs.

142. Matrix

Table of content:

- AddMatrices
- CombineMatrices
- ConcatenateMatrices
- CreateIdentityMatrix
- CreateUniformMatrix
- InvertMatrix
- LoadMatrix
- MultiplyMatrices
- MultiplyMatrixByReal
- SaveMatrix
- StackMatrices
- SubtractMatrices
- TransposeMatrix

AddMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds two matrices element by element.

Syntax

```
void avl::AddMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix dimensions do not match in AddMatrices.

Also in AVL Lite

CombineMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Combines two matrices horizontally.

Syntax

```
void avl::CombineMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot combine matrices which do not have equal number of rows!

ConcatenateMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Combines two matrices horizontally.

Syntax

```
void avl::ConcatenateMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix row counts do not match in ConcatenateMatrices.

Also in AVL Lite

CreateIdentityMatrix

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a square matrix with ones on the main diagonal, and zeros elsewhere.

Syntax

```
void avl::CreateIdentityMatrix
(
 int inSize,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSize	int	1 – ∞		
←	outMatrix	Matrix&			

CreateUniformMatrix

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates a matrix with the specified dimensions and filled with a uniform element value.

Syntax

```
void avl::CreateUniformMatrix
(
 int inRowCount,
 int inColumnCount,
 float inValue,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Range	Default	Description
→	inRowCount	int	0 – ∞		
→	inColumnCount	int	0 – ∞		
→	inValue	float			
←	outMatrix	Matrix&			

InvertMatrix

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Finds the inverse of a square matrix.

Syntax

```
void avl::InvertMatrix
(
 const avl::Matrix& inMatrix,
 avl::Matrix& outInverseMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
←	outInverseMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty matrix in MatrixInverse
DomainError	Non-square matrix in MatrixInverse

LoadMatrix

Header: STD.h
Namespace: avl
Module: FoundationLite

Loads a serialized Matrix object from an AVDATA file.

Syntax

```
void avl::LoadMatrix
(
 const atl::File& inFilename,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inFilename	const File&		Name of the source file
←	outMatrix	Matrix&		Deserialized Matrix

Also in AVL Lite

MultiplyMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Multiplies two matrices element by element.

Syntax

```
void avl::MultiplyMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix dimensions incompatible in MultiplyMatrices.

MultiplyMatrixByReal

Header: STD.h
Namespace: avl
Module: FoundationLite

Multiplies all elements of a matrix by a value.

Syntax

```
void avl::MultiplyMatrixByReal
(
 const avl::Matrix& inMatrix,
 float inValue,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
→	inValue	float		
←	outMatrix	Matrix&		

Also in AVL Lite

SaveMatrix

Header: STD.h
Namespace: avl
Module: FoundationLite

Saves a serialized Matrix object as AVDATA file.

Syntax

```
void avl::SaveMatrix
(
 const avl::Matrix& inMatrix,
 const atl::File& inFilename
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		Matrix to be serialized
→	inFilename	const File&		Name of the target file

StackMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Combines two matrices vertically.

Syntax

```
void avl::StackMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix column counts do not match in StackMatrices.

Also in AVL Lite

SubtractMatrices

Header: STD.h
Namespace: avl
Module: FoundationLite

Subtracts two matrices element by element.

Syntax

```
void avl::SubtractMatrices
(
 const avl::Matrix& inMatrix1,
 const avl::Matrix& inMatrix2,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix1	const Matrix&		
→	inMatrix2	const Matrix&		
←	outMatrix	Matrix&		

Errors

List of possible exceptions:

Error type	Description
DomainError	Matrix dimensions do not match in SubtractMatrices.

TransposeMatrix

Header: STD.h
Namespace: avl
Module: FoundationLite

Swaps rows with columns in a matrix.

Syntax

```
void avl::TransposeMatrix
(
 const avl::Matrix& inMatrix,
 avl::Matrix& outTranspose
)
```

Parameters

	Name	Type	Default	Description
→	inMatrix	const Matrix&		
←	outTranspose	Matrix&		

143. Time

Table of content:

- AddDurations
- AddToTimestamp
- CreateDuration
- CurrentDateTime
- CurrentTime
- DateTimeToTimestamp
- Delay
- DelayByPeriod
- FormatDateTimeToString
- GetClockTime
- MeasurePeriod
- SplitDurationToParts
- StartClock
- SubtractDurations
- SubtractFromTimestamp
- SubtractTimestamps
- TimestampDifference
- TimestampToDateTime
- TimestampToUnixTime
- UnixTimeToTimestamp

AddDurations

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes sum of two durations.

Syntax

```
void avl::AddDurations
(
 const avl::Duration& inDuration1,
 const avl::Duration& inDuration2,
 avl::Duration& outDuration
)
```

Parameters

	Name	Type	Default	Description
→	inDuration1	const Duration&		
→	inDuration2	const Duration&		
←	outDuration	Duration&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

AddToTimestamp

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Shifts timestamp forward by a given duration.

Syntax

```
void avl::AddToTimestamp
(
 const avl::Timestamp& inTimestamp,
 const avl::Duration& inDuration,
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp	const Timestamp&		
→	inDuration	const Duration&		
←	outTimestamp	Timestamp&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Also in AVL Lite

CreateDuration

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates duration from its components.

Syntax

```
void avl::CreateDuration
(
 double inDays,
 double inHours,
 double inMinutes,
 double inSeconds,
 double inNanoseconds,
 avl::Duration& outDuration
)
```

Parameters

	Name	Type	Default	Description
→	inDays	double		
→	inHours	double		
→	inMinutes	double		
→	inSeconds	double		
→	inNanoseconds	double		
←	outDuration	Duration&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Also in AVL Lite

CurrentDateTime

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns current date and time in multiple formats.

Applications: Combines the most commonly used date and time filters into one tool.

Syntax

```
void avl::CurrentDateTime
(
 avl::TimezoneKind::Type inTimezone,
 const atl::String& inFormat,
 const int inDecimalPlaces,
 const atl::String& inLocale,
 avl::Timestamp& outTimestamp,
 avl::DateTime& outDateTime,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inTimezone	TimezoneKind::Type			Timezone to convert to
→	inFormat	const String&		\"%x %X\"	Date and time format to use
→	inDecimalPlaces	const int	0 - 9		Number of decimal places to use when printing seconds
→	inLocale	const String&			Locale to use when converting
←	outTimestamp	Timestamp&			Current UTC timestamp
←	outDateTime	DateTime&			Date and time in selected timezone
←	outString	String&			Date and time converted to string

Description

inFormat string can contain format specifiers which will be replaced with corresponding values. The most commonly used format specifiers are:

Specifier	Example output	Description
%a	Sun	locale-dependent weekday name, short
%A	Sunday	locale-dependent weekday name, long
%b	Jan	locale-dependent month name, short
%B	January	locale-dependent month name, long
%c	1/31/2021 3:04:05 PM	locale-dependent date and time. Warning: on some locales it can also print current timezone name, which may be different from timezone in passed DateTime object.
%C	20	year divided by 100
%d	31	day of month, <01;31>
%H	15	hour, <00;23>
%I	03	hour, <01;12>
%m	01	month, <01;12>
%M	04	minute, <00;59>
%p	PM	"AM" or "PM" (locale-dependent)
%r	3:04:05 PM	locale-dependent 12-hour time
%S	05.6780000	seconds, <00;59>, use **inDecimalPlaces** to set precision (decimal separator is locale-dependent)
%u	7	weekday, <1;7> (Sunday is 7)
%w	0	weekday, <0;6> (Sunday is 0)
%x	1/31/2021	locale-dependent date
%X	3:04:05 PM	locale-dependent time
%y	21	last two digits of year, <00;99>
%Y	2021	year (left padded with "0" to 4 digits)
%z	+0500	offset from UTC, e.g. "+0500" for UTC+5 timezone
%Z	local	timezone name: "UTC" if offset is 0, otherwise "local"
%%	%	"%" character

For a full list of format specifiers, see https://howardhinnant.github.io/date/date.html#to_stream_formatting.

inLocale can be used to choose how locale-dependent values are formatted. It can have values such as:

Locale	Example output for format "%x, %A"	Description
(empty string)	2021-01-31, niedziela	use locale set as system default
C	01/31/21, Sunday	use "C locale"
de_DE.utf8	31.01.2021, Sonntag	German language in Germany
pt_BR.utf8	31/01/2021, domingo	Portuguese language in Brazil

Note that the requested locale must be installed on the operating system.

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Couldn't convert time to local timezone This could mean the date is out of supported range. Set inTimezone to UTC to skip the conversion.
SystemError	Couldn't find locale: exception message

Also in AVL Lite

CurrentTime

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns current UTC timestamp.

Syntax

```
void avl::CurrentTime
(
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Default	Description
⬅	outTimestamp	Timestamp&		UTC timestamp

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

DateTimeToTimestamp

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts date and time to UTC timestamp.

Syntax

```
void avl::DateTimeToTimestamp
(
 const avl::DateTime& inDateTime,
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Default	Description
→	inDateTime	const DateTime&		Date and time with timezone offset
←	outTimestamp	Timestamp&		UTC timestamp

Remarks

inDateTime.DayOfWeek field is ignored and computed from the other fields.

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Errors

List of possible exceptions:

Error type	Description
DomainError	Date or time field out of range

Also in AVL Lite

Delay

Header: STD.h
Namespace: avl
Module: FoundationLite

Suspends the program workflow for inTime milliseconds.

Syntax

```
void avl::Delay
(
 int inTime
)
```

Parameters

	Name	Type	Range	Default	Description
→	inTime	int	0 – 10000	100	Target time in milliseconds

Description

This filter suspends the program workflow for **inTime** milliseconds.

See Also

- DelayByPeriod – Suspends the program workflow for inTime milliseconds relative to the end of the filter's last invoke time.
- MeasurePeriod – Returns elapsed time in milliseconds from last filter call.

Also in AVL Lite

DelayByPeriod

Header: STD.h
Namespace: avl
Module: FoundationLite

Suspends the program workflow for inTime milliseconds relative to the end of the filter's last invoke time.

Syntax

```
void avl::DelayByPeriod
(
 DelayByPeriodState& ioState,
 int inTime
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	DelayByPeriodState&			Object used to maintain state of the function.
→	inTime	int	0 – 10000	100	Target period in milliseconds

Description

This filter suspends the program workflow for **inTime** milliseconds relative to the end of the filter's last invoke time.

See Also

- Delay – Suspends the program workflow for inTime milliseconds.
- MeasurePeriod – Returns elapsed time in milliseconds from last filter call.

Also in AVL Lite

FormatDateTimeToString

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns a string containing date and time information in selected format.

Syntax

```
void avl::FormatDateTimeToString
(
 const avl::DateTime& inDateTime,
 const atl::String& inFormat,
 const int inDecimalPlaces,
 const atl::String& inLocale,
 atl::String& outString
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDateTime	const DateTime&			Date and time with timezone offset
→	inFormat	const String&		\"%x %X\"	Date and time format to use
→	inDecimalPlaces	const int	0 - 9		Number of decimal places to use when printing seconds
→	inLocale	const String&			Locale to use when converting
←	outString	String&			Date and time converted to string

Description

inFormat string can contain format specifiers which will be replaced with corresponding values. The most commonly used format specifiers are:

Specifier	Example output	Description
%a	Sun	locale-dependent weekday name, short
%A	Sunday	locale-dependent weekday name, long
%b	Jan	locale-dependent month name, short
%B	January	locale-dependent month name, long
%c	1/31/2021 3:04:05 PM	locale-dependent date and time. Warning: on some locales it can also print current timezone name, which may be different from timezone in passed DateTime object.
%C	20	year divided by 100
%d	31	day of month, <01;31>
%H	15	hour, <00;23>
%I	03	hour, <01;12>
%m	01	month, <01;12>
%M	04	minute, <00;59>
%p	PM	"AM" or "PM" (locale-dependent)
%r	3:04:05 PM	locale-dependent 12-hour time
%S	05.6780000	seconds, <00;59>, use **inDecimalPlaces** to set precision (decimal separator is locale-dependent)
%u	7	weekday, <1;7> (Sunday is 7)
%w	0	weekday, <0;6> (Sunday is 0)
%x	1/31/2021	locale-dependent date
%X	3:04:05 PM	locale-dependent time
%y	21	last two digits of year, <00;99>
%Y	2021	year (left padded with "0" to 4 digits)
%z	+0500	offset from UTC, e.g. "+0500" for UTC+5 timezone
%Z	local	timezone name: "UTC" if offset is 0, otherwise "local"
%%	%	"%" character

For a full list of format specifiers, see https://howardhinnant.github.io/date/date.html#to_stream_formatting.

inLocale can be used to choose how locale-dependent values are formatted. It can have values such as:

Locale	Example output for format "%x, %A"	Description
(empty string)	2021-01-31, niedziela	use locale set as system default
C	01/31/21, Sunday	use "C locale"
de_DE.utf8	31.01.2021, Sonntag	German language in Germany
pt_BR.utf8	31/01/2021, domingo	Portuguese language in Brazil

Note that the requested locale must be installed on the operating system.

Remarks

inDateTime.DayOfWeek field is ignored and computed from the other fields.

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Errors

List of possible exceptions:

Error type	Description
DomainError	Date or time field out of range
DomainError	Invalid inDecimalPlaces value
SystemError	Couldn't find locale: exception message

GetClockTime

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Stops clock to measure performance.

Syntax

```
void avl::GetClockTime
(
 const avl::ClockTime& inStartTime,
 double& outElapsedTime
)
```

Parameters

	Name	Type	Default	Description
→	inStartTime	const ClockTime&		Start time - use StartClock filter
←	outElapsedTime	double&		Time in milliseconds from inStartTime

MeasurePeriod

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns elapsed time in milliseconds from last filter call.

Syntax

```
void avl::MeasurePeriod
(
 MeasureState& ioState,
 float& outTime,
 float& outFrequency
)
```

Parameters

	Name	Type	Default	Description
	ioState	MeasureState&		Object used to maintain state of the function.
	outTime	float&		Elapsed time in milliseconds
	outFrequency	float&		The resulting frequency in Hz or FPS

Description

This filter returns elapsed time **outTime** in milliseconds from it's last call.

The **outFrequency** is the momentary frequency in Hz, i.e. iterations per second.

Remarks

On the first call of this filter, the returned values of **outTime** and **outFrequency** are zero.

See Also

- DelayByPeriod – Suspends the program workflow for inTime milliseconds relative to the end of the filter's last invoke time.
- Delay – Suspends the program workflow for inTime milliseconds.

SplitDurationToParts

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes components of a duration.

Syntax

```
void avl::SplitDurationToParts
(
 const avl::Duration& inDuration,
 int& outDaysPart,
 int& outHoursPart,
 int& outMinutesPart,
 int& outSecondsPart,
 int& outNanosecondsPart,
 double& outTotalDays,
 double& outTotalHours,
 double& outTotalMinutes,
 double& outTotalSeconds,
 double& outTotalNanoseconds
)
```

Parameters

	Name	Type	Default	Description
→	inDuration	const Duration&		Duration to split
←	outDaysPart	int&		Integer number of days
←	outHoursPart	int&		Integer number of hours (in range <-23;23>)
←	outMinutesPart	int&		Integer number of minutes (in range <-59;59>)
←	outSecondsPart	int&		Integer number of seconds (in range <-59;59>)
←	outNanosecondsPart	int&		Integer number of nanoseconds (in range <-999999999;999999999>)
←	outTotalDays	double&		Total duration expressed in days
←	outTotalHours	double&		Total duration expressed in hours
←	outTotalMinutes	double&		Total duration expressed in minutes
←	outTotalSeconds	double&		Total duration expressed in seconds
←	outTotalNanoseconds	double&		Total duration expressed in nanoseconds

Remarks

Note the subtle difference between **outDaysPart**, **outHoursPart**, ... outputs and **outTotalDays**, **outTotalHours**, ... outputs. For example, let us assume a duration of 28.5 hours.

- If one needs to do calculations on it, like dividing by 2, use **outTotalHours** output or any other Total output.
- If one needs to display the duration to the user as hours, minutes and seconds (like "28:30:00"); use integer part of **outTotalHours** together with **outMinutesPart** and **outSecondsPart**. That way the hours part will not overflow if the duration is longer than one day.

Note that if a negative duration is provided, every output will also be negative or equal to zero.

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

StartClock

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Starts clock to measure performance.

Syntax

```
void avl::StartClock
(
 avl::ClockTime& outStartTime
)
```

Parameters

	Name	Type	Default	Description
←	outStartTime	ClockTime&		Start time

SubtractDurations

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes signed difference between two durations.

Syntax

```
void avl::SubtractDurations
(
 const avl::Duration& inDuration1,
 const avl::Duration& inDuration2,
 avl::Duration& outDuration
)
```

Parameters

	Name	Type	Default	Description
→	inDuration1	const Duration&		
→	inDuration2	const Duration&		
←	outDuration	Duration&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

SubtractFromTimestamp

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Shifts timestamp backward by a given duration.

Syntax

```
void avl::SubtractFromTimestamp
(
 const avl::Timestamp& inTimestamp,
 const avl::Duration& inDuration,
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp	const Timestamp&		
→	inDuration	const Duration&		
←	outTimestamp	Timestamp&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

SubtractTimestamps

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes time elapsed between first and second timestamp (signed).

Syntax

```
void avl::SubtractTimestamps
(
 const avl::Timestamp& inTimestamp1,
 const avl::Timestamp& inTimestamp2,
 avl::Duration& outDuration
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp1	const Timestamp&		
→	inTimestamp2	const Timestamp&		
←	outDuration	Duration&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

TimestampDifference

Header: STD.h
Namespace: avl
Module: FoundationLite

Computes absolute value of time elapsed between two timestamps.

Syntax

```
void avl::TimestampDifference
(
 const avl::Timestamp& inTimestamp1,
 const avl::Timestamp& inTimestamp2,
 avl::Duration& outDuration
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp1	const Timestamp&		
→	inTimestamp2	const Timestamp&		
←	outDuration	Duration&		

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

TimestampToDateTime

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts UTC timestamp to date and time in selected timezone.

Syntax

```
void avl::TimestampToDateTime
(
 const avl::Timestamp& inTimestamp,
 avl::TimezoneKind::Type inTimezone,
 avl::DateTime& outDateTime
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp	const Timestamp&		UTC timestamp
→	inTimezone	TimezoneKind::Type		Timezone to convert to
←	outDateTime	DateTime&		Date and time in selected timezone

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Couldn't convert time to local timezone This could mean the date is out of supported range. Set inTimezone to UTC to skip the conversion.

TimestampToUnixTime

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts timestamp to Unix time.

Syntax

```
void avl::TimestampToUnixTime
(
 const avl::Timestamp& inTimestamp,
 atl::int64& outUnixTime,
 int& outNanoseconds
)
```

Parameters

	Name	Type	Default	Description
→	inTimestamp	const Timestamp&		UTC timestamp
←	outUnixTime	int64&		Unix time (seconds part)
←	outNanoseconds	int&		Nanoseconds part, in range <0;999999999>

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

UnixTimeToTimestamp

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts Unix time to timestamp.

Syntax

```
void avl::UnixTimeToTimestamp
(
 const atl::sint64 inUnixTime,
 int inNanoseconds,
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Default	Description
→	inUnixTime	const sint64		Unix time (seconds part)
→	inNanoseconds	int		Nanoseconds part, in range <0;999999999>
←	outTimestamp	Timestamp&		UTC timestamp

Remarks

Assumptions about date and time calculations:

- Timestamp should always be in UTC (Coordinated Universal Time).
- Timestamp can be converted to DateTime using either UTC or local timezone. Other timezones are not supported. However, the timezone offset is saved in DateTime so one can always convert back to UTC.
- Conversion to local time should take into account daylight saving time (summer/winter time), if configured in the operating system. However, usually only currently applicable DST rules are used, so calculations may be incorrect if they refer to a period when the rules were different.
- Timestamp resolution is 100 nanoseconds.
- Timestamp is 64-bit, so should support dates about 29000 years in the past or future. However, the whole range may not be supported when converting to local timezone.
- Dates are calculated in proleptic Gregorian calendar.
- Leap seconds are ignored, like in Unix time.

144. Process

Table of content:

- ReadEnvironmentVariable
- ReadEnvironmentVariable_OrNil

ReadEnvironmentVariable

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads environment variable by given name.

Syntax

```
void avl::ReadEnvironmentVariable
(
 const atl::String& inVariableName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inVariableName	const String&		Variable name to be read
←	outValue	String&		Variable value

Errors

List of possible exceptions:

Error type	Description
IoError	Variable: 'Variable name' was not found.

Also in AVL Lite

ReadEnvironmentVariable_OrNil

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads environment variable by given name.

Syntax

```
void avl::ReadEnvironmentVariable_OrNil
(
 const atl::String& inVariableName,
 atl::Conditional<atl::String>& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inVariableName	const String&		Variable name to be read
←	outValue	Conditional<String>&		Variable value or nil

145. Python

Table of content:

- Python_CallFunction

Python_CallFunction

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Calls a function from a Python module

Syntax

```
void avl::Python_CallFunction
(
 const atl::File& inModulePath,
 const atl::String& inFunctionName,
 atl::Optional<const avl::PythonObject&> inArg1,
 atl::Optional<const avl::PythonObject&> inArg2,
 atl::Optional<const avl::PythonObject&> inArg3,
 atl::Optional<const avl::PythonObject&> inArg4,
 atl::Optional<const avl::PythonObject&> inArg5,
 atl::Optional<const avl::PythonObject&> inArg6,
 atl::Optional<avl::PythonObject&> outResult1,
 atl::Optional<avl::PythonObject&> outResult2,
 atl::Optional<avl::PythonObject&> outResult3,
 atl::Optional<avl::PythonObject&> outResult4
)
```

Parameters

	Name	Type	Default	Description
→	inModulePath	const File&		Path to a Python source module file (.py file)
→	inFunctionName	const String&		Name of the Python function to call
→	inArg1	Optional<const PythonObject&>	NIL	
→	inArg2	Optional<const PythonObject&>	NIL	
→	inArg3	Optional<const PythonObject&>	NIL	
→	inArg4	Optional<const PythonObject&>	NIL	
→	inArg5	Optional<const PythonObject&>	NIL	
→	inArg6	Optional<const PythonObject&>	NIL	
←	outResult1	Optional<PythonObject&>		
←	outResult2	Optional<PythonObject&>		
←	outResult3	Optional<PythonObject&>		
←	outResult4	Optional<PythonObject&>		

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outResult1**, **outResult2**, **outResult3**, **outResult4**.

Read more about Optional Outputs.

Description

This filter allows to utilize/interface with Python scripts and libraries by calling a function in a Python module while passing its arguments and retrieving its results through filter input and output ports.

For this filter to work it is required to separately **install the Python runtime version 3.12 in the system** with installation path added to the system environment variables. Currently the filter is only supported on the Windows operating system.

inModulePath input specifies a path to a Python module/script file to be loaded (the path must point to a file with .py extension). This module will be loaded into the Python environment created in the background only once over a vision program execution. Upon load the top level part of the script will be executed allowing to initialize the scripts global state and prepare any custom environment. The module will stay loaded and the global state of the module will be preserved (even after exiting a Task macrofilter) up until the vision program stops. Subsequent calls to the same filter instance or other instances of the Python_CallFunction filters pointing to the same python script file will invoke the already loaded module. Thus it is possible to contain additional work state in Pythons global variables and refer to it from various Python functions from various Python_CallFunction filter instances.

After the vision program stops and starts again all modules are unloaded and the global Python state is reset. Note that to reset the Python environment state when working from Adaptive Vision Library programmers interface the avl::Python_Cleanup() function can be used.

inFunctionName specifies the name of the function to be invoked. This name must point to a Python function existing in the top level namespace of the specified Python script module.

inArg1 to **inArg6** inputs provide input arguments for the function call. Objects from those inputs are passed to the function in order as positional arguments. Leaving the input on its default (Auto) value means that the argument is not used. The inputs must be set in consecutive order starting from **inArg1**. Setting the inputs in non-consecutive order (e.g. leaving **inArg2** but setting the **inArg3** input) will result in a DomainError.

outResult1 to **outResult4** outputs are retrieving the object returned by the Python code from the function. When the function returns a Tuple it is unpacked and its items are assigned in order to the **outResult1** to **outResult4** outputs. When the returned tuple contains less than 4 items the remaining filter outputs are set to None. Attempt to return more than 4 items in a tuple will result in a RuntimeError. When the function returns an object different than Tuple it is assigned to the **outResult1** output and the remaining outputs are set to None.

Data conversion

All data inputs and outputs caring function call arguments and results are of special built-in type **PythonObject**. This type can hold some of the Pythons built-in types and provides implicit conversion to and from vision program types. As a result it is possible to simply connect data of arbitrary supported types to the Python_CallFunction argument inputs to pass such data to the Python environment and to connect a result object from the arguments output to an input of anticipated type to convert the Python objects back to the vision program types.

The following Python built-in types and their convertible vision program equivalents are supported:

Python type	Program type(s)
Boolean (bool)	Bool
Integer (int)	Integer, Long
Real (float)	Real, Double
String (text)	String
List of Boolean objects	BoolArray
List of Integer objects	IntegerArray, LongArray
List of Real objects[1]	RealArray, DoubleArray
List of String objects	StringArray
None	See Conditional Data

Connecting data of one of the above program types to the argument input will create an object of equivalent Python type that will be passed as the function argument.

When connecting data from the results output the type returned by the Python code must be anticipated and a connection must be made to an input of equivalent program type. Returning a type not listed in the above table from the Python function will result in a DomainError. When the object returned by the Python function is not compatible with the connected program type a DomainError will be raised **at the connected inputs filter at program runtime**. Similar conversion DomainError will be raised when a numeric value returned from the Python code **is out of the supported range** of the destination program type.

Special care must be taken when returning list objects from the function call. Python allows to mix object types in the list items, but in order to convert such list to a program array all its items must be of the same type. Attempt to return a list with items of mixed types will result in a DomainError.

[1]) When returning a list with mixed Real and Integer objects from a python function the entire list is considered to be a list of Reals and implicitly converted to real arrays for the vision application.

Conditional Data

By default the argument inputs and result outputs do not support conditional data. Connecting conditional types on argument inputs will result in a conditional execution of the filter and returning empty data from the result outputs will fail to convert to program data.

To pass a conditional data into the Python function the ConditionalToPythonObject filter must be used first on a connection to the argument input. Non-Nil data will be converted without change, as described above. Nil value from the program will be passed to the Python function argument as a None object and must be handled by the Python code accordingly.

To retrieve a conditional data from the function the PythonObjectToConditional filter must be used on a connection from the result output. When the Python function return a None object (or passes a None object as a returned tuple item) it will be converted to Nil on a conditional output of the PythonObjectToConditional. Other than None objects will be converted without change, as described above and returned as non-Nil conditional data.

Logging

This filter, on initialization, will install a handler to the standard Python logging facilities that will redirect the logging messages from the Python code to the Adaptive Vision Studio console and log file. For example, calling below function using the filter:

```
import logging

def myTestFunction():
    logging.getLogger().warning("This is a warning log!")
```

will result in the following log record in the console:

```
10:30:00 | Warning | [Python] This is a warning log!
```

The "[Python]" prefix is added by default by the handlers formatter, which can be customized from the Python script (e.g. at the script initialization) by modifying the properties of a handler identified by the name "AVSLogHandler". For example:

```
logging.getHandlerByName("AVSLogHandler").setFormatter(logging.Formatter('This is a %(levelname)s log from a Python script: "%(message)s"'))
```

Logging level is left on the default settings and can also be modified from the Python script during the initialization. For example, to see the log messages at info level:

```
logging.getLogger().setLevel(logging.INFO)
```

Logging messages are redirected to the console only from the thread that performs the function call from the filter and only during the filter execution. Log messages sent from the threads started separately in the python scripts will not be redirected.

Exception handling

All not handled exceptions thrown by the Python code during the function call will result in the filter causing a RuntimeError with the description formatted from the Python exception.

Failure to load the Python script file (module) on filters first execution, even as a result of a not handled exception in the top-level initialization code, will result in the filter causing an IOError.

Platform support

This operation is only supported on the Microsoft Windows operating system.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty Python function name specified.
DomainError	Empty Python module file path specified.
DomainError	Python function call arguments provided in a non-consecutive way.
RuntimeError	Too many result arguments returned by the Python function call.

146. Random

Table of content:

- CreateRandomArray
- CreateRandomMatrix
- RandomInteger
- RandomReal
- ShuffleArray

CreateRandomArray

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates array with random values.

Syntax

```
void avl::CreateRandomArray
(
 const int inLength,
 const float inMinValue,
 const float inMaxValue,
 const float inStep,
 atl::Optional<int> inSeed,
 atl::Array<float>& outArray
)
```

Parameters

	Name	Type	Range	Default	Description
→	inLength	const int	0 – +∞	10	Length of output array
→	inMinValue	const float			Minimal generated value
→	inMaxValue	const float		10.0f	Maximal generated value
→	inStep	const float	0.0001 – ∞	1.0f	Minimal difference between two generated values
→	inSeed	Optional<int>		NIL	Random seed used to generate values
←	outArray	Array<float>&			

Remarks

This filter should not be used for generating cryptographically secure random numbers.

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inLength is negative.
DomainError	Value of inMinValue is greater than value of inMaxValue.
DomainError	Value of inStep is greater than span between maximal and minimal value.
DomainError	Values inMinValue and inMaxValue are equal.

CreateRandomMatrix

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates matrix with random values in closed interval.

Syntax

```
void avl::CreateRandomMatrix
(
 const int inColumnCount,
 const int inRowCount,
 const float inMinValue,
 const float inMaxValue,
 const float inStep,
 atl::Optional<int> inSeed,
 avl::Matrix& outMatrix
)
```

Parameters

	Name	Type	Range	Default	Description
→	inColumnCount	const int		10	Columns count of generated matrix
→	inRowCount	const int		10	Rows count of generated matrix
→	inMinValue	const float			Minimal generated value
→	inMaxValue	const float		10.0f	Maximal generated value
→	inStep	const float	0.0001 – ∞	1.0f	Minimal difference between two random values
→	inSeed	Optional<int>		NIL	Random seed used to generate values
←	outMatrix	Matrix&			

Remarks

This filter should not be used for generating cryptographically secure random numbers.

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inColumnCount is non-positive.
DomainError	Value of inMinValue is greater than value of inMaxValue.
DomainError	Value of inRowCount is non-positive.
DomainError	Value of inStep is greater than span between maximal and minimal value.
DomainError	Values inMinValue and inMaxValue are equal.

RandomInteger

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates random integer value in given closed interval.

Syntax

```
void avl::RandomInteger
(
 RandomState& ioState,
 const int inMinValue,
 const int inMaxValue,
 atl::Optional<int> inSeed,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RandomState&		Object used to maintain state of the function.
→	inMinValue	const int		Minimal generated value
→	inMaxValue	const int	10	Maximal generated value
→	inSeed	Optional<int>	NIL	Random seed used to generate values
←	outValue	int&		

Remarks

This filter should not be used for generating cryptographically secure random numbers.

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inMinValue is greater than value of inMaxValue.
DomainError	Values inMinValue and inMaxValue are equal.

RandomReal

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates random real value in given closed interval.

Syntax

```
void avl::RandomReal
(
 RandomState& ioState,
 const float inMinValue,
 const float inMaxValue,
 atl::Optional<int> inSeed,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	RandomState&		Object used to maintain state of the function.
→	inMinValue	const float		Minimal generated value
→	inMaxValue	const float	1.0f	Maximal generated value
→	inSeed	Optional<int>	NIL	Random seed used to generate values
←	outValue	float&		

Remarks

This filter should not be used for generating cryptographically secure random numbers.

Errors

List of possible exceptions:

Error type	Description
DomainError	Value of inMinValue is greater than value of inMaxValue.

ShuffleArray

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Creates an array by setting input array values in the random positions.

Syntax

```
void avl::ShuffleArray
(
 const atl::Array<Type>& inArray,
 atl::Optional<int> inSeed,
 atl::Array<Type>& outArray
)
```

Parameters

	Name	Type	Default	Description
→	inArray	const Array<Type>&		Array to shuffle
→	inSeed	Optional<int>	NIL	Random seed used to generate values
←	outArray	Array<Type>&		

Remarks

This filter should not be used for generating cryptographically secure random numbers.

147. Unit Conversions

Table of content:

- DegreesToRadians
- MillimetresToPixels
- PixelsToMillimetres
- RadiansToDegrees

Also in AVL Lite

DegreesToRadians

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts degrees to radians.

Syntax

```
void avl::DegreesToRadians
(
 float inDegrees,
 float& outRadians
)
```

Parameters

	Name	Type	Default	Description
→	inDegrees	float		
←	outRadians	float&		

Also in AVL Lite

MillimetresToPixels

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts a length in millimetres to pixels using the given scale [px / mm].

Syntax

```
void avl::MillimetresToPixels
(
 float inMillimetres,
 float inScale,
 float& outPixels
)
```

Parameters

	Name	Type	Default	Description
→	inMillimetres	float		
→	inScale	float		px / mm
←	outPixels	float&		

Also in AVL Lite

PixelsToMillimetres

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts a length in pixels to millimetres using the given scale [px / mm].

Syntax

```
void avl::PixelsToMillimetres
(
 float inPixels,
 float inScale,
 float& outMillimetres
)
```

Parameters

	Name	Type	Default	Description
→	inPixels	float		
→	inScale	float		px / mm
←	outMillimetres	float&		

Also in AVL Lite

RadiansToDegrees

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts radians to degrees.

Syntax

```
void avl::RadiansToDegrees
(
 float inRadians,
 float& outDegrees
)
```

Parameters

	Name	Type	Default	Description
→	inRadians	float		
←	outDegrees	float&		

148. User Input

Table of content:

- GetKeyboardKeys
- GetKeyboardKeyState

GetKeyboardKeys

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Returns virtual key codes of the pressed keys or NULL if no key was pressed.

Syntax

```
void avl::GetKeyboardKeys
(
 const bool inNumKeypad,
 const bool inAlpha,
 const bool inSpecial,
 const bool inFKeys,
 atl::Array<int>& outKeyCodes
)
```

Parameters

	Name	Type	Default	Description
→	inNumKeypad	const bool	True	Determines whether to analyze keys from numeric keypad
→	inAlpha	const bool	True	Determines whether to analyze keys from alphanumeric keypad
→	inSpecial	const bool		Determines whether to analyze special keys
→	inFKeys	const bool		Determines whether to analyze functional keys (F1 to F24)
←	outKeyCodes	Array<int>&		Virtual key codes of the pressed keys. See documentation for a complete table

Remarks

For complete list of virtual key codes, please follow the link below:
https://docs.microsoft.com/windows/desktop/inputdev/virtual-key-codes

Platform support

This operation is only supported on the Microsoft Windows operating system.

See Also

- GetKeyboardKeyState – Checks if the specified keyboard key is down and if it is toggled.

GetKeyboardKeyState

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Checks if the specified keyboard key is down and if it is toggled.

Syntax

```
void avl::GetKeyboardKeyState
(
 const int inKeyCode,
 bool& outIsDown,
 bool& outIsToggled
)
```

Parameters

	Name	Type	Default	Description
→	inKeyCode	const int		Virtual key code. See documentation for a complete table.
←	outIsDown	bool&		Informs if the specified keyboard key is being pressed at the moment.
←	outIsToggled	bool&		Informs about the state. Important for keys such as CapsLock.

Remarks

For complete list of virtual key codes, please follow the link below:
https://docs.microsoft.com/windows/desktop/inputdev/virtual-key-codes

Platform support

This operation is only supported on the Microsoft Windows operating system.

See Also

- GetKeyboardKeys - Returns virtual key codes of the pressed keys or NULL if no key was pressed.

149. INI

Table of content:

- INI_AddBoolValue
- INI_AddIntegerValue
- INI_AddRealValue
- INI_AddSection
- INI_AddStringValue
- INI_GetAllSectionKeys
- INI_GetAllSections
- INI_GetAllValues
- INI_GetBoolValue
- INI_GetIntegerValue
- INI_GetRealValue
- INI_GetStringValue
- INI_LoadFile
- INI_SaveFile

INI_AddBoolValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds or updates an INI value in the specified section & key.

Syntax

```
void avl::INI_AddBoolValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const bool inValue,
 atl::Optional<const atl::String&> inComment,
 bool inMultipleValues,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inValue	const bool		Key value
→	inComment	Optional<const String&>	NIL	Optional comment
→	inMultipleValues	bool	False	Allow multiple values in one key
←	outINI	String&		

INI_AddIntegerValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds or updates an INI value in the specified section & key.

Syntax

```
void avl::INI_AddIntegerValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const int inValue,
 atl::Optional<const atl::String&> inComment,
 bool inMultipleValues,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inValue	const int		Key value
→	inComment	Optional<const String&>	NIL	Optional comment
→	inMultipleValues	bool	False	Allow multiple values in one key
←	outINI	String&		

INI_AddRealValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds or updates an INI value in the specified section & key.s

Syntax

```
void avl::INI_AddRealValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const float inValue,
 atl::Optional<const atl::String&> inComment,
 bool inMultipleValues,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inValue	const float		Key value
→	inComment	Optional<const String&>	NIL	Optional comment
→	inMultipleValues	bool	False	Allow multiple values in one key
←	outINI	String&		

Also in AVL Lite

INI_AddSection

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds a new section.

Syntax

```
void avl::INI_AddSection
(
 const atl::String& inINI,
 const atl::String& inSection,
 atl::Optional<const atl::String&> inComment,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inComment	Optional<const String&>	NIL	Optional comment
←	outINI	String&		

INI_AddStringValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Adds or updates an INI value in the specified section & key.

Syntax

```
void avl::INI_AddStringValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const atl::String& inValue,
 atl::Optional<const atl::String&> inComment,
 bool inMultipleValues,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inValue	const String&		Key value
→	inComment	Optional<const String&>	NIL	Optional comment
→	inMultipleValues	bool	False	Allow multiple values in one key
←	outINI	String&		

Also in AVL Lite

INI_GetAllSectionKeys

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets all key names within a section.

Syntax

```
void avl::INI_GetAllSectionKeys
(
 const atl::String& inINI,
 const atl::String& inSectionName,
 atl::Array<atl::String>& outKeys
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSectionName	const String&		Section name
←	outKeys	Array<String>&		

INI_GetAllSections

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets all section names in the INI.

Syntax

```
void avl::INI_GetAllSections
(
 const atl::String& inINI,
 atl::Array<atl::String>& outSections
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
←	outSections	Array<String>&		

Also in AVL Lite

INI_GetAllValues

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets all values within a section & key.

Syntax

```
void avl::INI_GetAllValues
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 atl::Array<atl::String>& outValues
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
←	outValues	Array<String>&		

INI_GetBoolValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets value from section & key.

Syntax

```
void avl::INI_GetBoolValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const bool inDefault,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inDefault	const bool		Value to return if the key is not found
←	outValue	bool&		

Also in AVL Lite

INI_GetIntegerValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets value from section & key.

Syntax

```
void avl::INI_GetIntegerValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const int inDefault,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inDefault	const int		Value to return if the key is not found
←	outValue	int&		

INI_GetRealValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets value from section & key.

Syntax

```
void avl::INI_GetRealValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const float inDefault,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inDefault	const float		Value to return if the key is not found
←	outValue	float&		

Also in AVL Lite

INI_GetStringValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Gets value from section & key.

Syntax

```
void avl::INI_GetStringValue
(
 const atl::String& inINI,
 const atl::String& inSection,
 const atl::String& inKey,
 const atl::String& inDefault,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inSection	const String&		Section name
→	inKey	const String&		Key name
→	inDefault	const String&		Value to return if the key is not found
←	outValue	String&		

INI_LoadFile

Header: STD.h
Namespace: avl
Module: FoundationLite

Loads an INI file.

Syntax

```
void avl::INI_LoadFile
(
 const atl::File& inFile,
 bool inMultipleValues,
 atl::String& outINI
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		Path to the source file
→	inMultipleValues	bool	True	Allow multiple values in one key
←	outINI	String&		

Also in AVL Lite

INI_SaveFile

Header: STD.h
Namespace: avl
Module: FoundationLite

Saves an INI file.

Syntax

```
void avl::INI_SaveFile
(
 const atl::String& inINI,
 bool inMultipleValues,
 const atl::File& inFile
)
```

Parameters

	Name	Type	Default	Description
→	inINI	const String&		INI
→	inMultipleValues	bool	False	Allow multiple values in one key
→	inFile	const File&		Path to a file

150. Binary Data

Table of content:

- LoadBuffer
- SaveBuffer

Also in AVL Lite

LoadBuffer

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads bytes from a file and returns them as a bytes buffer.

Syntax

```
void avl::LoadBuffer
(
 const atl::File& inFile,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Default	Description
→	inFile	const File&		
←	outBuffer	ByteBuffer&		

Errors

List of possible exceptions:

Error type	Description
IoError	File is too large for byte buffer.

Also in AVL Lite

SaveBuffer

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes bytes from a byte buffer to a file.

Syntax

```
void avl::SaveBuffer
(
 const avl::ByteBuffer& inBuffer,
 avl::FileAccessMode::Type inFileAccessMode,
 const atl::File& inFile,
 bool inIgnoreErrors
)
```

Parameters

	Name	Type	Default	Description
→	inBuffer	const ByteBuffer&		
→	inFileAccessMode	FileAccessMode::Type	CreateOrErase	
→	inFile	const File&		
→	inIgnoreErrors	bool

ModbusTCP_Close

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Closes a connected Modbus socket gracefully.

Syntax

```
void avl::ModbusTCP_Close
(
 avl::SocketId inSocket
)
```

Parameters

	Name	Type	Default	Description
➡	inSocket	SocketId		Connected socket Id.

Hints

- Connect **inSocket** with the output of ModbusTCP_Connect.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ModbusTCP_Connect – Connects as a client to a remote Modbus server socket.

ModbusTCP_Connect

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Connects as a client to a remote Modbus server socket.

Syntax

```
void avl::ModbusTCP_Connect
(
 TcpIpConnectState& ioState,
 const atl::String& inHost,
 int inPort,
 const atl::Optional<int>& inTimeout,
 const atl::Optional<int>& inKeepAliveTime,
 atl::Conditional<avl::SocketId>& outSocket
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	TcpIpConnectState&			Object used to maintain state of the function.
→	inHost	const String&		\"localhost\"	The hostname or IP address to connect to.
→	inPort	int	7 – 65535	502	Modbus port of host to connect to. 502 is the default one.
→	inTimeout	const Optional<int>&	500 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inKeepAliveTime	const Optional<int>&	2000 – ∞	NIL	When specified activates Tcp/Ip keep alive on new socket with given idle time.
←	outSocket	Conditional<SocketId>&			Connected socket ID.

Description

For more details please check help of TcpIp_Connect filter. The filters works in the same way.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ModbusTCP_Close – Closes a connected Modbus socket gracefully.

ModbusTCP_ForceMultipleCoils

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 15. Forces each coil in a sequence of coils to either ON or OFF in a remote device

Syntax

```
void avl::ModbusTCP_ForceMultipleCoils
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 const atl::Array<bool>& inStatuses
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first coil.
→	inStatuses	const Array<bool>&			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Size of statuses array should be between 1 and 1968.

- ModbusTCP_WriteCoil – Function Code 05. Writes a single output to either ON or OFF in a remote device

ModbusTCP_ReadCoils

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 01. Reads contiguous status of coils in a remote device

Syntax

```
void avl::ModbusTCP_ReadCoils
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inBitCount,
 atl::Array<bool>& outBits
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Unit identifier.
→	inStartingAddress	int	0 – 65535		The address of the first coil.
→	inBitCount	int	1 – 2000	1	Requested number of bits.
←	outBits	Array<bool>&			Response.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ModbusTCP_WriteCoil – Function Code 05. Writes a single output to either ON or OFF in a remote device

ModbusTCP_ReadDiscreteInputs

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 02. Reads contiguous status of discrete inputs in a remote device

Syntax

```
void avl::ModbusTCP_ReadDiscreteInputs
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inBitCount,
 atl::Array<bool>& outBits
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first input.
→	inBitCount	int	1 – 2000	1	Requested number of bits.
←	outBits	Array<bool>&			Response.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_ReadExceptionStatus

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 07. Attempts to read Exception Status

Syntax

```
void avl::ModbusTCP_ReadExceptionStatus
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int& outStatus
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1
←	outStatus	int&			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	Received message length is too short.

ModbusTCP_ReadInputIntegerRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 04. Reads contiguous input registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadInputIntegerRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 avl::ModbusDataFormat::Type inInputDataFormat,
 atl::Array<int>& outIntegerValues
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1
→	inStartingAddress	int	0 – 65535		The address of the first input register.
→	inCount	int	1 – 125	1	
→	inInputDataFormat	ModbusDataFormat::Type			
←	outIntegerValues	Array<int>&			Received integer values

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ModbusTCP_ReadInputRealRegisters – Function Code 04. Reads contiguous input registers in a remote device

ModbusTCP_ReadInputRealRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 04. Reads contiguous input registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadInputRealRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 atl::Array<float>& outRealValues
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first input register.
→	inCount	int	1 – 125	1	
←	outRealValues	Array<float>&			Received real values.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

ModbusTCP_ReadInputRegisters_AsByteBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 03. Reads contiguous input registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadInputRegisters_AsByteBuffer
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 avl::ByteBuffer& outData
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first input register.
→	inCount	int	1 – 125	1	Number of registers to read. Each register is 2 Bytes in size
←	outData	ByteBuffer&			Received register values.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ModbusTCP_ReadInputRealRegisters – Function Code 04. Reads contiguous input registers in a remote device

ModbusTCP_ReadMultipleIntegerRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 03. Reads the contents of a contiguous block of holding registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadMultipleIntegerRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 avl::ModbusDataFormat::Type inInputDataFormat,
 atl::Array<int>& outIntegerValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first holding register.
→	inCount	int	1 – 125	1	
→	inInputDataFormat	ModbusDataFormat::Type			
←	outIntegerValue	Array<int>&			Received integer value.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_ReadMultipleRealRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 03. Reads the contents of a contiguous block of holding registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadMultipleRealRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 atl::Array<float>& outRealValue
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first holding register.

ModbusTCP_ReadMultipleRegisters_AsByteBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 03. Reads the contents of a contiguous block of holding registers in a remote device

Syntax

```
void avl::ModbusTCP_ReadMultipleRegisters_AsByteBuffer
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 int inCount,
 avl::ByteBuffer& outData
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first holding register.
→	inCount	int	1 – 125	1	Number of registers to read. Each register is 2 Bytes in size.
←	outData	ByteBuffer&			Received register values.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_SendBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Sends data using Modbus TCP frame format.

Syntax

```
void avl::ModbusTCP_SendBuffer
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inFunctionCode,
 const avl::ByteBuffer& inBuffer,
 avl::ByteBuffer& outResponse
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1
→	inFunctionCode	int	0 – 255	1	Function code
→	inBuffer	const ByteBuffer&			Data to send
←	outResponse	ByteBuffer&			Response data

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_WriteCoil

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 05. Writes a single output to either ON or OFF in a remote device

Syntax

```
void avl::ModbusTCP_WriteCoil
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inOutputAddress,
 bool inStatus
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSocket	const SocketId&			Connected socket ID on port 502.
➡	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
➡	inUnitID	int	0 – 255	1	Default is 1
➡	inOutputAddress	int	0 – 65535		The address of the coil to be forced.
➡	inStatus	bool			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

ModbusTCP_WriteMultipleIntegerRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 16. Writes a block of contiguous registers (1 to 123 registers) in a remote device

Syntax

```
void avl::ModbusTCP_WriteMultipleIntegerRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 const atl::Array<int>& inIntegerValues,
 avl::ModbusDataFormat::Type inDataFormat
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSocket	const SocketId&			Connected socket ID on port 502.
➡	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
➡	inUnitID	int	0 – 255	1	Default is 1
➡	inStartingAddress	int	0 – 65535		The address of the first register.
➡	inIntegerValues	const Array<int>&			Integer values to set
➡	inDataFormat	ModbusDataFormat::Type			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_WriteMultipleRealRegisters

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 16. Writes a block of contiguous registers (1 to 123 registers) in a remote device

Syntax

```
void avl::ModbusTCP_WriteMultipleRealRegisters
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 const atl::Array<float>& inRealValues
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first register.
→	inRealValues	const Array<float>&			Real values to set.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_WriteMultipleRegisters_AsByteBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 16. Writes a block of contiguous registers (1 to 123 registers) in a remote device

Syntax

```
void avl::ModbusTCP_WriteMultipleRegisters_AsByteBuffer
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inStartingAddress,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	const SocketId&			Connected socket ID on port 502.
→	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inUnitID	int	0 – 255	1	Default is 1.
→	inStartingAddress	int	0 – 65535		The address of the first register.
→	inBuffer	const ByteBuffer&			Buffer with values to set.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

ModbusTCP_WriteSingleRegister

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Function Code 06. Writes a single holding register in a remote device

Syntax

```
void avl::ModbusTCP_WriteSingleRegister
(
 const avl::SocketId& inSocket,
 const atl::Optional<int>& inTimeout,
 int inUnitID,
 int inRegisterAddress,
 int inValue
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inSocket	const SocketId&			Connected socket ID on port 502.
➡	inTimeout	const Optional<int>&	10 – ∞	NIL	Timeout in milliseconds, block if not specified.
➡	inUnitID	int	0 – 255	1	Default is 1.
➡	inRegisterAddress	int	0 – 65535		The address of the holding register to be written.
➡	inValue	int	0 – 65535		Value to send.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

OPCUAClient_Close

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Closes a connection with a OPC UA server.

Syntax

```
void avl::OPCUAClient_Close
(
 int inConnectionId
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the connection to close

Description

This filter is used to close a connection with a OPC UA server previously open with the OPCUAClient_Connect filter.

The value on the **inConnectionId** input must correspond to the connection slot id specified in the connect filter.

This filter will not throw exceptions when the connection is not established or when there were any errors during the connection closing procedure.

OPCUAClient_Connect

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Establishes a connection to a OPC UA server

Syntax

```
void avl::OPCUAClient_Connect
(
 int inConnectionId,
 const atl::String& inEndpointURI,
 const atl::String& inUserName,
 const atl::String& inPassword,
 avl::OpcUaSecurityMode::Type inSecurityMode,
 bool inExtendedLogging
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id to keep this connection in and distinguish from other connections in the application
➡	inEndpointURI	const String&			Server endpoint URI to connect to
➡	inUserName	const String&			
➡	inPassword	const String&			
➡	inSecurityMode	OpcUaSecurityMode::Type			
➡	inExtendedLogging	bool		False	Enables additional (debug) logging of the OPC UA client activity

Description

This filter initializes a local instance of a OPC UA client and establishes a connection with a remote OPC UA server over a OPC TCP binary protocol.

The **inConnectionId** input can be used when working with multiple server connections at once. The value at this input determines an internal slot that the connection is held in and that other OPC UA Client filters can refer to. The connect filter can be invoked multiple times with different values on the **inConnectionId** input to open multiple connections. Invoking the filter more than once on the same connection id, without closing the connection first, will result in a DomainError exception. When working with a single OPC UA connection this input can be left on its default value in all OPC UA Client filters.

The mandatory **inEndpointURI** input specifies the full URI of the server endpoint to connect to. This URI will usually start with "opc.tcp://".

The **inSecurityMode** specifies the requested Security Mode configuration of the connection and can be set to one of the values: "None", "Sign", "SignAndEncrypt", as defined by the OPC UA standard. Setting this input to None (default) will result in no message encryption or signing, and no server security certificate verification. **Setting this input to "Sign" or "SignAndEncrypt" requires for the local OPC UA client security to be set up first using the OPCUAClient_SetupSecurityCertificates filter (invoked before the connect filter).**

The **inUserName** and **inPassword** inputs pair can be used to authenticate the client identity for the connection session, using the User Name Identity Token. When both inputs are left empty the client will attempt to use the Anonymous Identity Token. **Please note that some servers might require the client security to be configured (using the OPCUAClient_SetupSecurityCertificates filter) for the User Name Identity authentication to be possible.**

To diagnose and resolve server connection problems the **inExtendedLogging** input can be set to True. In this mode the OPC UA client will Log in the console additional diagnostic information about connection state changes or mode negotiation.

After successful invocation of the connect filter other filters from the OPC UA category can be used, with the same connection id, to read or write values from/to the OPC UA server.

To close the connection the OPCUAClient_Close filter can be used on the same connection id. All OPC UA connections will also be closed automatically when the vision application is stopped.

Errors

This filter will throw an IOError exception on any network connection problem or server connection negotiation error.

List of possible exceptions:

Error type	Description
DomainError	Empty server endpoint URI in OPCUAClient_Connect.
DomainError	Requesting OPC UA security mode other than None without security certificates configured. Use OPCUAClient_SetupSecurityCertificates before OPCUAClient_Connect.
DomainError	User credentials password provided without the user name in OPCUAClient_Connect.

OPCUAClient_ReadBoolValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a Boolean value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadBoolValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<bool>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<bool>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of: Boolean, SByte, Byte (or derived from those). The value is internally converted to Bool and returned on the **outValue** output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadByteBufferValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a ByteString compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadByteBufferValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<avl::ByteBuffer>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<ByteBuffer>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data type of ByteString or types derived from it. The value is internally converted to ByteBuffer and returned on the **outValue** output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadDoubleValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a Double compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadDoubleValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<double>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<double>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of Float and Double (or derived from those). The value is internally converted to Double and returned on the **outValue** output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadIntegerArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads an Integer compatible array value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadIntegerArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<atl::Array<int>>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<Array<int>>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar or array variables with OPC UA basic data types of: SByte, Byte, Int16, UInt16, Int32, UInt32, StatusCode, Boolean, *Enum* (or derived from those). The value is internally converted to IntegerArray and returned on the **outValue** output. Scalar values are returned as an array with a single element.

Please note that when reading a variable of the UInt32 OPC UA type its value will be converted to the internal signed 32bit Integer type without a range check, and its large values can wrap around to a negative result on the output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadIntegerValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads an up to 32bit Integer compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadIntegerValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<int>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<int>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of: SByte, Byte, Int16, UInt16, Int32, UInt32, StatusCode, *Enum* (or derived from those). The value is internally converted to Integer and returned on the **outValue** output.

Please note that when reading a variable of the UInt32 OPC UA type its value will be converted to the internal signed 32bit Integer type without a range check, and its large values can wrap around to a negative result on the output. To avoid this problem the OPCUAClient_ReadLongValue filter can be used.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

Also in **AVL Lite**

OPCUAClient_ReadLongValue

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads an up to 64bit Integer compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadLongValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<atl::int64>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<int64>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of: SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, StatusCode, DateTime, UtcTime (or derived from those). The value is internally converted to Long and returned on the **outValue** output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadRealArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a Float compatible array value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadRealArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<atl::Array<float>>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<Array<float>>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar or array variables with OPC UA basic data types of Float and Double (or derived from those). The value is internally converted to RealArray and returned on the **outValue** output. Scalar values are returned as an array with a single element.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadRealValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a Float compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadRealValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<float>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<float>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of Float and Double (or derived from those). The value is internally converted to Real and returned on the **outValue** output.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadStringArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a String compatible array value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadStringArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<atl::Array<atl::String>>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<Array<String>>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar or array variables with OPC UA basic data types of: String, LocalizedText, XmlElement, Guid (or derived from those). The value is internally converted to StringArray and returned on the **outValue** output. Scalar values are returned as an array with a single element. When reading values of type LocalizedText only the Text field is retrieved (the Locale field is ignored). When reading values of type Guid, the guid is converted into a textual representation in the "XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX" format.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_ReadStringValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads a String compatible value of a variable node from a OPC UA server.

Syntax

```
void avl::OPCUAClient_ReadStringValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 bool inAcceptBadStatus,
 atl::Conditional<atl::String>& outValue,
 int& outStatusCode,
 atl::int64& outSourceTimestamp,
 atl::int64& outServerTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 – 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to read the value from
→	inAcceptBadStatus	bool		False	Accept variable value read Bad status code without generating an error
←	outValue	Conditional<String>&			The value read from the variable node
←	outStatusCode	int&			OPC UA status code of the variable value reported by the server
←	outSourceTimestamp	int64&			OPC UA UtcTime value source timestamp reported by the server
←	outServerTimestamp	int64&			OPC UA UtcTime server timestamp

Description

This filter is used to read a value of the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to read the value from (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

When the **inAcceptBadStatus** input is set to false, the filter will throw an IOError exception when the value read operation on the server fails or when the StatusCode, currently associated with the value on the server, is in the "Bad" severity range. When this input is set to true, the filter will throw an exception only on connection related errors and will finish successfully even when the read operation fails (e.g. the node id does not exists or the user has no access rights to read it), or when the value usability StatusCode is in the "Bad" severity range. In this case the StatusCode identifying the error will be reported on the **outStatusCode** output. This mode can be helpful when explicitly handling the value usability status (e.g. the value not yet set condition).

The read value is returned on the **outValue** output. This output has a conditional type and can return Nil when the source value on the server is equal to Null. Please note that the OPC UA data model allows for the value to be equal to Null on multiple levels (e.g. null string in a variant, or null variant). This filter does not distinguish those levels and returns a single conditional value that is equal to Nil in all those cases. When the **inAcceptBadStatus** is set to true, this output can also return Nil on read operation failure or when the value usability status severity is "Bad".

The **outSourceTimestamp** and **outServerTimestamp** outputs return timestamps associated with the value on the server. When the server does not supports the appropriate timestamp zero is returned in its place. Timestamps format is defined by the OPC UA UtcTime data type (number of 100 nanosecond intervals since January 1, 1601 Coordinated Universal Time). The OPCUATimestampToTimestamp filter can be used to convert it into Timestamp in order to be further processed.

This filter can access scalar variables with OPC UA basic data types of: String, LocalizedText, XmlElement, Guid (or derived from those). The value is internally converted to String and returned on the **outValue** output. When reading values of type LocalizedText only the Text field is retrieved (the Locale field is ignored). When reading values of type Guid, the guid is converted into a textual representation in the "XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX" format.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and read operation errors.

OPCUAClient_SetupSecurityCertificates

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Configures the security layers of OPC UA client to server connections for this application

Syntax

```
void avl::OPCUAClient_SetupSecurityCertificates
(
 const atl::String& inApplicationURI,
 const atl::File& inApplicationCertificate,
 const atl::File& inPrivateKey,
 const atl::Directory& inTrustedCertStore,
 const atl::Directory& inIssuerCertStore,
 const atl::Directory& inRevokedCertStore,
 avl::OpcUaCertificateHandling::Type inCertificateAction
)
```

Parameters

	Name	Type	Default	Description
➡	inApplicationURI	const String&		The URI identifying this application instance that the certificate refers to
➡	inApplicationCertificate	const File&		Path to this applications public certificate file
➡	inPrivateKey	const File&		Path to this applications private key file
➡	inTrustedCertStore	const Directory&		Path to the directory containing trusted certificate files (.crt, .pem or .der files)
➡	inIssuerCertStore	const Directory&		Path to the directory containing certificate files of trusted certificate issuers (.crt, .pem or .der files)
➡	inRevokedCertStore	const Directory&		Path to the directory containing revoked certificate list files for certificate issuers (.crl files)
➡	inCertificateAction	OpcUaCertificateHandling::Type	Verify	Local application certificate verification and creation action to take during the security settings initialization

Description

This filter must be invoked before OPCUAClient_Connect filters when encryption, signing and/or client/server identity verification is required on the OPC UA connections. Only one instance of this filter is required in the program, even when working with multiple OPC UA connections.

The purpose of this filter is to set up the client's security certificate, security related configuration and the server certificate verification chain.

All certificates referenced to this filter (both client certificate and server verification chain) must be in the X.509 version 3 format and stored in files in PEM or DER container formats.

Please note that this filter performs minimal verifications of the input data and certificate contents. Most configuration and/or certificate related errors will manifest itself during the connection attempt (after invoking the OPCUAClient_Connect filter).

The **inApplicationURI** input (required) must specify the OPC UA Application URI that the client will identify itself with to the server. This URI is usually specified in the Uniform Resource Name (URN) format (e.g. "urn:my_application_domain:my_application_name"). This URI must match the URI in the Subject Alternative Name field of the client application certificate.

The **inApplicationCertificate** and **inPrivateKey** inputs (required) specify paths to the application public certificate and the private key files accordingly.

The **inTrustedCertStore** input (required) specifies a path to the directory containing trusted certificate files. All files with extension .pem, .der, .cer and .crt in this directory are loaded and considered trusted when verifying the server certificates.

The **inIssuerCertStore** input (optional) specifies a path to the directory containing issuers certificate files. All files with extension .pem, .der, .cer and .crt in this directory are loaded and used in verification of server certificates.

The **inRevokedCertStore** input (required when **inIssuerCertStore** is specified) specifies a path to the directory containing certificate revocation list files. A single revocation file must have the extension .crl and must correspond to a single issuer certificate in the issuers certificate store.

The **inCertificateAction** input determines if this filter should perform verification of the local application certificate and private key pair specified by the **inApplicationCertificate** and **inPrivateKey** inputs, and what actions to perform depending of the verification results:

- **None** - This filter will not attempt to load and will not perform any verification of the application certificate. Lack of the certificate files or invalid certificate will still result in an error during a connection attempt.
- **Verify** - This filter will load and verify the application public certificate and private key for validity, consistency with the OPC UA requirements and consistency with the application configuration. Missing files and verification errors will be immediately reported with an IOError exception.
- **VerifyAndCreateMissing** - similar to **Verify**, but when the public certificate file does not exists this filter, instead of reporting an error, will attempt to generate a new public certificate and private key pair, and save them in the files specified on the **inApplicationCertificate** and **inPrivateKey** inputs (see below for details). The filter will still report an error when the certificate exists and is invalid.
- **VerifyAndRecreateExpired** - similar to **VerifyAndCreateMissing**, but the public certificate and private key will also be automatically recreated and overridden when the existing (and otherwise valid) certificate is expired.

When automatically creating a new application certificate this filter will create a self signed certificate with 2048bit RSA key, valid for 5 years and compatible with the application URI specified on the **inApplicationURI** input. This certificate will have to be manually trusted on the OPC UA server after automatic creation or recreation.

Errors

This filter will throw a DomainError exception when any of the required inputs is left empty or when any of the certificate store directories, pointed to by the inputs, does not exists, and IOError exception when optional local application certificate verification fails.

See Also

- OPCUAClient_Connect - Establishes a connection to a OPC UA server

OPCUAClient_WriteBoolValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a Boolean value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteBoolValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<bool>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
➡	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
➡	inValue	const Conditional<bool>&			The value to write to the variable node
➡	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of: Boolean, SByte, Byte (or derived from those), by converting the **inValue** input value of type Bool. When converting to SByte and Byte types the variable will be set to 1 for true, and 0 for false.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect - Establishes a connection to a OPC UA server
- OPCUAClient_ReadBoolValue - Reads a Boolean value of a variable node from a OPC UA server.

OPCUAClient_WriteByteBufferValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a ByteString value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteByteBufferValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<avl::ByteBuffer>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
→	inValue	const Conditional<ByteBuffer>&			The value to write to the variable node
→	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic data type of ByteString or derived from it, by converting the **inValue** input value of type ByteBuffer.

This filter can be used to send an image to the OPC UA server, by writing to variable nodes of types Image, ImageBMP, ImageJPG or ImagePNG (all deriving from the ByteString type). To achieve this the source Image must be first saved to an in-memory buffer using the SaveImageToBuffer filter, selecting the image file format appropriate for the destination node type, then writing the intermediate ByteBuffer with the stored image to the OPC UA server.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect - Establishes a connection to a OPC UA server
- OPCUAClient_ReadByteBufferValue - Reads a ByteString compatible value of a variable node from a OPC UA server.
- SaveImageToBuffer - Saves an image to a file stored in ByteBuffer.

OPCUAClient_WriteDoubleValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a Double value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteDoubleValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<double>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
→	inValue	const Conditional<double>&			The value to write to the variable node
→	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of Float and Double (or derived from those), by converting the **inValue** input value of type Double.

This filter can also write to variable nodes of the Number abstract data type, by storing the value under the Double concrete data type.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect – Establishes a connection to a OPC UA server
- OPCUAClient_ReadDoubleValue – Reads a Double compatible value of a variable node from a OPC UA server.
- OPCUAClient_WriteRealArrayValue – Writes an array of Float values to a variable node in a OPC UA server.

OPCUAClient_WriteIntegerArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes an array of Integer values to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteIntegerArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<atl::Array<int>>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
→	inValue	const Conditional<Array<int>>&			The value to write to the variable node
→	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write an array value to variables with OPC UA basic types of: SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, StatusCode, Boolean, *Enum* (or derived from those), by converting the **inValue** input value of type IntegerArray. When writing to variables of 16bit or less data types care must be taken for the source value to fit in the range of the destination variable. When at least one item in the source array is out of the range of the destination data type this filter will throw a DomainError exception.

This filter can also write to variable nodes of abstract data types: Number, Integer and UInteger. When writing to nodes typed as Number or Integer this filter will store the value under the Int32 concrete type, and under the UInt32 concrete type when writing to UInteger typed nodes.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect – Establishes a connection to a OPC UA server

- OPCUAClient_WriteRealArrayValue – Writes an array of Float values to a variable node in a OPC UA server.

OPCUAClient_WriteIntegerValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes an Integer value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteIntegerValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<int>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
→	inValue	const Conditional<int>&			The value to write to the variable node
→	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of: SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, StatusCode, *Enum* (or derived from those), by converting the **inValue** input value of type Integer. When writing to variables of 16bit or less data types care must be taken for the source value to fit in the range of the destination variable. When the source value is out of the range of the destination data type this filter will throw a DomainError exception.

This filter can also write to variable nodes of abstract data types: Number, Integer and UInteger. When writing to nodes typed as Number or Integer this filter will store the value under the Int32 concrete type, and under the UInt32 concrete type when writing to UInteger typed nodes.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect – Establishes a connection to a OPC UA server
- OPCUAClient_ReadIntegerValue – Reads an up to 32bit Integer compatible value of a variable node from a OPC UA server.
- OPCUAClient_WriteIntegerArrayValue – Writes an array of Integer values to a variable node in a OPC UA server.

OPCUAClient_WriteLongValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a 64bit Integer value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteLongValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<atl::int64>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
→	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
→	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
→	inValue	const Conditional<int64>&			The value to write to the variable node
→	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of: SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, StatusCode, DateTime, UtcTime, *Enum* (or derived from those), by converting the **inValue** input value of type Long. When writing to variables of 32bit or less data types care must be taken for the source value to fit in the range of the destination variable. When the source value is out of the range of the destination data type this filter will throw a DomainError exception.

This filter can also write to variable nodes of abstract data types: Number, Integer and UInteger. When writing to nodes typed as Number or Integer this filter will store the value under the Int64 concrete type, and under the UInt64 concrete type when writing to UInteger typed nodes.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

- OPCUAClient_WriteIntegerArrayValue – Writes an array of Integer values to a variable node in a OPC UA server.

OPCUAClient_WriteRealArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes an array of Float values to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteRealArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<atl::Array<float>>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
➡	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
➡	inValue	const Conditional<Array<float>>&			The value to write to the variable node
➡	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write an array value to variables with OPC UA basic types of Float and Double (or derived from those), by converting the **inValue** input value of type RealArray.

This filter can also write to variable nodes of the Number abstract data type, by storing the value under the Float concrete data type.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

OPCUAClient_WriteRealValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a Float value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteRealValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<float>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
➡	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
➡	inValue	const Conditional<float>&			The value to write to the variable node
➡	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of Float and Double (or derived from those), by converting the **inValue** input value of type Real.

This filter can also write to variable nodes of the Number abstract data type, by storing the value under the Float concrete data type.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect - Establishes a connection to a OPC UA server
- OPCUAClient_ReadRealValue - Reads a Float compatible value of a variable node from a OPC UA server.
- OPCUAClient_WriteRealArrayValue - Writes an array of Float values to a variable node in a OPC UA server.

OPCUAClient_WriteStringArrayValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes an array of String values to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteStringArrayValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<atl::Array<atl::String>>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
➡	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
➡	inValue	const Conditional<Array<String>>&			The value to write to the variable node
➡	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write an array value to variables with OPC UA basic types of: String, LocalizedText, XmlElement, Guid (or derived from those), by converting the **inValue** input value of type StringArray. When writing to variables of type LocalizedText only the Text field is set with the input string array item (the Locale field is left empty). When writing to variables of type Guid, the source value is expected to be a textual representation of a guid in a "XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX" format, and when at least one item in the source array does not follow this form the filter will throw an IOError exception.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

See Also

- OPCUAClient_Connect - Establishes a connection to a OPC UA server
- OPCUAClient_ReadStringArrayValue - Reads a String compatible array value of a variable node from a OPC UA server.
- OPCUAClient_WriteStringValue - Writes a String value to a variable node in a OPC UA server.

OPCUAClient_WriteStringValue

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes a String value to a variable node in a OPC UA server.

Syntax

```
void avl::OPCUAClient_WriteStringValue
(
 int inConnectionId,
 const avl::OpcUaNodeId& inNodeId,
 const atl::Conditional<atl::String>& inValue,
 int inStatus = 0
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inConnectionId	int	0 - 99	0	Slot id of the open connection to the server
➡	inNodeId	const OpcUaNodeId&			Id of the variable node to write the value to
➡	inValue	const Conditional<String>&			The value to write to the variable node
➡	inStatus	int		0	OPC UA status code for the variable value

Description

This filter is used to write (send) a value into the "Value" property of a Variable Class node on a OPC UA server.

The **inConnectionId** input specifies the server connection slot id and must correspond to the value specified in the OPCUAClient_Connect filter.

The **inNodeId** input specifies the Node Id of the server node to write the value to (see OpcUaNodeId for details). The node pointed to by this id must be of Variable class and with a compatible value data type (see below), otherwise the filter will throw an IOError exception.

The **inValue** input specifies the value to be written. This input has a conditional type. Setting the value to Nil will result in writing Null to the node's value variant.

The **inStatus** input specifies the value's usability Status Code to be assigned to the value in the server. In most cases, when writing a valid non-Null value, this input will be left on the default status of 0 (StatusCodeGood). Writing a Null value usually requires to specify a status code in the "Bad" severity range.

This filter can write a scalar value to variables with OPC UA basic types of: String, LocalizedText, XmlElement, Guid (or derived from those), by converting the **inValue** input value of type String. When writing to variables of type LocalizedText only the Text field is set with the input string (the Locale field is left empty). When writing to variables of type Guid, the source value is expected to be a textual representation of a guid in a "XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX" format, and when the source string does not follow this form the filter will throw an IOError exception.

Errors

This filter will throw an IOError exception on network connection errors, server service call errors and write operation or data conversion errors.

OPCUATimestampToTimestamp

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Converts the OPC UA DateTime timestamp value to Timestamp

Syntax

```
void avl::OPCUATimestampToTimestamp
(
 atl::int64 inOPCUATimestamp,
 avl::Timestamp& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
→	inOPCUATimestamp	int64	0 – 2650467743999999999		OPC UA DateTime timestamp value
←	outTimestamp	Timestamp&			Output timestamp

Description

The OPC UA DateTime or UtcTime timestamp data types are representing the date and time point as a 64bit number of 100 nanosecond intervals since January 1, 1601. In the vision application those data types are represented by the internal Long type.

This filter allows to convert this timestamp counter into AVS-specific Timestamp type, by taking the OPC UA DateTime value on the **inOPCUATimestamp** input and converting it to a Timestamp on the **outTimestamp** output.

The value on the **inOPCUATimestamp** input must not be negative.

Please note that this filter does not have access to the timezone of the processed date and time. In particular, this filter does not know whether the source timestamp is in UTC or in the current (server) timezone (it is assumed to be in UTC), and it needs to be taken under consideration separately when working with the output of this filter.

For further processing, see TimestampToDateTime and FormatDateTimeToString filters.

153. Serial Port

Table of content:

- SerialPort_Config
- SerialPort_ReadBuffer
- SerialPort_ReadByte
- SerialPort_ReadChar
- SerialPort_ReadString
- SerialPort_ReadStringUntil
- SerialPort_WriteBuffer
- SerialPort_WriteByte
- SerialPort_WriteChar
- SerialPort_WriteString

SerialPort_Config

Header: STD.h
Namespace: avl
Module: FoundationLite

Configures the serial port.

Syntax

```
void avl::SerialPort_Config
(
 SerialPortState& ioState,
 int inPortId,
 const atl::String& inPort,
 const int inBaudRate,
 avl::SerialPortParity::Type inParity,
 const int inDataBits,
 avl::SerialPortFlowControl::Type inFlowControl,
 avl::SerialPortStopBits::Type inStopBits,
 const int inMaxReadBufferSize
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	inPort	const String&		\"COM1\"	Serial port name
	inBaudRate	const int	1 – ∞	9600	Serial baud rate
	inParity	SerialPortParity::Type			Serial parity
	inDataBits	const int	5 – 8	8	Serial character size
	inFlowControl	SerialPortFlowControl::Type			Serial flow control
	inStopBits	SerialPortStopBits::Type			Serial stop bits
	inMaxReadBufferSize	const int	1024 – 16777216	1048576	Maximum size of internal read buffer in bytes. When the buffer reaches this size, oldest data is dropped (FIFO).

Description

Filter creates serial port connection and set its parameters.

Typically values for **inBaudRate**: 4800, 9600, 14400, 19200, 28800, 38400, 57600, 115200.

By using parameter **inPortId** up to 8 simultaneous connection can be handled. Trying to configure already created connection identified by **inPortId** will result in "Access denied" error.

Remarks

Using the SerialPort_Config filter is necessary before using other filters for serial communication.

Filter SerialPort_Config creates connection only on first execution all next execution will have no effect.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Trying to connect to port that is already opened will result in error "Could not initialize serial port. open: Access is denied".

Trying to connect to not existing port will result in error "Could not initialize serial port. open: The system cannot find the file specified".

List of possible exceptions:

Error type	Description
DomainError	Empty port name in SerialPort_Config. Empty port name is invalid. Typical port names are COM1, COM2, etc.

See Also

- SerialPort_WriteByte – Writes one character in binary mode to serial port.
- SerialPort_WriteBuffer – Writes raw binary data from a byte buffer to serial port.
- SerialPort_WriteString – Writes string characters to serial port.
- SerialPort_ReadByte – Reads one character in binary mode from serial port.
- SerialPort_ReadBuffer – Reads raw binary data from serial port.
- SerialPort_ReadChar – Reads single character from serial port.
- SerialPort_ReadString – Reads string characters from serial port.
- SerialPort_ReadStringUntil – Reads the string from the serial port to encounter a string delimiter.

SerialPort_ReadBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads raw binary data from serial port.

Syntax

```
void avl::SerialPort_ReadBuffer
(
 SerialPortState& ioState,
 int inPortId,
 atl::Conditional<avl::ByteBuffer>& outBuffer,
 bool& outOverflowOccurred
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	outBuffer	Conditional<ByteBuffer>&			Conditionally returns non empty byte buffer with raw data, when any data available.
	outOverflowOccurred	bool&			True when the internal read buffer reached its maximum size and oldest data was dropped since the last call.

Description

Filter reads all data from the serial port transmission input buffer.

Filter perform non-blocking reading form buffer and will return NIL when no data was read.

Data buffer returned on the **outBuffer** output can be processed using filters from the Binary Data category.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_ReadBuffer filter.

Filter SerialPort_Config does not guarantee that input buffer will be empty.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters reading from serial port without previous configuration will cause "SerialPort not initialized" error.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_ReadByte – Reads one character in binary mode from serial port.
- SerialPort_ReadChar – Reads single character from serial port.
- SerialPort_ReadString – Reads string characters from serial port.
- SerialPort_ReadStringUntil – Reads the string from the serial port to encounter a string delimiter.

SerialPort_ReadByte

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads one character in binary mode from serial port.

Syntax

```
void avl::SerialPort_ReadByte
(
 SerialPortState& ioState,
 int inPortId,
 atl::Conditional<int>& outData,
 bool& outOverflowOccurred
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 - 7	0	Identifies open port instance when working with multiple serial ports
	outData	Conditional<int>&			Conditionally returns received character value, when one is available.
	outOverflowOccurred	bool&			True when the internal read buffer reached its maximum size and oldest data was dropped since the last call.

Description

Filter reads single byte from input buffer.

Filter perform non-blocking reading form buffer and will return NIL when no data was read.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_ReadByte filter.

Filter SerialPort_Config does not guarantee that input buffer will be empty.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters reading from serial port without previous configuration will cause "SerialPort not initialized" error.

- SerialPort_ReadBuffer - Reads raw binary data from serial port.
- SerialPort_ReadChar - Reads single character from serial port.
- SerialPort_ReadString - Reads string characters from serial port.
- SerialPort_ReadStringUntil - Reads the string from the serial port to encounter a string delimiter.

SerialPort_ReadChar

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads single character from serial port.

Syntax

```
void avl::SerialPort_ReadChar
(
 SerialPortState& ioState,
 int inPortId,
 atl::Conditional<atl::String>& outCharacter,
 bool& outOverflowOccurred
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	outCharacter	Conditional<String>&			Conditionally returns string with one received character.
	outOverflowOccurred	bool&			True when the internal read buffer reached its maximum size and oldest data was dropped since the last call.

Description

Filter reads single byte from input buffer and return data as a single character.

Filter perform non-blocking reading form buffer and will return NIL when no data was read.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_ReadChar filter.

Filter SerialPort_Config does not guarantee that input buffer will be empty.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters reading from serial port without previous configuration will cause "SerialPort not initialized" error.

See Also

- SerialPort_ReadBuffer – Reads raw binary data from serial port.
- SerialPort_ReadString – Reads string characters from serial port.
- SerialPort_ReadStringUntil – Reads the string from the serial port to encounter a string delimiter.

SerialPort_ReadString

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads string characters from serial port.

Syntax

```
void avl::SerialPort_ReadString
(
 SerialPortState& ioState,
 int inPortId,
 atl::Conditional<atl::String>& outString,
 bool& outOverflowOccurred
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SerialPortState&			Object used to maintain state of the function.
→	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
←	outString	Conditional<String>&			Conditionally returns string with concatenated all characters available in input buffer.
←	outOverflowOccurred	bool&			True when the internal read buffer reached its maximum size and oldest data was dropped since the last call.

Description

Filter reads all data from input and returns it as string. Result string will be read in UTF8 format.

Filter perform non-blocking reading form buffer and will return NIL when no data was read.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_ReadString filter.

Filter SerialPort_Config does not guarantee that input buffer will be empty.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters reading from serial port without previous configuration will cause "SerialPort not initialized" error.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_ReadByte – Reads one character in binary mode from serial port.
- SerialPort_ReadBuffer – Reads raw binary data from serial port.
- SerialPort_ReadChar – Reads single character from serial port.
- SerialPort_ReadStringUntil – Reads the string from the serial port to encounter a string delimiter.

SerialPort_ReadStringUntil

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads the string from the serial port to encounter a string delimiter.

Syntax

```
void avl::SerialPort_ReadStringUntil
(
 SerialPortState& ioState,
 int inPortId,
 const atl::String& inEndString,
 atl::Conditional<atl::String>& outString,
 bool& outOverflowOccurred
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	SerialPortState&			Object used to maintain state of the function.
→	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
→	inEndString	const String&			Delimiter string that will be searched in incoming stream.
←	outString	Conditional<String>&			Conditionally returns received string without delimiter.
←	outOverflowOccurred	bool&			True when the internal read buffer reached its maximum size and oldest data was dropped since the last call.

Description

Filter reads characters from input buffer until find **inEndString** delimiter is found. Returns data without delimiter.

Result string will be read in UTF8 format.

Delimiter provided in **inEndString** must contains only ASCII characters.

Filter perform non-blocking reading form buffer and will return NIL when no data was read.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_ReadStringUntil filter.

Filter SerialPort_Config does not guarantee that input buffer will be empty.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters reading from serial port without previous configuration will cause "SerialPort not initialized" error.

List of possible exceptions:

Error type	Description
	inEndString must contains only ASCII characters.
DomainError	Termination string must contain only ASCII characters.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_ReadByte – Reads one character in binary mode from serial port.
- SerialPort_ReadBuffer – Reads raw binary data from serial port.
- SerialPort_ReadChar – Reads single character from serial port.
- SerialPort_ReadString – Reads string characters from serial port.

Also in AVL Lite

SerialPort_WriteBuffer

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes raw binary data from a byte buffer to serial port.

Syntax

```
void avl::SerialPort_WriteBuffer
(
 SerialPortState& ioState,
 int inPortId,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	inBuffer	const ByteBuffer&			Buffer containing raw data to write

Examples

Filter writes raw data block from the **inBuffer** input to the serial port transmission output buffer.

Data buffer for the **inBuffer** input can be prepared using filters from the Binary Data category.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_WriteBuffer filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters writing to serial port without previous configuration will cause "SerialPort not initialized" error.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_WriteByte – Writes one character in binary mode to serial port.
- SerialPort_WriteString – Writes string characters to serial port.
- SerialPort_WriteChar – Writes single ASCII character to device.

Also in AVL Lite

SerialPort_WriteByte

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes one character in binary mode to serial port.

Syntax

```
void avl::SerialPort_WriteByte
(
 SerialPortState& ioState,
 int inPortId,
 int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	inData	int	0 – 255		Character value.

Description

Filters write single byte into output buffer.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_WriteByte filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters writing to serial port without previous configuration will cause "SerialPort not initialized" error.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_WriteBuffer – Writes raw binary data from a byte buffer to serial port.
- SerialPort_WriteString – Writes string characters to serial port.
- SerialPort_WriteChar – Writes single ASCII character to device.
- SerialPort_WriteByte – Writes one character in binary mode to serial port.

SerialPort_WriteChar

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes single ASCII character to device.

Syntax

```
void avl::SerialPort_WriteChar
(
 SerialPortState& ioState,
 int inPortId,
 const atl::String& inCharacter
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 – 7	0	Identifies open port instance when working with multiple serial ports
	inCharacter	const String&			Single character to send

Description

Filter writes single character **inCharacter** into input buffer. Input **inCharacter** must contains only single valid ASCII character.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_WriteChar filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters writing to serial port without previous configuration will cause "SerialPort not initialized" error.

List of possible exceptions:

Error type	Description
DomainError	Length inCharacter is greater than 1 in SerialPort_WriteChar.
DomainError	SerialPort_WriteChar can send only ASCII characters.
DomainError	Value inCharacter is empty in SerialPort_WriteChar.

See Also

- SerialPort_Config – Configures the serial port.
- SerialPort_WriteBuffer – Writes raw binary data from a byte buffer to serial port.
- SerialPort_WriteString – Writes string characters to serial port.
- SerialPort_WriteChar – Writes single ASCII character to device.
- SerialPort_WriteByte – Writes one character in binary mode to serial port.

SerialPort_WriteString

Header: STD.h
Namespace: avl
Module: FoundationLite

Writes string characters to serial port.

Syntax

```
void avl::SerialPort_WriteString
(
 SerialPortState& ioState,
 int inPortId,
 const atl::String& inString,
 bool inASCIIMode,
 const atl::Array<int>& inTerminator
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SerialPortState&			Object used to maintain state of the function.
	inPortId	int	0 - 7	0	Identifies open port instance when working with multiple serial ports
	inString	const String&			
	inASCIIMode	bool			
	inTerminator	const Array<int>&			

Examples

Filter writes **inString** characters to output buffer. By default string is send using UTF8 encoding (multi-byte).

When **inASCIIMode** is enabled filter will send only ASCII characters. Any attempt of sending non-ASCII character will result in domain error.

Remarks

Using the SerialPort_Config filter is necessary before using the SerialPort_WriteString filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

Using filters writing to serial port without previous configuration will cause "SerialPort not initialized" error.

List of possible exceptions:

Error type	Description
	SerialPort_WriteString can send only ASCII characters when inASCIIMode is selected.
DomainError	When option inASCIIMode is enabled, filter can send only an ASCII characters. Please check ASCII table codes for more informations.

See Also

- SerialPort_Config – Configures the serial port.

- TcpIp_ReadBuffer
- TcpIp_ReadLine
- TcpIp_WriteBuffer
- TcpIp_WriteText

TcpIp_Accept

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Accepts a connection from a remote client.

Syntax

```
void avl::TcpIp_Accept
(
 TcpIpAcceptState& ioState,
 int inPort,
 const atl::Optional<int>& inTimeout,
 const atl::Optional<int>& inKeepAliveTime,
 bool inNoSendDelay,
 atl::Conditional<avl::SocketId>& outSocket
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	TcpIpAcceptState&			Object used to maintain state of the function.
→	inPort	int	7 – 65535	12345	TCP port to listen on.
→	inTimeout	const Optional<int>&	0 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inKeepAliveTime	const Optional<int>&	2000 – ∞	NIL	When specified activates Tcp/Ip keep alive on new socket with given idle time.
→	inNoSendDelay	bool		False	Disables the Nagle algorithm for the newly connected socket to send the outgoing packets without a delay.
←	outSocket	Conditional<SocketId>&			Connected socket ID.

Description

This filter opens a server socket for listening for and accepting incoming connections, which stays open during the execution of the program.

For every execution this filter will wait for connection from a single client, accept this connection and return a new socket representing connection with the client. The **inTimeout** input specifies the longest possible waiting time, in milliseconds. When no timeout is specified (set to Auto), the execution is blocking. When filter execution is terminated by timeout condition no socket is returned (Nil is returned on **outSocket** output) and the operation can be retried later. When timeout is set to zero the filter performs a single check for incoming connection and returns immediately when no connecting clients are available.

Every socket created and returned by this filter must be explicitly closed with TcpIp_Close filter when it is not needed any more.

inKeepAliveTime can be used to enable Keep-Alive mechanism on newly established connection with the client.

Keep-Alive is a mechanism built in the TCP/IP stack, that can be helpful with detecting broken connection in systems with long communication idle periods or with communication in one direction only. When enabled, operating system will send additional control packets to check state of the connection. **inKeepAliveTime** input specifies the time, in milliseconds, of connection idle state after which connection state will be checked. The exact time after which connection broken state will be detected is system dependent.

The Aurora Vision Studio or Aurora Vision Executor process have to have the necessary permissions in local firewall to open a listening port on the executing host. The port is not bound to any specific networking interface or IP address. The port must not be listened to in another process.

This filter can raise IoError when specified port is already in use in local system, or when other unexpected network-related error occurs.

Hints

- Set **inPort** to the same port number that the other side of communication will attempt to connect to.
- Set **inTimeout** if you want the filter to abort waiting for a connection after a predefined time.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_Connect – Connects as a client to a remote TCP server socket.
- TcpIp_Close – Closes a connected TCP socket gracefully.

TcpIp_Close

Header: STD.h
Namespace: avl
Module: FoundationLite

Closes a connected TCP socket gracefully.

Syntax

```
void avl::TcpIp_Close
(
 avl::SocketId inSocket
)
```

Parameters

	Name	Type	Default	Description
➡	inSocket	SocketId		Connected socket Id.

Description

Closes the TCP/IP socket with underlying connection and releases resources owned by the socket.

All sockets, created with TcpIp_Connect and TcpIp_Accept should be closed with this filter after their use, regardless of the state of the connection and regardless of the fact whether the connection was closed by the other side.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_Accept – Accepts a connection from a remote client.
- TcpIp_Connect – Connects as a client to a remote TCP server socket.

TcpIp_Connect

Header: STD.h
Namespace: avl
Module: FoundationLite

Connects as a client to a remote TCP server socket.

Syntax

```
void avl::TcpIp_Connect
(
 TcpIpConnectState& ioState,
 const atl::String& inHost,
 int inPort,
 const atl::Optional<int>& inTimeout,
 const atl::Optional<int>& inKeepAliveTime,
 bool inNoSendDelay,
 atl::Conditional<avl::SocketId>& outSocket
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	TcpIpConnectState&			Object used to maintain state of the function.
→	inHost	const String&		\"localhost\"	The hostname or IP address to connect to.
→	inPort	int	7 – 65535	12345	TCP port of host to connect to.
→	inTimeout	const Optional<int>&	500 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inKeepAliveTime	const Optional<int>&	2000 – ∞	NIL	When specified activates Tcp/Ip keep alive on new socket with given idle time.
→	inNoSendDelay	bool		False	Disables the Nagle algorithm for the socket to send the outgoing packets without a delay.
←	outSocket	Conditional<SocketId>&			Connected socket ID.

Description

This filter connects to a listening TCP/IP socket.

The **inTimeout** input specifies the longest possible waiting time, in milliseconds, for the connection to be accepted. When no timeout is specified (set to Auto), the execution is blocking. When filter execution is terminated by timeout condition no socket is returned (Nil is returned on **outSocket** output) and the operation can be retried later. When remote host can not be found or when remote host is not listening on specified port the connection attempt is repeated until timeout expires. This filter can block for significantly longer than the timeout specified because its work is not cancelled in the middle of a single connection attempt.

Every socket created and returned by this filter must be explicitly closed with TcpIp_Close filter when it is not needed any more.

inKeepAliveTime can be used to enable Keep-Alive mechanism on newly established connection with the host.

Keep-Alive is a mechanism built in the TCP/IP stack, that can be helpful with detecting broken connection in systems with long communication idle periods or with communication in one direction only. When enabled, operating system will send additional control packets to check state of the connection. **inKeepAliveTime** input specifies the time, in milliseconds, of connection idle state after which connection state will be checked. The exact time after which connection broken state will be detected is system dependent.

The **inHost** parameter can be entered as a DNS host name or IP address. The time necessary to connect can vary, for example subsequent connections to the same host may be faster because of cached DNS information.

In case of failure for reasons other than timeout, IoError is raised.

Hints

- Set **inHost** to an IP address or an url of the server you want to connect to.
- Set **inPort** to the same port number that the other side of communication will be listening on.
- Set **inTimeout** if you want the filter to abort trying to connect after a predefined time.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_Accept – Accepts a connection from a remote client.
- TcpIp_Close – Closes a connected TCP socket gracefully.

TcpIp_ReadAllBuffer

Header: STD.h
Namespace: avl
Module: FoundationLite

Receives data from a connected socket until the other side closes connection.

Syntax

```
void avl::TcpIp_ReadAllBuffer
(
 avl::SocketId inSocket,
 const atl::Optional<int>& inTimeout,
 atl::Conditional<avl::ByteBuffer>& outBuffer,
 bool& outEof
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	SocketId			Connected socket ID, will be closed if successfully read.
→	inTimeout	const Optional<int>&	0 – ∞	NIL	Timeout in milliseconds, block if not specified.
←	outBuffer	Conditional<ByteBuffer>&			Buffer with raw received data, or Nil if the operation was interrupted by timeout.
←	outEof	bool&			Indicates whether the operation successfully read data to the end of stream.

Description

Reads all data until the other side stops sending and closes the connection on its side.

The **inTimeout** input specifies the longest possible waiting time, in milliseconds, for the incoming data to be fully received. When no timeout is specified (set to Auto), the execution is blocking. When the filter execution is terminated by timeout condition no data is returned or removed from the input buffer (Nil is returned instead). In such situation the operation can be retried later. When timeout is et to zero the filter performs a single read attempt and returns immediately when no data is available.

outBuffer is a buffer containing raw binary data (a sequence of bytes). Data buffer can be processed using filters from the Binary Data category.

outEof output is set to True when data was successfully received and the connection is closed by the other side. This output can be used as a more convenient way to detect end of communication in the application.

This filter can raise IoError when the connection is disruptively broken or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Set **inTimeout** if you want the filter to abort waiting for data after a predefined time.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_WriteBuffer – Outputs a block of raw data through a connected TCP socket.
- TcpIp_WriteText – Outputs a string through a connected TCP socket.
- TcpIp_ReadLine – Reads from a connected TCP socket until receiving a specific sequence.
- TcpIp_Close – Closes a connected TCP socket gracefully.

TcpIp_ReadAllText

Header: STD.h
Namespace: avl
Module: FoundationLite

Receives text from a connected socket until the other side closes connection.

Syntax

```
void avl::TcpIp_ReadAllText
(
 avl::SocketId inSocket,
 const atl::Optional<int>& inTimeout,
 atl::Conditional<atl::String>& outText,
 bool& outEof
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	SocketId			Connected socket ID, will be closed if successfully read.
→	inTimeout	const Optional<int>&	0 – ∞	NIL	Timeout in milliseconds, block if not specified.
←	outText	Conditional<String>&			Received data as textual string, or Nil if the operation was interrupted by timeout.
←	outEof	bool&			Indicates whether the operation successfully read data to the end of stream.

Description

Reads all data until the other side stops sending and closes the connection on its side.

The **inTimeout** input specifies the longest possible waiting time, in milliseconds, for the incoming data to be fully received. When no timeout is specified (set to Auto), the execution is blocking. When the filter execution is terminated by timeout condition no data is returned or removed from the input buffer (Nil is returned instead). In such situation the operation can be retried later. When timeout is et to zero the filter performs a single read attempt and returns immediately when no data is available.

Received bytes are interpreted as UTF-8 encoded text and returned on **outText** output. When received data is not in a valid UTF-8 encoding an IOError is raised.

outEof output is set to True when data was successfully received and the connection is closed by the other side. This output can be used as a more convenient way to detect end of communication in the application.

This filter can raise IoError when the connection is disruptively broken or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Set **inTimeout** if you want the filter to abort waiting for data after a predefined time.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_WriteBuffer – Outputs a block of raw data through a connected TCP socket.
- TcpIp_WriteText – Outputs a string through a connected TCP socket.
- TcpIp_ReadLine – Reads from a connected TCP socket until receiving a specific sequence.
- TcpIp_Close – Closes a connected TCP socket gracefully.

TcpIp_ReadBuffer

Header: STD.h
Namespace: avl
Module: FoundationLite

Receives a fixed number of bytes from a connected TCP socket.

Syntax

```
void avl::TcpIp_ReadBuffer
(
 avl::SocketId inSocket,
 int inLength,
 const atl::Optional<int>& inTimeout,
 bool inAcceptEof,
 atl::Conditional<avl::ByteBuffer>& outBuffer,
 bool& outEof
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	SocketId			Connected socket ID.
→	inLength	int	1 – 20971520		Number of bytes to receive.
→	inTimeout	const Optional<int>&	0 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inAcceptEof	bool		False	When false, throws an IoError on attempt to read data from beyond the end of stream; when true interrupts operation without exception in such a case.
←	outBuffer	Conditional<ByteBuffer>&			Buffer with raw received data, or Nil if the operation was interrupted (by timeout or reading beyond the end of stream).
←	outEof	bool&			Indicates whether the operation was interrupted on attempt to get data from beyond the end of stream.

Description

This filter reads a fixed number of bytes from the socket. The number of bytes is specified by the **inLength** input.

The **inTimeout** input specifies the longest possible waiting time, in milliseconds, for the incoming data to be fully received. When no timeout is specified (set to Auto), the execution is blocking. When the filter execution is terminated by timeout condition no data is returned or removed from the input buffer (Nil is returned instead). In such situation the operation can be retried later. When timeout is et to zero the filter performs a single read attempt and returns immediately when no data is available.

outBuffer is a buffer containing raw binary data (a sequence of bytes). Data buffer can be processed using filters from the Binary Data category.

The **outEof** output can be used to detect whether the peer finished transmission and gracefully closed connection on its side. To enable this **inAcceptEof** must be set, otherwise connection closing will be treated as erroneous state.

The point in transmission when the other side closes the connection gracefully is known as the end of stream (or End of File – Eof). All TCP/IP reading filters can normally read data remaining in the input buffer even when the connection has been closed, as long as the whole required chunk of data is present in the input buffer. However, the reaction to the attempt to read from the input buffer beyond the end of the stream depends on the **inAcceptEof** input. When **inAcceptEof** is set to False the filter will raise IO_Error when required chunk of data cannot be read. When **inAcceptEof** is set to True the filter execution is terminated, no data is removed from the input buffer, Nil is returned instead of requested data and the **outEof** output is set to True. In such situation the socket remains valid and subsequent reads will perform similar data read attempts.

This filter can raise IO_Error when the connection is disruptively broken or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Set **inLength** to the number of bytes you want to read.
- Set **inTimeout** if you want the filter to abort waiting for data after a predefined time.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_WriteBuffer – Outputs a block of raw data through a connected TCP socket.
- TcpIp_ReadLine – Reads from a connected TCP socket until receiving a specific sequence.
- TcpIp_ReadAllBuffer – Receives data from a connected socket until the other side closes connection.

Header: STD.h
Namespace: avl
Module: FoundationLite

Reads from a connected TCP socket until receiving a specific sequence.

Syntax

```
void avl::TcpIp_ReadLine
(
 avl::SocketId inSocket,
 const atl::String& inDelimiter,
 const atl::Optional<int>& inTimeout,
 bool inAcceptEof,
 avl::DelimiterHandling::Type inMode,
 atl::Conditional<atl::String>& outText,
 bool& outEof
)
```

Parameters

	Name	Type	Range	Default	Description
→	inSocket	SocketId			Connected socket ID.
→	inDelimiter	const String&		\"\\\\r\\\\n\"	Terminating character sequence, escaped.
→	inTimeout	const Optional<int>&	0 – ∞	NIL	Timeout in milliseconds, block if not specified.
→	inAcceptEof	bool		False	When false, throws an IoError on attempt to read data from beyond the end of stream; when true interrupts operation without exception in such a case.
→	inMode	DelimiterHandling::Type			Delimiter handling mode.
←	outText	Conditional<String>&			Received data as textual string, or Nil if the operation was interrupted (by timeout or reading beyond the end of stream).
←	outEof	bool&			Indicates whether the operation was interrupted on attempt to get data from beyond the end of stream.

Description

This filter can read a sequence of characters of variable length from an open socket. The characters are terminated by a sequence, which is specified via **inDelimiter**.

The value on the **inDelimiter** input can contain escape sequences.

An escaped string contains *escape sequences*, which are combinations of the \ (backslash) and another character, which have special meaning. The supported escape sequences are:

- \r – carriage return (ASCII 13)
- \n – new line (ASCII 10)
- \t – tab character (ASCII 9)
- \\ – verbatim backslash \

The **inTimeout** input specifies the longest possible waiting time, in milliseconds, for the incoming data to be fully received. When no timeout is specified (set to Auto), the execution is blocking. When the filter execution is terminated by timeout condition no data is returned or removed from the input buffer (Nil is returned instead). In such situation the operation can be retried later. When timeout is et to zero the filter performs a single read attempt and returns immediately when no data is available.

Received bytes are interpreted as UTF-8 encoded text and returned on **outText** output. When received data is not in a valid UTF-8 encoding IoError is raised.

The **outEof** output can be used to detect whether the peer finished transmission and gracefully closed connection on its side. To enable this **inAcceptEof** must be set, otherwise connection closing will be treated as erroneous state.

The point in transmission when the other side closes the connection gracefully is known as the end of stream (or End of File – Eof). All TCP/IP reading filters can normally read data remaining in the input buffer even when the connection has been closed, as long as the whole required chunk of data is present in the input buffer. However, the reaction to the attempt to read from the input buffer beyond the end of the stream depends on the **inAcceptEof** input. When **inAcceptEof** is set to False the filter will raise IO_Error when required chunk of data cannot be read. When **inAcceptEof** is set to True the filter execution is terminated, no data is removed from the input buffer, Nil is returned instead of requested data and the **outEof** output is set to True. In such situation the socket remains valid and subsequent reads will perform similar data read attempts.

This filter can raise IoError when the connection is disruptively broken or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Set **inDelimiter** to define a character sequence that defines end of line. "\r\n" is the typical value of end of line for Windows-based systems.
- Set **inTimeout** if you want the filter to abort waiting for data after a predefined time.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty delimiter in TcpIp_ReadLine

See Also

- TcpIp_WriteText – Outputs a string through a connected TCP socket.
- TcpIp_ReadBuffer – Receives a fixed number of bytes from a connected TCP socket.
- TcpIp_ReadAllText – Receives text from a connected socket until the other side closes connection.

TcpIp_WriteBuffer

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Outputs a block of raw data through a connected TCP socket.

Syntax

```
void avl::TcpIp_WriteBuffer
(
 avl::SocketId inSocket,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Default	Description
→	inSocket	SocketId		Connected socket ID.
→	inBuffer	const ByteBuffer&		Buffer with data to send.

Description

This filter writes arbitrary bytes to a connected socket.

Data buffer for the **inBuffer** input can be prepared using filters from the Binary Data category.

This filter can raise IoError when the connection is broken or closed by the other side, when the output buffer overflows because the other side is not receiving data or receiving data too slow, or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Connect the data you want to send to the **inBuffer** input.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_ReadLine – Reads from a connected TCP socket until receiving a specific sequence.
- TcpIp_ReadBuffer – Receives a fixed number of bytes from a connected TCP socket.
- TcpIp_WriteText – Outputs a string through a connected TCP socket.

TcpIp_WriteText

Also in AVL Lite

Header: STD.h
Namespace: avl
Module: FoundationLite

Outputs a string through a connected TCP socket.

Syntax

```
void avl::TcpIp_WriteText
(
 avl::SocketId inSocket,
 const atl::String& inText,
 const atl::String& inSuffix
)
```

Parameters

	Name	Type	Default	Description
➡	inSocket	SocketId		Connected socket ID.
➡	inText	const String&		Text to send through socket.
➡	inSuffix	const String&	\"\\\\r\\\\n\"	Additional data to send, like a newline, escaped.

Description

This filter writes textual data to a connected socket.

The text from **inText** is sent through the connected socket, and if the **inSuffix** is given, it is sent after. Either parameter can be the empty string, but when both are empty, no data is sent through the socket. The text is sent using UTF-8 encoding.

The value on the **inSuffix** input can contain escape sequences.

An escaped string contains *escape sequences*, which are combinations of the \ (backslash) and another character, which have special meaning. The supported escape sequences are:

- \r - carriage return (ASCII 13)
- \n - new line (ASCII 10)
- \t - tab character (ASCII 9)
- \\ - verbatim backslash \

This filter can raise IoError when the connection is broken or closed by the other side, when the output buffer overflows because the other side is not receiving data or receiving data too slow, or when other network-related error occurred.

Hints

- Connect **inSocket** with the output of TcpIp_Connect or TcpIp_Accept.
- Connect the data you want to send to the **inText** input.
- Additional suffix defined on **inSuffix** will be added at the end of sent chunk.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- TcpIp_ReadLine - Reads from a connected TCP socket until receiving a specific sequence.
- TcpIp_ReadBuffer - Receives a fixed number of bytes from a connected TCP socket.

AdamTCP_Connect

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Connects as a client to a remote Advantech Adam device.

Syntax

```
void avl::AdamTCP_Connect
(
 AdamTCP_State& ioState,
 const atl::String& inDeviceIP,
 const atl::Optional<int>& inTimeout,
 const atl::Optional<int>& inKeepAliveTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdamTCP_State&			Object used to maintain state of the function.
	inDeviceIP	const String&			The Advantech Adam device IP address to connect to.
	inTimeout	const Optional<int>&	500 – ∞	NIL	Timeout in milliseconds, block if not specified.
	inKeepAliveTime	const Optional<int>&	2000 – ∞	NIL	When specified activates Tcp/Ip keep alive on new socket with given idle time.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AdamTCP_Function01

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Function code 01. Reads discrete output's ON/OFF status.

Syntax

```
void avl::AdamTCP_Function01
(
 AdamTCP_State& ioState,
 const atl::Optional<atl::String>& inDeviceIP,
 int inStationAddress,
 int inStartAddress,
 int inNumberOfCoils,
 atl::Array<int>& outValues,
 atl::Array<bool>& outStatuses
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdamTCP_State&			Object used to maintain state of the function.
→	inDeviceIP	const Optional<String>&		NIL	The Advantech Adam device IP address.
→	inStationAddress	int	0 – ∞	1	
→	inStartAddress	int			The address of the first coil.
→	inNumberOfCoils	int	1 – 2000		Requested number of bits.
←	outValues	Array<int>&			Received values as integers.
←	outStatuses	Array<bool>&			Received statuses as bits.

Remarks

You need to specify the IP address of your Adam device in the **inDeviceIP** port only in the first filter which is using the device. In the consecutive filters you can leave **inDeviceIP** set to Auto, these filters will connect to the device with the IP address specified in the first filter.

For a more detailed description of the function from this article and other Adam functions available in Aurora Vision, please refer to the Advantech documentation for your device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- AdamTCP_Function02 – Function code 02. Reads discrete input's ON/OFF status.
- AdamTCP_Function03 – Function code 03. Reads the binary contents of input registers.
- AdamTCP_Function04 – Function code 04. Reads the binary contents of input registers.
- AdamTCP_Function05 – Function code 05. Forces a single coil to either ON or OFF.

AdamTCP_Function02

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Function code 02. Reads discrete input's ON/OFF status.

Syntax

```
void avl::AdamTCP_Function02
(
 AdamTCP_State& ioState,
 const atl::Optional<atl::String>& inDeviceIP,
 int inStationAddress,
 int inStartAddress,
 int inNumberOfCoils,
 atl::Array<int>& outValues,
 atl::Array<bool>& outStatuses
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdamTCP_State&			Object used to maintain state of the function.
→	inDeviceIP	const Optional<String>&		NIL	The Advantech Adam device IP address.
→	inStationAddress	int	0 – ∞	1	
→	inStartAddress	int			The address of the first input.
→	inNumberOfCoils	int	1 – ∞		Requested number of bits.
←	outValues	Array<int>&			Received values as integers.
←	outStatuses	Array<bool>&			Received statuses as bits.

Remarks

You need to specify the IP address of your Adam device in the **inDeviceIP** port only in the first filter which is using the device. In the consecutive filters you can leave **inDeviceIP** set to Auto, these filters will connect to the device with the IP address specified in the first filter.

For a more detailed description of the function from this article and other Adam functions available in Aurora Vision, please refer to the Advantech documentation for your device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- AdamTCP_Function01 – Function code 01. Reads discrete output's ON/OFF status.
- AdamTCP_Function03 – Function code 03. Reads the binary contents of input registers.
- AdamTCP_Function04 – Function code 04. Reads the binary contents of input registers.
- AdamTCP_Function05 – Function code 05. Forces a single coil to either ON or OFF.

AdamTCP_Function03

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Function code 03. Reads the binary contents of input registers.

Syntax

```
void avl::AdamTCP_Function03
(
 AdamTCP_State& ioState,
 const atl::Optional<atl::String>& inDeviceIP,
 int inStationAddress,
 int inStartAddress,
 int inNumberOfRegister,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdamTCP_State&			Object used to maintain state of the function.
→	inDeviceIP	const Optional<String>&		NIL	The Advantech Adam device IP address.
→	inStationAddress	int	0 – ∞	1	
→	inStartAddress	int			The address of the first holding register.
→	inNumberOfRegister	int	1 – ∞		Number of registers to read.
←	outValues	Array<int>&			Received values as integers.

Remarks

You need to specify the IP address of your Adam device in the **inDeviceIP** port only in the first filter which is using the device. In the consecutive filters you can leave **inDeviceIP** set to Auto, these filters will connect to the device with the IP address specified in the first filter.

For a more detailed description of the function from this article and other Adam functions available in Aurora Vision, please refer to the Advantech documentation for your device.

AdamTCP_Function04

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Function code 04. Reads the binary contents of input registers.

Syntax

```
void avl::AdamTCP_Function04
(
 AdamTCP_State& ioState,
 const atl::Optional<atl::String>& inDeviceIP,
 int inStationAddress,
 int inStartAddress,
 int inNumberOfRegister,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdamTCP_State&			Object used to maintain state of the function.
	inDeviceIP	const Optional<String>&		NIL	The Advantech Adam device IP address.
	inStationAddress	int	0 – ∞	1	
	inStartAddress	int			The address of the first input register.
	inNumberOfRegister	int	1 – ∞		Number of registers to read.
	outValues	Array<int>&			Received values as integers.

Remarks

AdamTCP_Function05

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Function code 05. Forces a single coil to either ON or OFF.

Syntax

```
void avl::AdamTCP_Function05
(
 AdamTCP_State& ioState,
 const atl::Optional<atl::String>& inDeviceIP,
 int inStationAddress,
 int inCoilAddress,
 bool inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdamTCP_State&			Object used to maintain state of the function.
	inDeviceIP	const Optional<String>&		NIL	The Advantech Adam device IP address.
	inStationAddress	int	0 – ∞	1	
	inCoilAddress	int	0 – ∞	16	The address of the coil to be forced.
	inState	bool			Coil state to be set.

Remarks

You need to specify the IP address of your Adam device in the **inDeviceIP** port only in the first filter which is using the device. In the consecutive filters you can leave **inDeviceIP** set to Auto, these filters will connect to the device with the IP address specified in the first filter.

DAQNavi_GetDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns value from digital input.

Syntax

```
void avl::DAQNavi_GetDigitalInput
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 int& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQNavi_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Description or index of device
	inPort	int	0 – + ∞		Port number
	outValue	int&			Output value

Remarks

Board driver software

This filter is intended to cooperate with digital I/O cards using its vendor SDK. To be able to connect to a card it is required to install DAQNavi SDK software. Currently Aurora Vision Studio requires **DAQNavi SDK version 4.1.3**.

DAQNavi SDK can be downloaded from the following website: https://www.advantech.com.

Device identification

When there is only one device connected to computer, **inDeviceID** field can be set to Auto. In this situation first available device will be found and connected.

inDeviceID can be used to pick one of multiple devices connected to computer. Set this field to Device Description (for example "DemoDevice, BID#000"), or to Device Number(for example "0"). Both parameters should be available in Advantech Navigator.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- DAQNavi_SetPortDirection – Sets the port direction (input or output).
- DAQNavi_GetDigitalInputs – Returns values from all digital inputs.
- DAQNavi_InitInterrupts – Initializes interrupts.
- DAQNavi_GetDigitalInterrupt – Returns interrupt values.
- DAQNavi_SetDigitalOutput – Sets digital output value.

DAQNavi_GetDigitalInputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns values from all digital inputs.

Syntax

```
void avl::DAQNavi_GetDigitalInputs
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQNavi_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Description or index of device
	outValues	Array<int>&		Output values

Remarks

DAQNavi_GetDigitalInterrupt

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns interrupt values.

Syntax

```
void avl::DAQNavi_GetDigitalInterrupt
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inSrcChannel,
 int inPort,
 atl::Array<int>& outPortValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	DAQNavi_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Description or index of device
→	inSrcChannel	int	0 – +∞		Channel number which snap event occurs
→	inPort	int	0 – +∞		Port number to scan when interrupt occurred
←	outPortValues	Array<int>&			Port values scanned when interrupt occurred

Remarks

DAQNavi_GetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets digital output value.

Syntax

```
void avl::DAQNavi_GetDigitalOutput
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 int& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	DAQNavi_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Description or index of device
→	inPort	int	0 – +∞		Port used for outputting data
←	outValue	int&			Value to output

DAQNavi_GetDigitalOutputBit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets digital output bit value.

Syntax

```
void avl::DAQNavi_GetDigitalOutputBit
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 int inBitId,
 bool& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	DAQNavi_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Description or index of device
→	inPort	int	0 – +∞		Port used for outputting data
→	inBitId	int	0 – 8		Bit id within the selected port
←	outValue	bool&			Value to output

DAQNavi_InitInterrupts

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes interrupts.

Syntax

```
void avl::DAQNavi_InitInterrupts
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::Array<int>& inChannels,
 avl::DAQNaviTrigger::Type inTriggerMode
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQNavi_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Description or index of device
	inChannels	const Array<int>&		Interrupted channel numbers
	inTriggerMode	DAQNaviTrigger::Type		Trigger mode

DAQNavi_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital output value.

Syntax

```
void avl::DAQNavi_SetDigitalOutput
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 int inValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQNavi_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Description or index of device
	inPort	int	0 – +∞		Port used for outputting data
	inValue	int	0 – 255		Value to output

DAQNavi_SetDigitalOutputBit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital output bit to specified value.

Syntax

```
void avl::DAQNavi_SetDigitalOutputBit
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 int inBitId,
 bool inValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQNavi_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Description or index of device
	inPort	int	0 – +∞		Port used for outputting data
	inBitId	int	0 – 8		Bit id within the selected port
	inValue	bool			Value to output

DAQNavi_SetPortDirection

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the port direction (input or output).

Syntax

```
void avl::DAQNavi_SetPortDirection
(
 DAQNavi_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inPort,
 bool inPortIsOutput
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQNavi_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Description or index of device
	inPort	int	0 – +∞		Port number
	inPortIsOutput	bool			True if port should be an output, false if port should be an input

Remarks

AdvantechSUSI_GetFrequencyI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets frequency of I2C bus.

Syntax

```
void avl::AdvantechSUSI_GetFrequencyI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int& outFrequency
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inDevice	Optional<int>	1 - 6	NIL	Select I2C device or empty for main host device.
←	outFrequency	int&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_GetGPIOPortLevel_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO level.

Syntax

```
void avl::AdvantechSUSI_GetGPIOPortLevel_Multiple
(
 AdvantechSUSI_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 atl::Array<bool>& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inBank	int	0 – ∞		
→	inMask	Optional<const Array<bool>&>		NIL	
←	outLevel	Array<bool>&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_GetGPIOPortLevel_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO level.

Syntax

```
void avl::AdvantechSUSI_GetGPIOPortLevel_Single
(
 AdvantechSUSI_State& ioState,
 int inPort,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inPort	int	0 – ∞		
←	outLevel	bool&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

AdvantechSUSI_GetThermalProtection

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets thermal protection.

Syntax

```
void avl::AdvantechSUSI_GetThermalProtection
(
 AdvantechSUSI_State& ioState,
 int inProtectionZone,
 avl::AdvantechSUSIBoardTemperatureSensor::Type& outSource,
 avl::AdvantechSUSITemperatureEvent::Type& outEvent,
 float& outEventSend,
 float& outEventClear
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inProtectionZone	int	0 – 3		
←	outSource	AdvantechSUSIBoardTemperatureSensor::Type&			
←	outEvent	AdvantechSUSITemperatureEvent::Type&			
←	outEventSend	float&			Unit is Kelvins. When thermal source goes over this value, SUSI will send event according event.
←	outEventClear	float&			Unit is Kelvins. When thermal source goes below this value, SUSI will clear event according event.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

AdvantechSUSI_LockStorageArea

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Locks storage area.

Syntax

```
void avl::AdvantechSUSI_LockStorageArea
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inStorage,
 const avl::ByteBuffer& inKey
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inStorage	Optional<int>	1 – 11	NIL	Automatic value for standard device.
	inKey	const ByteBuffer&			Storage password.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadBlockSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads block from SMBus.

Syntax

```
void avl::AdvantechSUSI_ReadBlockSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int inReadSize,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
→	inAddress	int	0 – 255		
→	inCommand	int	0 – 255		
→	inReadSize	int	1 – ∞		
←	outBuffer	ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadBlockSMBI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads block from SMBus-I2C.

Syntax

```
void avl::AdvantechSUSI_ReadBlockSMBI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int inReadSize,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
→	inAddress	int	0 – 255		
→	inCommand	int	0 – 255		
→	inReadSize	int	1 – ∞		
←	outBuffer	ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadByteSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads byte from SMBus.

Syntax

```
void avl::AdvantechSUSI_ReadByteSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	outData	int&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads from I2C device.

Syntax

```
void avl::AdvantechSUSI_ReadI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 bool inLongAddressFormat,
 avl::AdvantechSUSII2CCommandType::Type inCommandType,
 int inCommand,
 int inReadSize,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inDevice	Optional<int>	1 – 6	NIL	Select I2C device or empty for main host device.
→	inAddress	int	0 – 1023		Device address as 7 or 10 bit number
→	inLongAddressFormat	bool			Activate 10 bit address format.
→	inCommandType	AdvantechSUSII2CCommandType::Type			
→	inCommand	int			
→	inReadSize	int	1 – ∞		
←	outBuffer	ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadQuickSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Turns SMBus device function off (on) or disable (enable) a specific device mode.

Syntax

```
void avl::AdvantechSUSI_ReadQuickSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadStorageArea

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads from storage area.

Syntax

```
void avl::AdvantechSUSI_ReadStorageArea
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inStorage,
 int inOffset,
 int inReadSize,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inStorage	Optional<int>	1 – 11	NIL	
→	inOffset	int	0 – ∞		
→	inReadSize	int	1 – ∞		
←	outBuffer	ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReadWordSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads word from SMBus.

Syntax

```
void avl::AdvantechSUSI_ReadWordSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	outData	int&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_ReceiveByteSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receive byte from SMBus.

Syntax

```
void avl::AdvantechSUSI_ReceiveByteSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	outData	int&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SendByteSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Send byte to SMBus.

Syntax

```
void avl::AdvantechSUSI_SendByteSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inData	int	0 – 255		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetFrequencyI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets frequency of I2C bus.

Syntax

```
void avl::AdvantechSUSI_SetFrequencyI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inFrequency
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 6	NIL	Select I2C device or empty for main host device.
	inFrequency	int			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetGPIOPortDirection_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets GPIO direction.

Syntax

```
void avl::AdvantechSUSI_SetGPIOPortDirection_Multiple
(
 AdvantechSUSI_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 atl::Array<avl::AdvantechSUSIPortDirection::Type> inDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inBank	int	0 – ∞		
	inMask	Optional<const Array<bool>&>		NIL	
	inDirection	Array<AdvantechSUSIPortDirection::Type>			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetGPIOPortDirection_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets GPIO direction.

Syntax

```
void avl::AdvantechSUSI_SetGPIOPortDirection_Single
(
 AdvantechSUSI_State& ioState,
 int inPort,
 avl::AdvantechSUSIPortDirection::Type inDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inPort	int	0 – ∞		
	inDirection	AdvantechSUSIPortDirection::Type			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetGPIOPortLevel_Multiple

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets GPIO level.

Syntax

```
void avl::AdvantechSUSI_SetGPIOPortLevel_Multiple
(
 AdvantechSUSI_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 const atl::Array<bool>& inLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inBank	int	0 – ∞		
	inMask	Optional<const Array<bool>&>		NIL	
	inLevel	const Array<bool>&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetGPIOPortLevel_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets GPIO level.

Syntax

```
void avl::AdvantechSUSI_SetGPIOPortLevel_Single
(
 AdvantechSUSI_State& ioState,
 int inPort,
 bool inLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inPort	int	0 – ∞		
	inLevel	bool			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_SetThermalProtection

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets thermal protection.

Syntax

```
void avl::AdvantechSUSI_SetThermalProtection
(
 AdvantechSUSI_State& ioState,
 int inProtectionZone,
 avl::AdvantechSUSIBoardTemperatureSensor::Type inSource,
 avl::AdvantechSUSITemperatureEvent::Type inEvent,
 float inEventSend,
 float inEventClear
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inProtectionZone	int	0 – 3		
	inSource	AdvantechSUSIBoardTemperatureSensor::Type			
	inEvent	AdvantechSUSITemperatureEvent::Type			
	inEventSend	float	1.0 – ∞	274.0f	Unit is Kelvins. When thermal source goes over this value, SUSI will send event according event.
	inEventClear	float	1.0 – ∞	274.0f	Unit is Kelvins. When thermal source goes below this value, SUSI will clear event according event.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_UnlockStorageArea

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Unlocks storage area.

Syntax

```
void avl::AdvantechSUSI_UnlockStorageArea
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inStorage,
 const avl::ByteBuffer& inKey
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inStorage	Optional<int>	1 – 11	NIL	Automatic value for standard device.
	inKey	const ByteBuffer&			Storage password

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WatchDogGetLimits

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets hardware watchdog configuration.

Syntax

```
void avl::AdvantechSUSI_WatchDogGetLimits
(
 AdvantechSUSI_State& ioState,
 int inWatchdogTimerId,
 avl::ValueLimits& outDelayTimeLimits,
 avl::ValueLimits& outEventTimeLimits,
 avl::ValueLimits& outResetTimeLimits,
 int& outMinimumUnit
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inWatchdogTimerId	int	1 – 3		
	outDelayTimeLimits	ValueLimits&			
	outEventTimeLimits	ValueLimits&			
	outResetTimeLimits	ValueLimits&			
	outMinimumUnit	int&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WatchDogStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts hardware watchdog timer..

Syntax

```
void avl::AdvantechSUSI_WatchDogStart
(
 AdvantechSUSI_State& ioState,
 int inWatchdogTimerId,
 int inDelayTime,
 int inEventTime,
 int inResetTime,
 avl::AdvantechSUSIWatchdogEvent::Type inEventType
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inWatchdogTimerId	int	1 – 3		
	inDelayTime	int	0 – ∞		Initial delay for the watchdog timer in milliseconds.
	inEventTime	int	0 – ∞		Watchdog timeout interval in milliseconds to trigger an event.
	inResetTime	int	0 – ∞		Watchdog timeout interval in milliseconds to trigger a reset.
	inEventType	AdvantechSUSIWatchdogEvent::Type			

Description

Please check minimum unit value with AdvantechSUSI_WatchDogGetLimits. Watchdog values lower than this value will not take effect.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WatchDogStop

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops hardware watchdog timer.

Syntax

```
void avl::AdvantechSUSI_WatchDogStop
(
 AdvantechSUSI_State& ioState,
 int inWatchdogTimerId
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inWatchdogTimerId	int	1 – 3		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WatchDogTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Triggers hardware watchdog timer.

Syntax

```
void avl::AdvantechSUSI_WatchDogTrigger
(
 AdvantechSUSI_State& ioState,
 int inWatchdogTimerId
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechSUSI_State&		Object used to maintain state of the function.
	inWatchdogTimerId	int		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteBlockSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes block to SMBus.

Syntax

```
void avl::AdvantechSUSI_WriteBlockSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	inBuffer	const ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteBlockSMBI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes block to SMBus-I2C.

Syntax

```
void avl::AdvantechSUSI_WriteBlockSMBI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	inBuffer	const ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteByteSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes byte to SMBus.

Syntax

```
void avl::AdvantechSUSI_WriteByteSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	inData	int	0 – 255		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes to I2C device.

Syntax

```
void avl::AdvantechSUSI_WriteI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 bool inLongAddressFormat,
 avl::AdvantechSUSII2CCommandType::Type inCommandType,
 int inCommand,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 6	NIL	Select I2C device or empty for main host device.
	inAddress	int	0 – 1023		Device address as 7 or 10 bit number
	inLongAddressFormat	bool			Activate 10 bit address format.
	inCommandType	AdvantechSUSII2CCommandType::Type			
	inCommand	int			
	inBuffer	const ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteQuickSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Turns SMBus device function off (on) or disable (enable) a specific device mode.

Syntax

```
void avl::AdvantechSUSI_WriteQuickSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteReadI2C

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads and writes to I2C bus.

Syntax

```
void avl::AdvantechSUSI_WriteReadI2C
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 const avl::ByteBuffer& inBuffer,
 int inReadSize,
 avl::ByteBuffer& outBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
→	inDevice	Optional<int>	1 – 6	NIL	Select I2C device or empty for main host device.
→	inAddress	int	0 – 127		Device address as 7 bit number.
→	inBuffer	const ByteBuffer&			Empty buffer mean no write operation
→	inReadSize	int	1 – ∞		Zero size mean no read operation
←	outBuffer	ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteStorageArea

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes to storage area.

Syntax

```
void avl::AdvantechSUSI_WriteStorageArea
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inStorage,
 int inOffset,
 const avl::ByteBuffer& inBuffer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inStorage	Optional<int>	1 – 11	NIL	Automatic value for standard device.
	inOffset	int	0 – ∞		
	inBuffer	const ByteBuffer&			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechSUSI_WriteWordSMB

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes word to SMBus.

Syntax

```
void avl::AdvantechSUSI_WriteWordSMB
(
 AdvantechSUSI_State& ioState,
 atl::Optional<int> inDevice,
 int inAddress,
 int inCommand,
 int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechSUSI_State&			Object used to maintain state of the function.
	inDevice	Optional<int>	1 – 4	NIL	Select SMBus device or empty for main host device.
	inAddress	int	0 – 255		
	inCommand	int	0 – 255		
	inData	int	0 – 65535		

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Advantech SUSI SDK.

Add DLL path to system environment variable is required.

Recommended runtime version for Aurora Vision Studio usage is **4**.

Setup low level system functionality e.g. watchdog may still affect the system after the program finished.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechUNO_GetBacklightBrightness

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the backlight brightness.

Syntax

```
void avl::AdvantechUNO_GetBacklightBrightness
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBacklight::Type& inBacklight,
 atl::int64& outBrightnessLevel
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	inBacklight	AdvantechUNOBacklight::Type&		Backlight ID.
	outBrightnessLevel	int64&		Brightness level.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- AdvantechUNO_GetBacklightLimits – Gets the display capabilities.

AdvantechUNO_GetBacklightLimits

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the display capabilities.

Syntax

```
void avl::AdvantechUNO_GetBacklightLimits
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBacklight::Type& inBacklight,
 atl::int64& outMinBrightness,
 atl::int64& outMaxBrightness,
 bool& outAutoBrightness
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	inBacklight	AdvantechUNOBacklight::Type&		Backlight ID.
	outMinBrightness	int64&		Minimum brightness level.
	outMaxBrightness	int64&		Maximum brightness level.
	outAutoBrightness	bool&		State of auto brightness.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechUNO_GetBoardParameter_Int

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a board parameter of type Int.

Syntax

```
void avl::AdvantechUNO_GetBoardParameter_Int
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBoardParameterInt::Type& inParameter,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
→	inParameter	AdvantechUNOBoardParameterInt::Type&		Parameter name.
←	outValue	int64&		Parameter value.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- AdvantechUNO_GetBoardParameter_String – Gets a board parameter of type String.

AdvantechUNO_GetBoardParameter_String

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a board parameter of type String.

Syntax

```
void avl::AdvantechUNO_GetBoardParameter_String
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBoardParameterString::Type& inParameter,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	inParameter	AdvantechUNOBoardParameterString::Type&		Parameter name.
	outValue	String&		Parameter value.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- AdvantechUNO_GetBoardParameter_Int – Gets a board parameter of type Int.

AdvantechUNO_GetGPIOMasks

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO masks.

Syntax

```
void avl::AdvantechUNO_GetGPIOMasks
(
 AdvantechUNO_State& ioState,
 int inBank,
 atl::Array<bool>& outInputMask,
 atl::Array<bool>& outOutputMask
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
→	inBank	int	0 – ∞	0	GPIO bank ID.
←	outInputMask	Array<bool>&			Supported GPIO input bit mask.
←	outOutputMask	Array<bool>&			Supported GPIO output bit mask.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

AdvantechUNO_GetGPIOPinDirection_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO directions.

Syntax

```
void avl::AdvantechUNO_GetGPIOPinDirection_Multiple
(
 AdvantechUNO_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 atl::Array<avl::AdvantechUNOPinDirection::Type>& outDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
	inBank	int	0 – ∞	0	GPIO bank.
	inMask	Optional<const Array<bool>&>		NIL	GPIO mask.
	outDirection	Array<AdvantechUNOPinDirection::Type>&			GPIO directions.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

AdvantechUNO_GetGPIOPinDirection_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO direction.

Syntax

```
void avl::AdvantechUNO_GetGPIOPinDirection_Single
(
 AdvantechUNO_State& ioState,
 int inPin,
 avl::AdvantechUNOPinDirection::Type& outDirection
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
→	inPin	int	0 – ∞	0	GPIO pin.
←	outDirection	AdvantechUNOPinDirection::Type&			GPIO direction.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

AdvantechUNO_GetGPIOPinLevel_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GPIO levels.

Syntax

```
void avl::AdvantechUNO_GetGPIOPinLevel_Multiple
(
 AdvantechUNO_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 atl::Array<bool>& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
→	inBank	int	0 – ∞	0	GPIO bank.
→	inMask	Optional<const Array<bool>&>		NIL	GPIO mask.
←	outLevel	Array<bool>&			GPIO levels.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

AdvantechUNO_GetLEDStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the LED status.

Syntax

```
void avl::AdvantechUNO_GetLEDStatus
(
 AdvantechUNO_State& ioState,
 int inLedId,
 int& outStatus
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
→	inLedId	int	0 – ∞		LED ID.
←	outStatus	int&			LED status.

AdvantechUNO_GetPowerStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the power status.

Syntax

```
void avl::AdvantechUNO_GetPowerStatus
(
 AdvantechUNO_State& ioState,
 int inVinId,
 int& outStatus
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
→	inVinId	int	0 – ∞		Vin ID.
←	outStatus	int&			Power status.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

- AdvantechUNO_SetPowerStatus – Sets the power status.

AdvantechUNO_GetUserData

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the user data space.

Syntax

```
void avl::AdvantechUNO_GetUserData
(
 AdvantechUNO_State& ioState,
 avl::ByteBuffer& outUserSpace1Data,
 avl::ByteBuffer& outUserSpace2Data
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	outUserSpace1Data	ByteBuffer&		User space 1 data.
	outUserSpace2Data	ByteBuffer&		User space 2 data.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

AdvantechUNO_GetUserDataLockStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the user data space lock status.

Syntax

```
void avl::AdvantechUNO_GetUserDataLockStatus
(
 AdvantechUNO_State& ioState,
 bool& outLocked
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	outLocked	bool&		User data lock status.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

AdvantechUNO_LockUserData

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Locks the user data space.

Syntax

```
void avl::AdvantechUNO_LockUserData
(
 AdvantechUNO_State& ioState,
 const atl::String& inPassword
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	inPassword	const String&		Password to lock the user data.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

AdvantechUNO_ReadDeviceData

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the device data.

Syntax

```
void avl::AdvantechUNO_ReadDeviceData
(
 AdvantechUNO_State& ioState,
 avl::ByteBuffer& outDeviceData
)
```

Parameters

	Name	Type	Default	Description
	ioState	AdvantechUNO_State&		Object used to maintain state of the function.
	outDeviceData	ByteBuffer&		Device data.

Remarks

I/O device driver software

This filter is intended to cooperate with an Advantech UNO series device using its vendor SDK. To be able to connect to the device, it is required to install PlatformSDK and device drivers.

Add DLL path to system environment variable may be required.

Recommended PlatformSDK version for Aurora Vision Studio usage is **V1.02.003 (1.2.3)**.

PlatformSDK can be downloaded from the following website: https://www.advantech.com/en-eu/search/?q=PlatformSDK&st=support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AdvantechUNO_SetBacklightBrightness

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the backlight brightness.

Syntax

```
void avl::AdvantechUNO_SetBacklightBrightness
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBacklight::Type& inBacklight,
 const atl::int64 inBrightnessLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
	inBacklight	AdvantechUNOBacklight::Type&			Backlight ID.
	inBrightnessLevel	const int64	0 – ∞		Brightness level.

Remarks

AdvantechUNO_SetBacklightLimits

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the display capabilities.

Syntax

```
void avl::AdvantechUNO_SetBacklightLimits
(
 AdvantechUNO_State& ioState,
 avl::AdvantechUNOBacklight::Type& inBacklight,
 atl::Optional<atl::int64> inMinBrightness,
 atl::Optional<atl::int64> inMaxBrightness,
 atl::Optional<bool> inAutoBrightness
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
	inBacklight	AdvantechUNOBacklight::Type&			Backlight ID.
	inMinBrightness	Optional<int64>	0 – ∞	NIL	Minimum brightness level.
	inMaxBrightness	Optional<int64>	0 – ∞	NIL	Maximum brightness level.
	inAutoBrightness	Optional<bool>		NIL	Turn auto brightness on/off.

Remarks

AdvantechUNO_SetGPIOPinDirection_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets GPIO directions.

Syntax

```
void avl::AdvantechUNO_SetGPIOPinDirection_Multiple
(
 AdvantechUNO_State& ioState,
 int inBank,
 atl::Optional<const atl::Array<bool>&> inMask,
 const atl::Array<avl::AdvantechUNOPinDirection::Type>& inDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AdvantechUNO_State&			Object used to maintain state of the function.
	inBank	int	0 – ∞	0	GPIO bank.
	inMask	Optional<const Array<bool>&>		NIL	GPIO mask.
	inDirection	const Array<AdvantechUNOPinDirection::Type>&			GPIO directions.

Remarks

AILDigitizer_Allocate

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Allocates a digitizer on specified system.

Syntax

```
void avl::AILDigitizer_Allocate
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_EnumerateAvailableCameras

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Enumerates available cameras.

Syntax

```
void avl::AILDigitizer_EnumerateAvailableCameras
(
 AIL_DigitizerState& ioState,
 atl::Optional<avl::AILDigitizerSystem::Type> inSystemType,
 atl::Array<avl::AILCameraInformation>& outDevices
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inSystemType	Optional<AILDigitizerSystem::Type>	NIL	Specifies for which system to enumerate the cameras. If not specified, all systems are enumerated.
	outDevices	Array<AILCameraInformation>&		List of available cameras.

Also in AVL Lite

AILDigitizer_EnumerateGenTLProducers

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Enumerates available GenTL producers.

Syntax

```
void avl::AILDigitizer_EnumerateGenTLProducers
(
 AIL_DigitizerState& ioState,
 atl::Array<atl::String>& outProducers
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	outProducers	Array<String>&		List of available GenTL producers.

Also in AVL Lite

AILDigitizer_ExecuteCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes command to the digitizer.

Syntax

```
void avl::AILDigitizer_ExecuteCommand
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inCommandName
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inCommandName	const String&		Name of the command.

Remarks

Warning: In the case of acquisition control, it is recommended to use the AILDigitizer_StartAcquisition, AILDigitizer_StopAcquisition, and AILDigitizer_GenerateSoftwareTrigger filters instead of commands.

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in **AVL Lite**

AILDigitizer_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger for digitizer.

Syntax

```
void avl::AILDigitizer_GenerateSoftwareTrigger
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_GetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a bool parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_GetBoolParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inParameterName	const String&		Name of the parameter.
←	outValue	bool&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_GetDoubleParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a double parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_GetDoubleParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inParameterName	const String&		Name of the parameter.
←	outValue	double&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_GetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enum parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_GetEnumParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inParameterName	const String&		Name of the parameter.
←	outValue	String&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

> **Note:** It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in **AVL Lite**

AILDigitizer_GetLongParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a long parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_GetLongParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 atl::sint64& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inParameterName	const String&		Name of the parameter.
←	outValue	sint64&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;

- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_GetStreamingStatistics

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets AIL digitizer streaming statistics.

Syntax

```
void avl::AILDigitizer_GetStreamingStatistics
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 avl::AILStreamingStatistics& outStatistics
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	outStatistics	AILStreamingStatistics&		Streaming statistics.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in **AVL Lite**

AILDigitizer_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a string parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_GetStringParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	outValue	String&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from the digitizer.

Syntax

```
bool avl::AILDigitizer_GrabImage
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 int inInputQueueSize,
 bool inSkipInvalidFrames,
 avl::Image& outImage,
 avl::AILFrameInformation& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AIL_DigitizerState&			Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>		NIL	Device identification.
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue.
→	inSkipInvalidFrames	bool		True	Skips invalid frames.
←	outImage	Image&			Captured image.
←	outFrameData	AILFrameInformation&			Frame data of the captured image.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from the digitizer with timeout.

Syntax

```
bool avl::AILDigitizer_GrabImage_WithTimeout
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 int inInputQueueSize,
 int inTimeout,
 bool inSkipInvalidFrames,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<avl::AILFrameInformation>& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AIL_DigitizerState&			Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>		NIL	Device identification.
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue.
→	inTimeout	int	100 – ∞	100	Maximum time to wait.
→	inSkipInvalidFrames	bool		True	Skips invalid frames.
←	outImage	Conditional<Image>&			Captured image.
←	outFrameData	Conditional<AILFrameInformation>&			Frame data of the captured image.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_GrabMultiPartImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a multi-part image from the digitizer. Allows to receive multi-part video stream (with multiple images per frame) from multi-component devices, like separate depth, confidence and luminosity images in 3D cameras.

Syntax

```
bool avl::AILDigitizer_GrabMultiPartImage
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 int inInputQueueSize,
 int inTimeout,
 bool inSkipInvalidFrames,
 atl::Conditional<avl::Image>& outFramePart1,
 atl::Conditional<avl::Image>& outFramePart2,
 atl::Conditional<avl::Image>& outFramePart3,
 atl::Conditional<avl::Image>& outFramePart4,
 atl::Conditional<avl::AILFrameInformation>& outFrameData,
 atl::Conditional<atl::sint64>& outFrameID,
 atl::Conditional<atl::sint64>& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AIL_DigitizerState&			Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>		NIL	Device identification.
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue.
→	inTimeout	int	100 – ∞	5000	Maximum time to wait for frame in milliseconds.
→	inSkipInvalidFrames	bool		True	Skips invalid frames.
←	outFramePart1	Conditional<Image>&			First part of the captured frame.
←	outFramePart2	Conditional<Image>&			Second part of the captured frame.
←	outFramePart3	Conditional<Image>&			Third part of the captured frame.
←	outFramePart4	Conditional<Image>&			Fourth part of the captured frame.
←	outFrameData	Conditional<AILFrameInformation>&			Frame data of the captured frame.
←	outFrameID	Conditional<sint64>&			Frame ID set by the device.
←	outTimestamp	Conditional<sint64>&			Frame capture timestamp set by the device.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;

AILDigitizer_SetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a bool parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_SetBoolParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	inValue	bool		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_SetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a double parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_SetDoubleParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	inValue	double		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an enum parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_SetEnumParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	inValue	const String&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_SetLongParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a long parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_SetLongParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 atl::sint64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	inValue	sint64		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

> **Note:** It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in **AVL Lite**

AILDigitizer_SetParameters

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameters for digitizer.

Syntax

```
void avl::AILDigitizer_SetParameters
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 atl::Optional<avl::AILDigitizerAutoExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 const atl::Optional<avl::AILDigitizerResolutionSettings>& inResolutionSettings,
 const atl::Optional<avl::AILDigitizerTriggerGrabSettings>& inTriggerSettings
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
→	inExposureMode	Optional<AILDigitizerAutoExposureMode::Type>	NIL	Automatic exposure mode setting
→	inExposureTime	Optional<int>	NIL	Exposure time setting in nanoseconds
→	inResolutionSettings	const Optional<AILDigitizerResolutionSettings>&	NIL	Digitizer resolution settings
→	inTriggerSettings	const Optional<AILDigitizerTriggerGrabSettings>&	NIL	Digitizer trigger settings

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

AILDigitizer_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a string parameter of the digitizer.

Syntax

```
void avl::AILDigitizer_SetStringParameter
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.
	inParameterName	const String&		Name of the parameter.
	inValue	const String&		Value of the parameter.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts acquisition of images from the digitizer.

Syntax

```
void avl::AILDigitizer_StartAcquisition
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID,
 int inInputQueueSize
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AIL_DigitizerState&			Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>		NIL	Device identification.
	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

AILDigitizer_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops acquisition of images from the digitizer.

Syntax

```
void avl::AILDigitizer_StopAcquisition
(
 AIL_DigitizerState& ioState,
 atl::Optional<const avl::AILSystemAndDeviceIdentifierDigitizer&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	AIL_DigitizerState&		Object used to maintain state of the function.
	inDeviceID	Optional<const AILSystemAndDeviceIdentifierDigitizer&>	NIL	Device identification.

Remarks

I/O device driver software

This filter is intended to cooperate with AIL digitizer systems:

- GigeVision – can work with cameras connected by Ethernet cable;
- GenTL – AIL specific devices like Matrox CoaXPress GenTL Producer;
- USB3Vision – can work with cameras connected by USB3 cable;
- RapixoCxp and RapixoCL – Rapixo frame grabbers for CoaXPress and Camera Link protocols;
- IrisGTX – Iris GTX Smart Camera;

To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version).

Adding the DLL path to system environment variables may be required.

Recommended Zebra AIL 11 SDK version for Aurora Vision Studio usage is **(11.00.0602)**.

Device identification

System field is used to specify camera protocol.

- **Host**
- **GigeVision**
- **GenTL**
- **USB3Vision**
- **RapixoCxp**
- **RapixoCL**
- **IrisGTX**

Device field specifies the hardware board identifier within the selected system. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

GenTLProducerIndex field is used to specify the index of the GenTL Producer – index is between 0 and 127. It is used only when **System** is set to **GenTL**.

Digitizer field specifies how the camera should be accessed. Digitizer can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).
- **CamIp** – Specifies that camera should connect using its IP address.
- **CamName** – Specifies that camera should connect using its name.

CamID field is used when Digitizer is set to CamIp or CamName.

Note: It is strongly recommended to set the appropriate **Device** and **Digitizer** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_ConfigureDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures digital input port.

Syntax

```
void avl::Z4Sight_ConfigureDigitalInput
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inInput,
 atl::Optional<int> inDebounceTime,
 atl::Optional<bool> inEnableGlitchFilter,
 atl::Optional<bool> inInvert
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInput	int	0 – 63		Input signal.
	inDebounceTime	Optional<int>	0 – ∞	NIL	Sets the amount of time that the specified auxiliary input signal is debounced. Specifies the minimum amount of time to ignore any additional signal transitions after accepting a signal transition, in ns.
	inEnableGlitchFilter	Optional<bool>		NIL	Sets whether to enable a glitch filter on input signals. A glitch is an unexpected signal transition of a short duration. Enabling the glitch filter will eliminate glitches of less than 500 ns on all input signals.
	inInvert	Optional<bool>		NIL	Sets whether the specified I/O signal should be inverted. This causes the low portion of the signal (the delay period) to be high and the high portion of the signal (the active portion) to be low.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_ConfigureDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures digital output.

Syntax

```
void avl::Z4Sight_ConfigureDigitalOutput
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inOutput,
 atl::Optional<bool> inInvert,
 atl::Optional<const avl::Z4SightOutputSourceValue&> inOutputSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inOutput	int	0 - 63		Output signal.
	inInvert	Optional<bool>		NIL	Sets whether the specified I/O signal should be inverted. This causes the low portion of the signal (the delay period) to be high and the high portion of the signal (the active portion) to be low.
	inOutputSource	Optional<const Z4SightOutputSourceValue&>		NIL	Sets the type of signal to route to an output signal

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_ConfigureEncoder

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures the encoder.

Syntax

```
void avl::Z4Sight_ConfigureEncoder
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inEncoder,
 int inBit0Source,
 int inBit1Source,
 avl::Z4SightEncoderOutputMode::Type inOutputMode,
 int inPositionTrigger,
 avl::Z4SightEncoderResetSource::Type inResetSource,
 bool inResetCounter,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inEncoder	int	1 - 2		Encoder.
	inBit0Source	int	0 - 63	1	Auxiliary input signal on which to receive bit 0 of the 2-bit Gray code.
	inBit1Source	int	0 - 63	2	Auxiliary input signal on which to receive bit 1 of the 2-bit Gray code.
	inOutputMode	Z4SightEncoderOutputMode::Type			Circumstances in which the rotary decoder should output a pulse.
	inPositionTrigger	int			Rotary decoder's counter value upon which a trigger is generated.
	inResetSource	Z4SightEncoderResetSource::Type			Signal source to use to reset the rotary decoder's counter to 0.
	inResetCounter	bool			Reset the encoder counter value to 0 at the end of configuration.
	inEnable	bool		True	Enable or disable the encoder.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to configure one of the built-in quadrature decoders.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_EnableEncoder - Enables or disables the encoder.

Z4Sight_ConfigureIOCommandList

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures an I/O command list.

Syntax

```
void avl::Z4Sight_ConfigureIOCommandList
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 avl::Z4SightIOCommandListCounterSource::Type inCounterSource,
 atl::Optional<avl::Z4SightCommandCounterActivation::Type> inCounterActivation,
 double& outClockFrequency
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inCommandList	int	1 - 2		I/O command list.
	inCounterSource	Z4SightIOCommandListCounterSource::Type			Counter source for the command list.
	inCounterActivation	Optional<Z4SightCommandCounterActivation::Type>		NIL	Counter activation for the command list.
	outClockFrequency	double&			Frequency of the I/O command list's clock signal

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to configure one of the I/O command lists.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_ConfigureLatch

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures the latch.

Syntax

```
void avl::Z4Sight_ConfigureLatch
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inLatch,
 int inCommandList,
 avl::Z4SightLatchTriggerSource::Type inTriggerSource,
 avl::Z4SightLatchTriggerActivation::Type inActivation,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inLatch	int	1 - 4		Latch.
	inCommandList	int	1 - 2		CommandList to which bind a latch.
	inTriggerSource	Z4SightLatchTriggerSource::Type		Input0	Trigger source for the latch.
	inActivation	Z4SightLatchTriggerActivation::Type		EdgeRising	Signal variation upon which to generate a latch trigger.
	inEnable	bool		True	Enable or disable the latch.

Remarks

Z4Sight_ConfigureTimer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures the timer.

Syntax

```
void avl::Z4Sight_ConfigureTimer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimer,
 bool inArmEnable,
 avl::Z4SightTimerTriggerActivation::Type inArmActivation,
 atl::Optional<avl::Z4SightArmTimerTriggerSource::Type> inArmTriggerSource,
 avl::Z4SightTimerTriggerSource::Type inTriggerSource,
 avl::Z4SightTimerTriggerOverlap::Type inTriggerOverlap,
 atl::Optional<avl::Z4SightTimerSource::Type> inClockSource,
 atl::Optional<avl::Z4SightTimerSource::Type> inDelaySource,
 atl::int64 inDelay,
 atl::int64 inDuration,
 bool inInvert,
 avl::Z4SightTimerTriggerActivation::Type inActivation,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inTimer	int	1 – 16		Timer.
	inArmEnable	bool			Specifies if timer arming is enabled or not.
	inArmActivation	Z4SightTimerTriggerActivation::Type		EdgeRising	Specifies timer arm activation signal
	inArmTriggerSource	Optional<Z4SightArmTimerTriggerSource::Type>		NIL	Sets which input signal will arm the timer, if timer arming is enabled.
	inTriggerSource	Z4SightTimerTriggerSource::Type		Continuous	Trigger source for the timer.
	inTriggerOverlap	Z4SightTimerTriggerOverlap::Type		Off	Specifies Trigger overlap mode
	inClockSource	Optional<Z4SightTimerSource::Type>		NIL	Clock source for the timer.
	inDelaySource	Optional<Z4SightTimerSource::Type>		NIL	Delay source for the timer.
	inDelay	int64	0 – ∞	1000000L	Delay between the timer trigger and the active portion of the timer output signal (in ns for clock source, in the number of counts for the rest).
	inDuration	int64	0 – ∞	1000000L	Duration for the active portion of the timer output signal (in ns for clock source, in the number of counts for the rest).
	inInvert	bool		False	Whether to invert the output signal or not.
	inActivation	Z4SightTimerTriggerActivation::Type			Signal variation upon which to generate a timer trigger.
	inEnable	bool		True	Enable or disable the timer.

Remarks

I/O device driver software

- Z4Sight_EnableTimer – Enables or disables the timer.

Z4Sight_EnableEncoder

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Enables or disables the encoder.

Syntax

```
void avl::Z4Sight_EnableEncoder
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inEncoder,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inEncoder	int	1 - 2		Encoder.
	inEnable	bool		True	Enable or disable the timer.

Z4Sight_EtherNetIP_Read_ByteBuffer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the assembly data as a ByteBuffer.

Syntax

```
void avl::Z4Sight_EtherNetIP_Read_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 int inCount,
 avl::ByteBuffer& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified assembly.
→	inCount	int	1 – ∞		Amount of the data to read.
←	outValues	ByteBuffer&			Received values.

Z4Sight_EtherNetIP_Read_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the assembly data as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Read_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified assembly.
→	inCount	int	1 – ∞		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for data in the memory.
←	outValues	Array<float>&			Received values.

Z4Sight_EtherNetIP_Read_sint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the assembly data as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Read_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified assembly.
→	inCount	int	1 – ∞		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for data in the memory.
←	outValues	Array<int>&			Received values.

Z4Sight_EtherNetIP_Read_sint32

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the assembly data as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Read_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified assembly.
→	inCount	int	1 – ∞		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for data in the memory.
←	outValues	Array<int>&			Received values.

Z4Sight_EtherNetIP_Read_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the assembly data as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Read_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified assembly.
→	inCount	int	1 – ∞		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for data in the memory.
←	outValues	Array<int>&			Received values.

Z4Sight_EtherNetIP_Write_ByteBuffer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the assembly data as a ByteBuffer.

Syntax

```
void avl::Z4Sight_EtherNetIP_Write_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 const avl::ByteBuffer& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified assembly.
	inValues	const ByteBuffer&			Values to write.

Z4Sight_EtherNetIP_Write_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the assembly data as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Write_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<float>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified assembly.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<float>&			Values to write.

Z4Sight_EtherNetIP_Write_sint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the assembly data as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Write_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified assembly.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_EtherNetIP_Write_sint32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the assembly data as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Write_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified assembly.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_EtherNetIP_Write_uint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the assembly data as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_EtherNetIP_Write_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightEtherNetIPAssembly::Type inAssembly,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inAssembly	Z4SightEtherNetIPAssembly::Type		Consumer	Assembly in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified assembly.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger for the timer.

Syntax

```
void avl::Z4Sight_GenerateSoftwareTrigger
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inTimer	int	1 - 16		Timer.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to generate a software trigger for one of the timers. The specified timer must be configured to use the **Software** trigger source using the **Z4Sight_ConfigureTimer** filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_ConfigureTimer - Configures the timer.

Z4Sight_GetAllInputLevels

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the state of all the inputs on the device.

Syntax

```
void avl::Z4Sight_GetAllInputLevels
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inStart,
 int inEnd,
 atl::Array<bool>& outLevels
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inStart	int	0 – 63		Index of first input port.
→	inEnd	int	0 – 63		Index of last input port.
←	outLevels	Array<bool>&			Logic levels of the I/Os.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to get the information about the logical level of all input ports of the device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- Z4Sight_GetInputLevel – Gets input signal level.

Z4Sight_GetCounterReferenceValue

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the I/O command list's internal counter value at the current moment.

Syntax

```
void avl::Z4Sight_GetCounterReferenceValue
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 atl::int64& outReferenceValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inCommandList	int	1 - 2		I/O command list.
←	outReferenceValue	int64&			Command list's internal counter value.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to obtain the current value of an I/O command list's counter. This value can later be used to register events at precise moments of time in relation to that value.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- Z4Sight_RegisterPulse - Registers a pulse in a command list.
- Z4Sight_RegisterImpulse - Registers an impulse in a command list.

Z4Sight_GetEncoderCounter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the current value of an encoder counter.

Syntax

```
void avl::Z4Sight_GetEncoderCounter
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inEncoder,
 int& outCounterValue
)
```

Parameters

	Name	Type	Range	Default	Description
⇆	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inEncoder	int	1 - 2		Encoder.
←	outCounterValue	int&			Value of the encoder counter.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to obtain the current value of the encoder counter for one of the quadrature decoders.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_GetEndTimerWatcherEvent

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetEndTimerWatcherEvent
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 avl::Z4SightEvent& outEvent
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Z4Sight_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
←	outEvent	Z4SightEvent&		

Also in AVL Lite

Z4Sight_GetEndTimerWatcherEvent_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetEndTimerWatcherEvent_WithTimeout
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimeout,
 atl::Conditional<avl::Z4SightEvent>& outEvent
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Z4Sight_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
→	inTimeout	int		Maximum time to wait.
←	outEvent	Conditional<Z4SightEvent>&		

Z4Sight_GetInputLevel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets input signal level.

Syntax

```
void avl::Z4Sight_GetInputLevel
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inInput,
 atl::Optional<int> inDebounceTime,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInput	int	0 – 63		Input signal.
→	inDebounceTime	Optional<int>	0 – ∞	NIL	Amount of time the input signal is debounced (in ns).
←	outLevel	bool&			Logic level of the input signal.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

Z4Sight_GetIOWatcherEvent

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetIOWatcherEvent
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 avl::Z4SightEvent& outEvent
)
```

Parameters

	Name	Type	Default	Description
	ioState	Z4Sight_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
	outEvent	Z4SightEvent&		

Also in AVL Lite

Z4Sight_GetIOWatcherEvent_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetIOWatcherEvent_WithTimeout
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimeout,
 atl::Conditional<avl::Z4SightEvent>& outEvent
)
```

Parameters

	Name	Type	Default	Description
	ioState	Z4Sight_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
	inTimeout	int		Maximum time to wait.
	outEvent	Conditional<Z4SightEvent>&		

Also in AVL Lite

Z4Sight_GetStartTimerWatcherEvent

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetStartTimerWatcherEvent
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 avl::Z4SightEvent& outEvent
)
```

Parameters

	Name	Type	Default	Description
	ioState	Z4Sight_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
	outEvent	Z4SightEvent&		

Also in AVL Lite

Z4Sight_GetStartTimerWatcherEvent_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get io hook event.

Syntax

```
void avl::Z4Sight_GetStartTimerWatcherEvent_WithTimeout
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimeout,
 atl::Conditional<avl::Z4SightEvent>& outEvent
)
```

Parameters

	Name	Type	Default	Description
	ioState	Z4Sight_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification number.
	inTimeout	int		Maximum time to wait.
	outEvent	Conditional<Z4SightEvent>&		

Z4Sight_GetTimerValue

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets timer value.

Syntax

```
void avl::Z4Sight_GetTimerValue
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimer,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inTimer	int	1 – 16		Timer.
←	outValue	int64&			Timer value. in ns for clock source, in the number of counts for the rest

Also in AVL Lite

Z4Sight_Modbus_ReadCoils

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the coil data table in local memory for data received from a Modbus controller.

Syntax

```
void avl::Z4Sight_Modbus_ReadCoils
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<bool>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
→	inCount	int	1 – 2000		Amount of the data to read.
←	outValues	Array<bool>&			Received values.

Also in AVL Lite

Z4Sight_Modbus_ReadDiscreteInputs

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the discrete input data table in local memory for data received from a Modbus controller.

Syntax

```
void avl::Z4Sight_Modbus_ReadDiscreteInputs
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<bool>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 2000		Amount of the data to read.
	outValues	Array<bool>&			Received values.

Also in AVL Lite

Z4Sight_Modbus_ReadHoldingRegisters_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the holding register data table as a ByteBuffer.

Syntax

```
void avl::Z4Sight_Modbus_ReadHoldingRegisters_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 avl::ByteBuffer& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 125		Amount of the data to read.
	outValues	ByteBuffer&			Received values.

Z4Sight_Modbus_ReadHoldingRegisters_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the holding register data table as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_Modbus_ReadHoldingRegisters_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65534		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 62		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for words in the registers.
	outValues	Array<float>&			Received values.

Z4Sight_Modbus_ReadHoldingRegisters_sint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the holding register data table as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadHoldingRegisters_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
→	inCount	int	1 – 125		Amount of the data to read.
←	outValues	Array<int>&			Received values.

Z4Sight_Modbus_ReadHoldingRegisters_sint32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the holding register data table as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadHoldingRegisters_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65534		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 62		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for words in the registers.
	outValues	Array<int>&			Received values.

Z4Sight_Modbus_ReadHoldingRegisters_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the holding register data table as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadHoldingRegisters_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 125		Amount of the data to read.
	outValues	Array<int>&			Received values.

Z4Sight_Modbus_ReadInputRegisters_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the input register data table as a ByteBuffer.

Syntax

```
void avl::Z4Sight_Modbus_ReadInputRegisters_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 avl::ByteBuffer& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 125		Amount of the data to read.
	outValues	ByteBuffer&			Received values.

Z4Sight_Modbus_ReadInputRegisters_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the input register data table as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_Modbus_ReadInputRegisters_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inOffset	int	0 – 65534		Offset from which to start reading the data in the specified data table.
→	inCount	int	1 – 62		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for words in the registers.
←	outValues	Array<float>&			Received values.

Z4Sight_Modbus_ReadInputRegisters_sint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the input register data table as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadInputRegisters_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
→	inCount	int	1 – 125		Amount of the data to read.
←	outValues	Array<int>&			Received values.

Z4Sight_Modbus_ReadInputRegisters_sint32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the input register data table as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadInputRegisters_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65534		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 62		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for words in the registers.
	outValues	Array<int>&			Received values.

Z4Sight_Modbus_ReadInputRegisters_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the input register data table as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_ReadInputRegisters_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 int inCount,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset from which to start reading the data in the specified data table.
	inCount	int	1 – 125		Amount of the data to read.
	outValues	Array<int>&			Received values.

Z4Sight_Modbus_WriteCoils

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the coil data table in local memory to send to the Modbus controller.

Syntax

```
void avl::Z4Sight_Modbus_WriteCoils
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 const atl::Array<bool>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset to which to start writing the data in the specified data table.
	inValues	const Array<bool>&			Values to write.

Z4Sight_Modbus_WriteHoldingRegisters_ByteBuffer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the holding register data table as a ByteBuffer.

Syntax

```
void avl::Z4Sight_Modbus_WriteHoldingRegisters_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 const avl::ByteBuffer& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset to which to start writing the data in the specified data table.
	inValues	const ByteBuffer&			Values to write.

Z4Sight_Modbus_WriteHoldingRegisters_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the holding register data table as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_Modbus_WriteHoldingRegisters_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<float>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65534		Offset to which to start writing the data in the specified data table.
	inUseLittleEndian	bool			Use little endian order for words in the registers.
	inValues	const Array<float>&			Values to write.

Also in AVL Lite

Z4Sight_Modbus_WriteHoldingRegisters_sint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the holding register data table as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_WriteHoldingRegisters_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65535		Offset to which to start writing the data in the specified data table.
	inValues	const Array<int>&			Values to write.

Also in AVL Lite

Z4Sight_Modbus_WriteHoldingRegisters_sint32

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the holding register data table as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_WriteHoldingRegisters_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inOffset	int	0 – 65534		Offset to which to start writing the data in the specified data table.
	inUseLittleEndian	bool			Use little endian order for words in the registers.
	inValues	const Array<int>&			Values to write.

Also in AVL Lite

Z4Sight_Modbus_WriteHoldingRegisters_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the holding register data table as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_Modbus_WriteHoldingRegisters_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inOffset,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inOffset	int	0 – 65535		Offset to which to start writing the data in the specified data table.
→	inValues	const Array<int>&			Values to write.

Also in AVL Lite

Z4Sight_Profinet_GetControllerState

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the state of the PROFINET controller (PLC) connected to the local computer.

Syntax

```
void avl::Z4Sight_Profinet_GetControllerState
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 avl::Z4SightProfinetPlcStatus::Type& outStatus,
 avl::Z4SightProfinetPlcMode::Type& outMode
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Z4Sight_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>	NIL	Device identification.
→	inInstanceName	const Optional<String>&	NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
←	outStatus	Z4SightProfinetPlcStatus::Type&		Status of the PROFINET controller.
←	outMode	Z4SightProfinetPlcMode::Type&		Mode of the PROFINET controller.

Z4Sight_Profinet_Read_ByteBuffer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the module data as a ByteBuffer.

Syntax

```
void avl::Z4Sight_Profinet_Read_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 int inCount,
 avl::ByteBuffer& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory from which to read the data.
	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified module.
	inCount	int	1 – ∞		Amount of the data to read.
	outValues	ByteBuffer&			Received values.

Z4Sight_Profinet_Read_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the module data as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_Profinet_Read_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<float>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory from which to read the data.
	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified module.
	inCount	int	1 – ∞		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	outValues	Array<float>&			Received values.

Z4Sight_Profinet_Read_sint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the module data as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Read_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory from which to read the data.
	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified module.
	inCount	int	1 – ∞		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	outValues	Array<int>&			Received values.

Z4Sight_Profinet_Read_sint32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the module data as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Read_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
→	inModuleIndex	int	0 – 255		Index of the module in local memory from which to read the data.
→	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified module.
→	inCount	int	1 – ∞		Amount of the data to read.
→	inUseLittleEndian	bool			Use little endian order for data in the memory.
←	outValues	Array<int>&			Received values.

Z4Sight_Profinet_Read_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the module data as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Read_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 int inCount,
 bool inUseLittleEndian,
 atl::Array<int>& outValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory from which to read the data.
	inOffset	int	0 – ∞		Offset from which to start reading the data in the specified module.
	inCount	int	1 – ∞		Amount of the data to read.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	outValues	Array<int>&			Received values.

Z4Sight_Profinet_Write_ByteBuffer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the module data as a ByteBuffer.

Syntax

```
void avl::Z4Sight_Profinet_Write_ByteBuffer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 const avl::ByteBuffer& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified module.
	inValues	const ByteBuffer&			Values to write.

Z4Sight_Profinet_Write_float32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the module data as 32-bit floating point numbers.

Syntax

```
void avl::Z4Sight_Profinet_Write_float32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<float>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified module.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<float>&			Values to write.

Z4Sight_Profinet_Write_sint16

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the module data as signed 16-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Write_sint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified module.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_Profinet_Write_sint32

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the module data as signed 32-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Write_sint32
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified module.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_Profinet_Write_uint16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes the module data as unsigned 16-bit integers.

Syntax

```
void avl::Z4Sight_Profinet_Write_uint16
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 const atl::Optional<atl::String>& inInstanceName,
 int inModuleIndex,
 int inOffset,
 bool inUseLittleEndian,
 const atl::Array<int>& inValues
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inInstanceName	const Optional<String>&		NIL	Instance name of a given Industrial Communication protocol set in the MILConfig utility.
	inModuleIndex	int	0 – 255		Index of the module in local memory to which to write the data.
	inOffset	int	0 – ∞		Offset to which to start writing the data in the specified module.
	inUseLittleEndian	bool			Use little endian order for data in the memory.
	inValues	const Array<int>&			Values to write.

Z4Sight_RegisterCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Register command.

Syntax

```
void avl::Z4Sight_RegisterCommand
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 const avl::Z4SightCommand& inCommand,
 atl::Optional<avl::Z4SightCommandRegister::Type> inCommandRegister,
 atl::Optional<int> inLatchNumber,
 atl::Optional<atl::int64> inReferenceMoment
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification number.
	inCommandList	int	1 - 2		I/O command list.
	inCommand	const Z4SightCommand&			Command details.
	inCommandRegister	Optional<Z4SightCommandRegister::Type>		NIL	Command register for auto mode.
	inLatchNumber	Optional<int>	1 - 4	NIL	Latch number, only for auto mode.
	inReferenceMoment	Optional<int64>	0 - ∞	NIL	Reference value or current if not set, only for no auto mode.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

Z4Sight_RegisterEdge

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Registers an edge in a command list.

Syntax

```
void avl::Z4Sight_RegisterEdge
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 int inCommandBit,
 avl::Z4SightEdgeType::Type inEdgeType,
 atl::Optional<atl::int64> inReferenceMoment,
 float inDelay
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inCommandList	int	1 – 2		I/O command list.
→	inCommandBit	int	0 – 7		Bit of the command list.
→	inEdgeType	Z4SightEdgeType::Type			Type of the edge to register.
→	inReferenceMoment	Optional<int64>		NIL	Value of counter for which the command is to be registered (in seconds or counts).
→	inDelay	float	0.0 – ∞	0.0f	Delay from the specified counter value.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to register an edge in one of the command lists. The specified command list must be configured using **Z4Sight_ConfigureIOCommandList** prior to using this filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- Z4Sight_RegisterImpulse – Registers an impulse in a command list.

Z4Sight_RegisterEndTimerWatcher

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Register hook function and invoke command.

Syntax

```
void avl::Z4Sight_RegisterEndTimerWatcher
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 atl::Optional<int> inInputQueueSize,
 int inTimer,
 const atl::Array<avl::Z4SightHook>& inHooks
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification number.
	inInputQueueSize	Optional<int>		NIL	Capacity of output frames queue.
	inTimer	int	1 – 16		Timer to watch.
	inHooks	const Array<Z4SightHook>&			Hook to perform and latch to watch.

Z4Sight_RegisterImpulse

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Registers an impulse in a command list.

Syntax

```
void avl::Z4Sight_RegisterImpulse
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 int inCommandBit,
 atl::Optional<atl::int64> inReferenceMoment,
 float inDelay
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inCommandList	int	1 – 2		I/O command list.
	inCommandBit	int	0 – 7		Bit of the command list.
	inReferenceMoment	Optional<int64>		NIL	Value of counter for which the command is to be registered (in seconds or counts).
	inDelay	float	0.0 – ∞	0.0f	Delay from the specified counter value.

Remarks

I/O device driver software

- Z4Sight_RegisterPulse – Registers a pulse in a command list.

Z4Sight_RegisterIOWatcher

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Register hook function and invoke command.

Syntax

```
void avl::Z4Sight_RegisterIOWatcher
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 atl::Optional<int> inInputQueueSize,
 int inInput,
 avl::Z4SightEdgeType::Type inActivation,
 const atl::Array<avl::Z4SightHook>& inHooks
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification number.
	inInputQueueSize	Optional<int>		NIL	Capacity of output frames queue.
	inInput	int	0 – 63		Input to watch.
	inActivation	Z4SightEdgeType::Type			Type of the edge to register.
	inHooks	const Array<Z4SightHook>&			Hook to perform and latch to watch.

Z4Sight_RegisterPulse

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Registers a pulse in a command list.

Syntax

```
void avl::Z4Sight_RegisterPulse
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 int inCommandBit,
 avl::Z4SightPulseType::Type inPulseType,
 atl::Optional<atl::int64> inReferenceMoment,
 float inDelay,
 float inDuration
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inCommandList	int	1 – 2		I/O command list.
	inCommandBit	int	0 – 7		Bit of the command list.
	inPulseType	Z4SightPulseType::Type			Type of the pulse to register.
	inReferenceMoment	Optional<int64>		NIL	Value of counter for which the command is to be registered (in seconds or counts).
	inDelay	float	0.0 – ∞	0.0f	Delay from the specified counter value.
	inDuration	float	0.0 – ∞	0.01f	Duration of the pulse.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to register a pulse in one of the command lists. The specified command list must be configured using **Z4Sight_ConfigureIOCommandList** prior to using this filter.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_ConfigureIOCommandList – Configures an I/O command list.
- Z4Sight_GetCounterReferenceValue – Gets the I/O command list's internal counter value at the current moment.
- Z4Sight_RegisterEdge – Registers an edge in a command list.
- Z4Sight_RegisterImpulse – Registers an impulse in a command list.

Z4Sight_RegisterStartTimerWatcher

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Register hook function and invoke command.

Syntax

```
void avl::Z4Sight_RegisterStartTimerWatcher
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 atl::Optional<int> inInputQueueSize,
 int inTimer,
 const atl::Array<avl::Z4SightHook>& inHooks
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification number.
	inInputQueueSize	Optional<int>		NIL	Capacity of output frames queue.
	inTimer	int	1 – 16		Timer to watch.
	inHooks	const Array<Z4SightHook>&			Hook to perform and latch to watch.

Z4Sight_ResetEncoderCounter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets the value of an encoder counter.

Syntax

```
void avl::Z4Sight_ResetEncoderCounter
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inEncoder
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inEncoder	int	1 - 2		Encoder.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to reset the value of the encoder counter to 0.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_GetEncoderCounter - Gets the current value of an encoder counter.

Z4Sight_ResetTimer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets specified timer.

Syntax

```
void avl::Z4Sight_ResetTimer
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inTimer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inTimer	int	1 – 16		Timer.

Z4Sight_SetInputDebounceTime

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set input signal debounce.

Syntax

```
void avl::Z4Sight_SetInputDebounceTime
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inInput,
 int inDebounceTime
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Z4Sight_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
→	inInput	int	0 – 63		Input signal.
→	inDebounceTime	int	0 – ∞		Amount of time the input signal is debounced (in ns).

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_SetOutputLevel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output signal level.

Syntax

```
void avl::Z4Sight_SetOutputLevel
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inOutput,
 bool inLevel,
 bool inForceUserOutputSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inOutput	int	0 - 63		Output signal.
	inLevel	bool			Logic level of the output signal.
	inForceUserOutputSource	bool			Whether to set the output source to user bit or not.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to set the logical level of a specific output port of the device.

Setting the output source

The source of the specific output port must be set to **User** using Z4Sight_SetOutputSource filter first for this filter to take effect. It is also possible to force an automatic change of the output source by setting the **inForceUserOutputSource** field value to **true**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_SetOutputSource - Sets output signal source.

Z4Sight_SetOutputSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output signal source.

Syntax

```
void avl::Z4Sight_SetOutputSource
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inOutput,
 avl::Z4SightOutputSource::Type inSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inOutput	int	0 - 63		Output signal.
	inSource	Z4SightOutputSource::Type			Source signal routed to the output signal.

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** - Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** - Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** - Specifies the default build-in system like IO in industrial PC.
- **CONCORD** - Specifies the IO system from Concord framegrabber.
- **INDIO** - Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

This filter allows to route a source to a specific output port of the device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Z4Sight_SetOutputLevel - Sets output signal level.

Z4Sight_SetUserBit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set value of user bit

Syntax

```
void avl::Z4Sight_SetUserBit
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inBitIndex,
 bool inValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification.
	inBitIndex	int	0 – 63		User bit index
	inValue	bool			Value to be set

Remarks

I/O device driver software

This filter is intended to cooperate with Zebra 4Sight devices, Zebra Indio I/O Cards and Zebra Concord Frame Grabbers using their vendor SDK. To be able to connect to the device, it is required to install Zebra AIL X SDK (Lite or Full version). Zebra 4Sight industrial PCs usually come with a preinstalled runtime license.

Add DLL path to system environment variable may be required.

Recommended Zebra AIL X SDK version for Aurora Vision Studio usage is **V22H1 (10.60.0776)**.

Device identification

Device field can be used to specify the number (rank) of the target board of the specified system type. Device can be set to:

- **DEFAULT** – Specifies the default board. The default board is set in the MILConfig utility.
- **DEVn** – Specifies the device number (rank) of the board (where 0 <= n <=15).

System field can be used to specify the system type. System can be set to:

- **HOST** – Specifies the default build-in system like IO in industrial PC.
- **CONCORD** – Specifies the IO system from Concord framegrabber.
- **INDIO** – Specifies the IO system from Concord IO Card.

Note: It is strongly recommended to set the appropriate **System** parameter to avoid communication issues.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Z4Sight_UnregisterCommand

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Unregister command. For the pulse signal, the falling edge is cancelled only if the rising edge cancellation was successful.

Syntax

```
void avl::Z4Sight_UnregisterCommand
(
 Z4Sight_State& ioState,
 atl::Optional<const avl::Z4SightSystemAndDeviceIdentifier&> inDeviceID,
 int inCommandList,
 int inCommandBit,
 float inDelay,
 atl::Optional<float> inDuration,
 atl::int64 inReference
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Z4Sight_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const Z4SightSystemAndDeviceIdentifier&>		NIL	Device identification number.
	inCommandList	int	1 – 2		I/O command list.
	inCommandBit	int	0 – 7		Bit of the command list.
	inDelay	float	0.0 – ∞	0.0f	Command delay in seconds.
	inDuration	Optional<float>		NIL	Command duration, only for pulse to unregister it in right way.
	inReference	int64

AvSMART_ConfigureLEDDriverMode

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set the driver working mode of LED.

Syntax

```
void avl::AvSMART_ConfigureLEDDriverMode
(
 AvSmart_State& ioState,
 avl::RoseekLEDDriverType::Type inType,
 avl::RoseekLEDDriverMode::Type inMode
)
```

Parameters

	Name	Type	Default	Description
	ioState	AvSmart_State&		Object used to maintain state of the function.
	inType	RoseekLEDDriverType::Type		Driver type (own or external)
	inMode	RoseekLEDDriverMode::Type		LED driver mode

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

AvSMART_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::AvSMART_GenerateSoftwareTrigger
(
 AvSmart_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	AvSmart_State&		Object used to maintain state of the function.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_GetInputState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get input I/O state.

Syntax

```
void avl::AvSMART_GetInputState
(
 AvSmart_State& ioState,
 int inId,
 bool& outState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AvSmart_State&			Object used to maintain state of the function.
	inId	int	0 - 7		Index of I/O output port
	outState	bool&			Received state

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a AvSMART device.

Syntax

```
bool avl::AvSMART_GrabImage
(
 AvSmart_State& ioState,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 avl::Image& outImage,
 int& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	AvSmart_State&			Object used to maintain state of the function.
→	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
→	inImageFormat	RoseekImageFormat::Type			Image pixel format
→	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
→	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI.
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Image&			Captured frame
←	outFrameID	int&			Captured frame ID

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a AvSMART device.

Applications: Use this filter if the trigger may be not coming for some time, while the application should perform other operations in the main loop continuously, or when the timeout situation must be explicitly detected, or when you want to process images from multiple cameras in a single loop and the cameras are sending images asynchronously.

Syntax

```
bool avl::AvSMART_GrabImage_WithTimeout
(
 AvSmart_State& ioState,
 int inTimeout,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<int>& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	AvSmart_State&			Object used to maintain state of the function.
→	inTimeout	int	10 – 3600000		Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
→	inImageFormat	RoseekImageFormat::Type			Image pixel format
→	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
→	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI.
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int>&			Captured frame ID

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_SetLEDDriverStrength

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set the driver strength of LED.

Syntax

```
void avl::AvSMART_SetLEDDriverStrength
(
 AvSmart_State& ioState,
 avl::RoseekLEDDriverType::Type inType,
 int inStrength
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AvSmart_State&			Object used to maintain state of the function.
	inType	RoseekLEDDriverType::Type			Driver type (own or external)
	inStrength	int	0 – 1500		Strength. For OWN driver type the max value is 330 otherwise 1500

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_SetOutputState

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set output I/O state.

Syntax

```
void avl::AvSMART_SetOutputState
(
 AvSmart_State& ioState,
 int inId,
 bool inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AvSmart_State&			Object used to maintain state of the function.
	inId	int	0 – 7		Index of I/O output port
	inState	bool			true = TURN_ON, false = TURN_OFF

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_SetStatusLED

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set the status of programmable LED state indicators supported on the camera.

Syntax

```
void avl::AvSMART_SetStatusLED
(
 AvSmart_State& ioState,
 int inId,
 avl::RoseekLEDStatus::Type inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AvSmart_State&			Object used to maintain state of the function.
	inId	int	0 – 2		Index of I/O output port
	inState	RoseekLEDStatus::Type			Received state

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition.

Syntax

```
void avl::AvSMART_StartAcquisition
(
 AvSmart_State& ioState,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AvSmart_State&			Object used to maintain state of the function.
	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
	inImageFormat	RoseekImageFormat::Type			Image pixel format
	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI.
	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

AvSMART_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition.

Syntax

```
void avl::AvSMART_StopAcquisition
(
 AvSmart_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	AvSmart_State&		Object used to maintain state of the function.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

160. AXIS

Table of content:

- AXIS_StartAcquisition
- AXIS_StopAcquisition
- AXIS_WriteDigitalPortStatus

AXIS_ConfigureDigitalIO

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures AXIS digital IO.

Syntax

```
void avl::AXIS_ConfigureDigitalIO
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 int inPort,
 bool inIsInput,
 bool inIsClosed
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 – 4		ID of camera
	inLogin	Optional<const String&>		NIL	Login for Basic authorization
	inPassword	Optional<const String&>		NIL	Login for Basic authorization
	inPort	int	0 – ∞		Port number
	inIsInput	bool			Port type. If possible, type will be forced to device
	inIsClosed	bool			Port working mode

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inAddress in AXIS_ConfigureDigitalIO.

AXIS_GenericRequest

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Send basic GET HTTP request to AXIS device.

Syntax

```
void avl::AXIS_GenericRequest
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 const atl::String& inRequest,
 atl::String& outResponse
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 - 4		ID of camera
	inLogin	Optional<const String&>		NIL	Login for Basic authorization
	inPassword	Optional<const String&>		NIL	Login for Basic authorization
	inRequest	const String&			The url part that follows the device address.
	outResponse	String&			Response limited to 1024 lines.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inAddress in AXIS_GenericRequest.

AXIS_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using AXIS.

Syntax

```
bool avl::AXIS_GrabImage
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 int inOutputQueueSize,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 atl::Optional<const atl::String&> inStreamProfile,
 atl::Optional<avl::AXISResolution::Type> inResolution,
 atl::Optional<avl::AXISRotation::Type> inRotation,
 atl::Optional<int> inCompression,
 atl::Optional<const atl::String&> inTextString,
 atl::Optional<bool> inUseSquarePixel,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AXIS_State&			Object used to maintain state of the function.
→	inAddress	const String&			Source device host or ip address
→	inCameraID	int	1 – 4		ID of camera
→	inOutputQueueSize	int	5 – 200		Capacity of output frames queue
→	inLogin	Optional<const String&>		NIL	Login for Basic authorization
→	inPassword	Optional<const String&>		NIL	Login for Basic authorization
→	inStreamProfile	Optional<const String&>		NIL	Profile configuration name.
→	inResolution	Optional<AXISResolution::Type>		NIL	Resolution of the returned image
→	inRotation	Optional<AXISRotation::Type>		NIL	Rotates the image clockwise
→	inCompression	Optional<int>	0 – 100	NIL	Compression level of the image
→	inTextString	Optional<const String&>		NIL	
→	inUseSquarePixel	Optional<bool>		NIL	Square pixel (aspect ratio) correction
←	outImage	Image&			Output image

Remarks

Camera identification

Camera is identified by two inputs:

- inAddress – server name or IP address of camera. It is not a http address using to view image by website. For example:

  ```
  http://my.camera.com/folder/view/viewer_index.shtml?id=217
  ```

  inAddress is

  ```
  http://my.camera.com
  ```

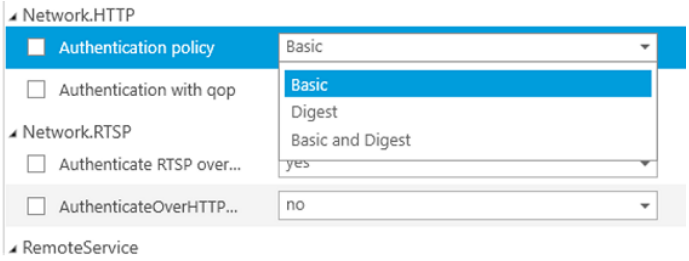
- inCameraID – camera source. Applies only to video servers with more than one video input.

Changing parameters

AXIS Camera support is based on MJPEG streaming, and after changing any parameter the connection must be reset.

The simplest way to reset connection is to stop and restart the program.

Aurora Vision Studio support only basic authentication, please check your device setting.
In order to change authentication method you need to right-click device on the list in AXIS Device Manager and go to Configure Device. There you need to change "Authentication Policy" parameter to "Basic"



HTTPS is not supported.

Configuring the settings in the manufacturer's application may take priority.

New camera models use a global rotation setting.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inAddress in AXIS_GrabImage.

See Also

- AXIS_GrabImage – Captures a frame using AXIS.
- AXIS_GrabImage_WithTimeout – Captures with timeout a frame using AXIS.
- AXIS_StartAcquisition – Starts acquisition using AXIS.

AXIS_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures with timeout a frame using AXIS.

Syntax

```
bool avl::AXIS_GrabImage_WithTimeout
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 int inOutputQueueSize,
 int inTimeout,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 atl::Optional<const atl::String&> inStreamProfile,
 atl::Optional<avl::AXISResolution::Type> inResolution,
 atl::Optional<avl::AXISRotation::Type> inRotation,
 atl::Optional<int> inCompression,
 atl::Optional<const atl::String&> inTextString,
 atl::Optional<bool> inUseSquarePixel,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 – 4		ID of camera
	inOutputQueueSize	int	5 – 200		Capacity of output frames queue
	inTimeout	int	1 – ∞	100	Maximum time to wait for frame in milliseconds
	inLogin	Optional<const String&>		NIL	Login for Basic authorization
	inPassword	Optional<const String&>		NIL	Login for Basic authorization
	inStreamProfile	Optional<const String&>		NIL	Profile configuration name.
	inResolution	Optional<AXISResolution::Type>		NIL	Resolution of the returned image
	inRotation	Optional<AXISRotation::Type>		NIL	Rotates the image clockwise
	inCompression	Optional<int>	0 – 100	NIL	Compression level of the image
	inTextString	Optional<const String&>		NIL	
	inUseSquarePixel	Optional<bool>		NIL	Square pixel (aspect ratio) correction
	outImage	Conditional<Image>&			Output image

AXIS_ReadDigitalPortStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads AXIS digital port.

Syntax

```
void avl::AXIS_ReadDigitalPortStatus
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 int inPort,
 bool& outActive
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	AXIS_State&			Object used to maintain state of the function.
→	inAddress	const String&			Source device host or ip address
→	inCameraID	int	1 – 4		ID of camera
→	inLogin	Optional<const String&>		NIL	Login for Basic authorization
→	inPassword	Optional<const String&>		NIL	Login for Basic authorization

←	outActive	bool&			

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inAddress in AXIS_ReadDigitalPortStatus.

AXIS_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts acquisition using AXIS.

Syntax

```
void avl::AXIS_StartAcquisition
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 int inOutputQueueSize,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 atl::Optional<const atl::String&> inStreamProfile,
 atl::Optional<avl::AXISResolution::Type> inResolution,
 atl::Optional<avl::AXISRotation::Type> inRotation,
 atl::Optional<int> inCompression,
 atl::Optional<const atl::String&> inTextString,
 atl::Optional<bool> inUseSquarePixel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 – 4		ID of camera
	inOutputQueueSize	int	5 – 200		Capacity of output frames queue
	inLogin	Optional<const String&>		NIL	Login for Basic authorization

AXIS_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops acquisition using AXIS.

Syntax

```
void avl::AXIS_StopAcquisition
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 – 4		ID of camera

Errors

List of possible exceptions:

Error type	Description
DomainError	Empty inAddress in AXIS_StopAcquisition.

AXIS_WriteDigitalPortStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes AXIS digital port.

Syntax

```
void avl::AXIS_WriteDigitalPortStatus
(
 AXIS_State& ioState,
 const atl::String& inAddress,
 int inCameraID,
 atl::Optional<const atl::String&> inLogin,
 atl::Optional<const atl::String&> inPassword,
 int inPort,
 bool inActive
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	AXIS_State&			Object used to maintain state of the function.
	inAddress	const String&			Source device host or ip address
	inCameraID	int	1 – 4		ID of camera
	inLogin	Optional<const String&>		NIL	Login for Basic authorization
	inPassword	Optional<const String&>		NIL	Login for Basic authorization
	inPort	int	0 – ∞		Port number
	inActive	bool

BitFlow_GetGPOutPin

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets R64 GPOUT pins state.

Syntax

```
void avl::BitFlow_GetGPOutPin
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inOutput,
 bool& outState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	BitFlow_BaseState&			Object used to maintain state of the function.
	inBoardNumber	int			Index of board
	inCameraFileName	const File&			Camera file
	inOutput	int	0 - 6		output
	outState	bool&			pin state

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install BitFlow SDK software. Currently Aurora Vision Studio requires **BitFlow SDK version 6.30**.

BitFlow SDK can be downloaded from following website: http://www.bitflow.com (registration may be required).

Running application

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

This filter uses camera configuration files, which are loaded to register. To load this file to register you should use SysReg application from BitFlow SDK.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- BitFlow_GrabImage - Captures a frame using BitFlow frame grabber.
- BitFlow_GetHardwareTriggerStatus - Gets the status of the hardware trigger.
- BitFlow_SetGPOutPin - Sets R64 GPOUT pins.
- BitFlow_SoftwareTrigger - Performs a software trigger.

BitFlow_GetHardwareTriggerStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the status of the hardware trigger.

Syntax

```
void avl::BitFlow_GetHardwareTriggerStatus
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 avl::BitFlowTriggers::Type inTrigger,
 bool& outTriggerStatus
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file
	inTrigger	BitFlowTriggers::Type		Trigger
	outTriggerStatus	bool&		Status of trigger

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install BitFlow SDK software. Currently Aurora Vision Studio requires **BitFlow SDK version 6.30**.

BitFlow SDK can be downloaded from following website: http://www.bitflow.com (registration may be required).

Running application

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

This filter uses camera configuration files, which are loaded to register. To load this file to register you should use SysReg application from BitFlow SDK.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

BitFlow_GetRegisterName

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a register name.

Syntax

```
void avl::BitFlow_GetRegisterName
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inRegId,
 atl::String& outName
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file
	inRegId	int		Register Id
	outName	String&		Register name

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install BitFlow SDK software. Currently Aurora Vision Studio requires **BitFlow SDK version 6.30**.

BitFlow SDK can be downloaded from following website: http://www.bitflow.com (registration may be required).

Running application

This filter uses camera configuration files, which are loaded to register. To load this file to register you should use SysReg application from BitFlow SDK.

Registers management

Register IDs are declared in "BFTabRegister.h" located in Bitflow SDK. See the corresponding Bitflow Hardware Reference Manual for a description of each bit.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- BitFlow_WriteValueToRegister – Writes a value to a register.
- BitFlow_ReadValueFromRegister – Reads a value from a register.

BitFlow_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using BitFlow frame grabber.

Syntax

```
bool avl::BitFlow_GrabImage
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inInputQueueSize,
 avl::BitFlowTriggerMode::Type inTriggerMode,
 avl::BitFlowTrigAssignments::Type inTriggerAssignments,
 avl::BitFlowTrigPolarity::Type inTriggerAPolarity,
 avl::BitFlowTrigPolarity::Type inTriggerBPolarity,
 avl::Image& outImage,
 atl::int64& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	BitFlow_BaseState&			Object used to maintain state of the function.
→	inBoardNumber	int			Index of board
→	inCameraFileName	const File&			Camera file
→	inInputQueueSize	int	1 – 200	4	Number of incoming frames that can be buffered before the application is able to process them
→	inTriggerMode	BitFlowTriggerMode::Type			Trigger mode of the current camera
→	inTriggerAssignments	BitFlowTrigAssignments::Type			Assign trigger to acquisition engine
→	inTriggerAPolarity	BitFlowTrigPolarity::Type			Polarity for trigger B
→	inTriggerBPolarity	BitFlowTrigPolarity::Type			Polarity for trigger A
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Captured frame ID

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install BitFlow SDK software. Currently Aurora Vision Studio requires **BitFlow SDK version 6.30**.

BitFlow SDK can be downloaded from following website: http://www.bitflow.com (registration may be required).

Running application

This filter uses camera configuration files, which are loaded to register. To load this file to register you should use SysReg application from BitFlow SDK.

Camera identification

To identify the camera, configuration file should be loaded to Aurora Vision Studio, using **inCameraFileName** input. Choosing index of board is too necessary.

Camera file must be located in configuration directory. Default configuration directory should be "C:\BitFlow SDK 5.90\Config". After that, correct directory should be used – it depends on type of board installed in system.

Camera parameters

To change trigger options or digital outputs, use Aurora Vision Studio(see "See also" paragraph). Another parameters might be changed by creating new configuration file. Configuration tool "CamEd" available with BitFlow SDK 5.90 should be used.

Supported pixel formats

- Mono8
- Mono10
- Mono12
- Mono16
- Rgb24
- Rgb30
- Rgb36
- Rgb48

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- BitFlow_GrabImage_WithTimeout – Captures a frame using BitFlow frame grabber.
- BitFlow_GetGPOutPin – Gets R64 GPOUT pins state.
- BitFlow_GetHardwareTriggerStatus – Gets the status of the hardware trigger.

- BitFlow_SoftwareTrigger – Performs a software trigger.

BitFlow_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using BitFlow frame grabber.

Applications: Use this filter if the trigger may be not coming for some time, while the application should be performing other operations continuously (e.g. processing HMI events).

Syntax

```
bool avl::BitFlow_GrabImage_WithTimeout
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inInputQueueSize,
 int inTimeout,
 avl::BitFlowTriggerMode::Type inTriggerMode,
 avl::BitFlowTrigAssignments::Type inTriggerAssignments,
 avl::BitFlowTrigPolarity::Type inTriggerAPolarity,
 avl::BitFlowTrigPolarity::Type inTriggerBPolarity,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<atl::int64>& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	BitFlow_BaseState&			Object used to maintain state of the function.
→	inBoardNumber	int			Index of board
→	inCameraFileName	const File&			Camera file
→	inInputQueueSize	int	1 – 200	4	Number of incoming frames that can be buffered before the application is able to process them
→	inTimeout	int	1 – 3600000	5000	Capture timeout
→	inTriggerMode	BitFlowTriggerMode::Type			Trigger mode of the current camera
→	inTriggerAssignments	BitFlowTrigAssignments::Type			Assign trigger to acquisition engine
→	inTriggerAPolarity	BitFlowTrigPolarity::Type			Polarity for trigger B
→	inTriggerBPolarity	BitFlowTrigPolarity::Type			Polarity for trigger A
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int64>&			Captured frame ID

BitFlow_ReadValueFromRegister

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a value from a register.

Syntax

```
void avl::BitFlow_ReadValueFromRegister
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inRegId,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file
	inRegId	int		Register Id
	outValue	int&		Register value

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install BitFlow SDK software. Currently Aurora Vision Studio requires **BitFlow SDK version 6.30**.

BitFlow SDK can be downloaded from following website: http://www.bitflow.com (registration may be required).

Running application

This filter uses camera configuration files, which are loaded to register. To load this file to register you should use SysReg application from BitFlow SDK.

Registers management

Register IDs are declared in "BFTabRegister.h" located in Bitflow SDK. See the corresponding Bitflow Hardware Reference Manual for a description of each bit.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- BitFlow_WriteValueToRegister – Writes a value to a register.
- BitFlow_GetRegisterName – Gets a register name.

BitFlow_SetGPOutPin

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets R64 GPOUT pins.

Syntax

```
void avl::BitFlow_SetGPOutPin
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inOutput,
 bool inValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	BitFlow_BaseState&			Object used to maintain state of the function.
	inBoardNumber	int			Index of board
	inCameraFileName	const File&			Camera file
	inOutput	int	0 - 6		output
	inValue	bool			pin enabled

Remarks

BitFlow_SoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Performs a software trigger.

Syntax

```
void avl::BitFlow_SoftwareTrigger
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 avl::BitFlowTriggers::Type inTrigger,
 bool inTriggerEnable
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file
	inTrigger	BitFlowTriggers::Type		Trigger to assert
	inTriggerEnable	bool		Trigger enabled / disabled

Remarks

BitFlow_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using BitFlow frame grabber.

Syntax

```
void avl::BitFlow_StartAcquisition
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inInputQueueSize,
 avl::BitFlowTriggerMode::Type inTriggerMode,
 avl::BitFlowTrigAssignments::Type inTriggerAssignments,
 avl::BitFlowTrigPolarity::Type inTriggerAPolarity,
 avl::BitFlowTrigPolarity::Type inTriggerBPolarity
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	BitFlow_BaseState&			Object used to maintain state of the function.
	inBoardNumber	int			Index of board
	inCameraFileName	const File&			Camera file
	inInputQueueSize	int	1 – 200	4	Number of incoming frames that can be buffered before the application is able to process them
	inTriggerMode	BitFlowTriggerMode::Type			Trigger mode of the current camera
	inTriggerAssignments	BitFlowTrigAssignments::Type			Assign trigger to acquisition engine
	inTriggerAPolarity	BitFlowTrigPolarity::Type			Polarity for trigger B
	inTriggerBPolarity	BitFlowTrigPolarity::Type			Polarity for trigger A

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

BitFlow_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using BitFlow frame grabber.

Syntax

```
void avl::BitFlow_StopAcquisition
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

BitFlow_WriteValueToRegister

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes a value to a register.

Syntax

```
void avl::BitFlow_WriteValueToRegister
(
 BitFlow_BaseState& ioState,
 int inBoardNumber,
 const atl::File& inCameraFileName,
 int inRegId,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	BitFlow_BaseState&		Object used to maintain state of the function.
	inBoardNumber	int		Index of board
	inCameraFileName	const File&		Camera file
	inRegId	int		Register Id
	inValue	int		Value to store

Remarks

cxCam_CalibratePointCloud

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Calibrate data channel to point clod output.

Syntax

```
void avl::cxCam_CalibratePointCloud
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const avl::Image& inRangeImage,
 const atl::Optional<atl::File>& inFile,
 const atl::Optional<atl::String>& inCalibrationId,
 atl::Optional<int> inAOI,
 avl::Point3DGrid& outPointCloud
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inRangeImage	const Image&		Data to calibrate.
	inFile	const Optional<File>&	NIL	Calibration file. Leave blank to use the file from device memory.
	inCalibrationId	const Optional<String>&	NIL	Calibration file id.
	inAOI	Optional<int>	NIL	Number of area of interest that you are going to process. Only used to optimize the reading of calibration data.
	outPointCloud	Point3DGrid&		

Remarks

This filter converts the data from the acquisition (typically the third data channel) with a configuration file to return the 3D real coordinate data. For performance reasons, the file is loaded only once, the first time the filter is called for given parameters.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- cxCam_GrabData – Captures a frame using cxCam Support Package.

cxCam_CalibrateZMap

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Calibrate data channel to z-map output.

Syntax

```
void avl::cxCam_CalibrateZMap
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const avl::Image& inRangeImage,
 const atl::Optional<atl::File>& inFile,
 const atl::Optional<atl::String>& inCalibrationId,
 atl::Optional<int> inAOI,
 avl::Surface& outZMap
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inRangeImage	const Image&		Data to calibrate.
	inFile	const Optional<File>&	NIL	Calibration file. Leave blank to use the file from device memory.
	inCalibrationId	const Optional<String>&	NIL	Calibration file id.
	inAOI	Optional<int>	NIL	Number of area of interest that you are going to process. Only used to optimize the reading of calibration data.
	outZMap	Surface&		

Remarks

This filter converts the data from the acquisition (typically the third data channel) with a configuration file to return the 3D real coordinate data. For performance reasons, the file is loaded only once, the first time the filter is called for given parameters.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

cxCam_GetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_GetBoolParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	cxCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device URI
→	inName	const String&		
←	outValue	bool&		

Also in AVL Lite

cxCam_GetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_GetDoubleParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	cxCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device URI
→	inName	const String&		
←	outValue	double&		

Also in AVL Lite

cxCam_GetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_GetEnumParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	cxCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device URI
→	inName	const String&		
←	outValue	String&		

Also in AVL Lite

cxCam_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_GetIntegerParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	cxCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device URI
→	inName	const String&		
←	outValue	int&		

Also in AVL Lite

cxCam_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_GetStringParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	outValue	String&		

Also in AVL Lite

cxCam_GrabData

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using cxCam Support Package.

Syntax

```
bool avl::cxCam_GrabData
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<const avl::CxCamModeAndAlgorithmConfiguration&> inModeAndAlgorithm,
 atl::Optional<const avl::CxCamC6ComponentSelector&> inC6ComponentSelector,
 avl::CxCamImagePixel::Type inPixel,
 avl::CxCamScannerMode::Type inScannerMode,
 avl::CxCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<avl::CxCamTriggerMode::Type> inTriggerMode,
 atl::Optional<avl::CxCamTriggerSequencerMode::Type> inSequencerMode,
 const atl::Array<avl::CxCamC6TriggerSetup>& inC6TriggerSetup,
 atl::Array<avl::CxCamAOIOutput>& outAOI
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	cxCam_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device URI
→	inInputQueueSize	int	3 – 200	4	Capacity of output frames queue
→	inModeAndAlgorithm	Optional<const CxCamModeAndAlgorithmConfiguration&>		NIL	3D algorithm configuration.
→	inC6ComponentSelector	Optional<const CxCamC6ComponentSelector&>		NIL	Component selector for C6 family.
→	inPixel	CxCamImagePixel::Type			Output pixel type.
→	inScannerMode	CxCamScannerMode::Type			Scanner mode.
→	inAcquisitionMode	CxCamAcquisitionMode::Type			AcquisitionMode.
→	inTriggerMode	Optional<CxCamTriggerMode::Type>		NIL	Trigger mode.
→	inSequencerMode	Optional<CxCamTriggerSequencerMode::Type>		NIL	Trigger sequencer mode.
→	inC6TriggerSetup	const Array<CxCamC6TriggerSetup>&			Trigger setup for C6 family.
←	outAOI	Array<CxCamAOIOutput>&			Output data. Usually one item.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install AT SolutionPackage Software (previously known as cxCam Support Package) with camera dedicated drivers.

Package can be downloaded from the following website: https://www.at-sensors.com/ps/downloads/ (registration may be required).

It may also be required to install GigE Vision Transport Layer as described here.

Add DLL path to system environment variable may be required. The SDK is divided into several directories with shared libraries – you have to add them all.

You should install the transport layer from Common Vision Box Runtime. The lack of this component may cause the application to behave unexpectedly.

Installing special network transport transport layer from vendor may be required.

Recommended AT SolutionPackage Software version for Aurora Vision Studio usage is **2025.2.1**.

32-bit platform is not supported.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **URI** – should be specified on device casing.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- cxCam_StartAcquisition – Initializes and starts image acquisition in a camera.

cxCam_GrabData_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using cxCam Support Package with timeout.

Syntax

```
bool avl::cxCam_GrabData_WithTimeout
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 int inTimeout,
 atl::Optional<const avl::CxCamModeAndAlgorithmConfiguration&> inModeAndAlgorithm,
 atl::Optional<const avl::CxCamC6ComponentSelector&> inC6ComponentSelector,
 avl::CxCamImagePixel::Type inPixel,
 avl::CxCamScannerMode::Type inScannerMode,
 avl::CxCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<avl::CxCamTriggerMode::Type> inTriggerMode,
 atl::Optional<avl::CxCamTriggerSequencerMode::Type> inSequencerMode,
 const atl::Array<avl::CxCamC6TriggerSetup>& inC6TriggerSetup,
 atl::Conditional<atl::Array<avl::CxCamAOIOutput>>& outAOI
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	cxCam_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device URI.
→	inInputQueueSize	int	3 – 200	4	Capacity of output frames queue
→	inTimeout	int	1 – ∞	100	Maximum time to wait for frame in milliseconds.
→	inModeAndAlgorithm	Optional<const CxCamModeAndAlgorithmConfiguration&>		NIL	3D algorithm configuration.
→	inC6ComponentSelector	Optional<const CxCamC6ComponentSelector&>		NIL	Component selector for C6 family.
→	inPixel	CxCamImagePixel::Type			Output pixel type.
→	inScannerMode	CxCamScannerMode::Type			Scanner mode.
→	inAcquisitionMode	CxCamAcquisitionMode::Type			AcquisitionMode.
→	inTriggerMode	Optional<CxCamTriggerMode::Type>		NIL	Trigger mode.
→	inSequencerMode	Optional<CxCamTriggerSequencerMode::Type>		NIL	Trigger sequencer mode.
→	inC6TriggerSetup	const Array<CxCamC6TriggerSetup>&			Trigger setup for C6 family.
←	outAOI	Conditional<Array<CxCamAOIOutput>>&			Output data. Usually one item.

cxCam_SetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_SetBoolParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	inValue	bool		

Also in AVL Lite

cxCam_SetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_SetDoubleParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	inValue	double		

Also in AVL Lite

cxCam_SetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_SetEnumParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	inValue	const String&		

Also in AVL Lite

cxCam_SetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_SetIntegerParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	inValue	int		

Also in AVL Lite

cxCam_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter using cxCam Support Package.

Syntax

```
void avl::cxCam_SetStringParameter
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI
	inName	const String&		
	inValue	const String&		

Also in AVL Lite

cxCam_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::cxCam_StartAcquisition
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<const avl::CxCamModeAndAlgorithmConfiguration&> inModeAndAlgorithm,
 atl::Optional<const avl::CxCamC6ComponentSelector&> inC6ComponentSelector,
 avl::CxCamImagePixel::Type inPixel,
 avl::CxCamScannerMode::Type inScannerMode,
 avl::CxCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<avl::CxCamTriggerMode::Type> inTriggerMode,
 atl::Optional<avl::CxCamTriggerSequencerMode::Type> inSequencerMode,
 const atl::Array<avl::CxCamC6TriggerSetup>& inC6TriggerSetup
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	cxCam_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device URI
	inInputQueueSize	int	3 – 200	4	Capacity of output frames queue
	inModeAndAlgorithm	Optional<const CxCamModeAndAlgorithmConfiguration&>		NIL	3D algorithm configuration.
	inC6ComponentSelector	Optional<const CxCamC6ComponentSelector&>		NIL	Component selector for C6 family.
	inPixel	CxCamImagePixel::Type			Output pixel type.
	inScannerMode	CxCamScannerMode::Type			Scanner mode.
	inAcquisitionMode	CxCamAcquisitionMode::Type			AcquisitionMode.
	inTriggerMode	Optional<CxCamTriggerMode::Type>		NIL	Trigger mode.
	inSequencerMode	Optional<CxCamTriggerSequencerMode::Type>		NIL	Trigger sequencer mode.
	inC6TriggerSetup	const Array<CxCamC6TriggerSetup>&			Trigger setup for C6 family.

Remarks

This filter is intended for establishing connection with a Automation Technology 3D camera device using cxCam Packager interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of cxCam_GrabData or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. cxCam_GrabData or cxCam_GrabData_WithTimeout filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install AT SolutionPackage Software (previously known as cxCam Support Package) with camera dedicated drivers.

Package can be downloaded from the following website: https://www.at-sensors.com/ps/downloads/ (registration may be required).

It may also be required to install GigE Vision Transport Layer as described here.

Add DLL path to system environment variable may be required. The SDK is divided into several directories with shared libraries - you have to add them all.

You should install the transport layer from Common Vision Box Runtime. The lack of this component may cause the application to behave unexpectedly.

Installing special network transport transport layer from vendor may be required.

Recommended AT SolutionPackage Software version for Aurora Vision Studio usage is **2025.2.1**.

32-bit platform is not supported.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **URI** - should be specified on device casing.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

cxCam_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::cxCam_StopAcquisition
(
 cxCam_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	cxCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device URI

Dahua_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::Dahua_GenerateSoftwareTrigger
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Dahua_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Dahua_GetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool.

Syntax

```
void avl::Dahua_GetBoolParameter
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Dahua_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	bool&		Value retrieved from device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Dahua_GetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Double.

Syntax

```
void avl::Dahua_GetDoubleParameter
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	Dahua_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying number
→	inParameter	const String&		Name of parameter
←	outValue	double&		Value retrieved from device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Dahua_GetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enum.

Syntax

```
void avl::Dahua_GetEnumParameter
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::String& outValue,
 atl::Array<atl::String>& outValuesList
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	Dahua_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying number
→	inParameter	const String&		Name of parameter
←	outValue	String&		Value retrieved from device
←	outValuesList	Array<String>&		List of possible values

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Dahua_GetIntParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::Dahua_GetIntParameter
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Dahua_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	int&		Value retrieved from device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Dahua_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::Dahua_GetStringParameter
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Dahua_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	String&		Value retrieved from device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Dahua_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Dahua.

Syntax

```
bool avl::Dahua_GrabImage
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<float> inFrameRate,
 atl::Optional<float> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<int> inBlackLevel,
 atl::Optional<bool> inTriggerEnabled,
 atl::Optional<avl::DahuaTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::DahuaTriggerActivation::Type> inTriggerActivation,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Dahua_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inInputQueueSize	int	0 – 200	4	Capacity of output frames queue
→	inFrameRate	Optional<float>		NIL	Requested camera frame rate in frames per second
→	inExposureTime	Optional<float>		NIL	Camera frame exposition time
→	inGain	Optional<float>		NIL	Analog gain of source image in device raw unit
→	inBlackLevel	Optional<int>		NIL	Black level of source image
→	inTriggerEnabled	Optional<bool>		NIL	Configure trigger enable
→	inTriggerSource	Optional<DahuaTriggerSource::Type>		NIL	Source of acquisition trigger
→	inTriggerActivation	Optional<DahuaTriggerActivation::Type>		NIL	Circumstances defining when the trigger is activated
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Captured frame ID
←	outTimestamp	int64&			Captured frame timestamp

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install MVViewer software with camera dedicated drivers.

MVViewer can be downloaded from the following website: https://www.dahuasecurity.com/ (registration may be required).

Add DLL path to system environment variable may be required.

Recommended MVViewer version for Aurora Vision Studio usage is **2.1.6**.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – should be specified on device casing in format **"vendor:serial number"**.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Dahua_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	const String&		Value to set

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Dahua_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::Dahua_StartAcquisition
(
 Dahua_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<float> inFrameRate,
 atl::Optional<float> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<int> inBlackLevel,
 atl::Optional<bool> inTriggerEnabled,
 atl::Optional<avl::DahuaTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::DahuaTriggerActivation::Type> inTriggerActivation
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Dahua_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inFrameRate	Optional<float>		NIL	Requested camera frame rate in frames per second
	inExposureTime	Optional<float>		NIL	Camera frame exposition time
	inGain	Optional<float>		NIL	Analog gain of source image in device raw unit
	inBlackLevel	Optional<int>		NIL	Black level of source image
	inTriggerEnabled	Optional<bool>		NIL	Configure trigger enable
	inTriggerSource	Optional<DahuaTriggerSource::Type>		NIL	Source of acquisition trigger
	inTriggerActivation	Optional<DahuaTriggerActivation::Type>		NIL	Circumstances defining when the trigger is activated

Remarks

This filter is intended for establishing connection with a Dahua camera device using MVViewer interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of Dahua_GrabImage or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. Dahua_GrabImage or Dahua_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install MVViewer software with camera dedicated drivers.

MVViewer can be downloaded from the following website: https://www.dahuasecurity.com/ (registration may be required).

Add DLL path to system environment variable may be required.

Recommended MVViewer version for Aurora Vision Studio usage is **2.1.6**.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – should be specified on device casing in format **"vendor:serial number"**.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

DAQmx_ConfigureTiming

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configure timing in specified task.

Syntax

```
void avl::DAQmx_ConfigureTiming
(
 DAQmx_ConfigureTimingState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 avl::TimingMode::Type inTimingMode,
 atl::Optional<const atl::String&> inSource,
 float inRate,
 avl::DAQmxActiveEdge::Type inActiveEdge,
 avl::DAQmxSampleMode::Type inSampleMode,
 int inSampsPerChanToAcq,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_ConfigureTimingState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
→	inTaskID	DAQmxTaskID		ID of task where timing is used
→	inTimingMode	TimingMode::Type		Mode of the timing
→	inSource	Optional<const String&>	NIL	Source terminal of sample clock
→	inRate	float		Sampling rate in samples per second
→	inActiveEdge	DAQmxActiveEdge::Type		Active edge to generate or acquire samples
→	inSampleMode	DAQmxSampleMode::Type		Sampling mode
→	inSampsPerChanToAcq	int		Number of samples to acquire or generate for each channel
←	outTaskID	Conditional<DAQmxTaskID>&		ID of a created task

Remarks

Device driver software

This filter is intended to cooperate with digital I/O cards using its vendor driver software. To be able to connect to a card it is required to install NI-DAQmx driver software. Currently Aurora Vision Studio requires **NI-DAQmx version 25.0**.

NI-DAQmx driver software can be downloaded from the following website: https://www.ni.com/pl-pl/support/downloads/drivers/download.ni-daq-mx.html#480879.

Device identification

When there is only one device connected to computer, **inDeviceID** field can be set to Auto. In this situation first available device will be found and connected.

inDeviceID can be used to pick one of multiple devices connected to computer. Set this field to Device alias (for example "Dev1"), product name or serial number. This parameters should be available in Measurement & Automation Explorer.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- DAQmx_ConfigDigitEdgeTrigger – Configures a trigger in a specified task.
- DAQmx_ConfigAnalogEdgeTrigger – Returns values from a digital channel.

DAQmx_CreateAnalogChannel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Creates a task and channel to measure or generate analog values.

Syntax

```
void avl::DAQmx_CreateAnalogChannel
(
 DAQmx_CreateAnalogChannelState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<const atl::String&> inChannel,
 avl::ElectricalMode::Type inCVType,
 avl::DirectionMode::Type inIOType,
 avl::DAQmxTerminalConfig::Type inTerminalConfig,
 float inMinValue,
 float inMaxValue,
 avl::DAQmxShuntResistorLoc::Type inShuntResistorLocation,
 atl::Optional<float> inExtShuntResistorValue,
 avl::DAQmxTaskID& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_CreateAnalogChannelState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or serial number
→	inChannel	Optional<const String&>	NIL	Name of the physical channel used to create a virtual channel
→	inCVType	ElectricalMode::Type		Electrical mode
→	inIOType	DirectionMode::Type		Direction of channel
→	inTerminalConfig	DAQmxTerminalConfig::Type		Input terminal configuration
→	inMinValue	float		Minimum value, that is expected to measure or generate
→	inMaxValue	float	5.0f	Maximum value, that is expected to measure or generate
→	inShuntResistorLocation	DAQmxShuntResistorLoc::Type		Location of the shunt resistor
→	inExtShuntResistorValue	Optional<float>	NIL	Value of the shunt resistor
←	outTaskID	DAQmxTaskID&		ID of a created task

DAQmx_CreateCountEdgesChannel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Creates a task and channel to count number of edges.

Syntax

```
void avl::DAQmx_CreateCountEdgesChannel
(
 DAQmx_CreateCountEdgesChannelState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::Optional<const atl::String&> inCounter,
 avl::DAQmxActiveEdge::Type inActiveEdge,
 int inInitialCount,
 avl::DAQmxCountDirection::Type inCountDirection,
 avl::DAQmxTaskID& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_CreateCountEdgesChannelState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or serial number
→	inCounter	const Optional<const String&>	NIL	Name of a counter used to create virtual channel
→	inActiveEdge	DAQmxActiveEdge::Type		Active edge for counting
→	inInitialCount	int		Initial value
→	inCountDirection	DAQmxCountDirection::Type		Type of counting (incrementing and decrementing values)
←	outTaskID	DAQmxTaskID&		ID of a created task

DAQmx_CreateDigitalPort

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Creates a task and channel to measure or generate digital values.

Syntax

```
void avl::DAQmx_CreateDigitalPort
(
 DAQmx_CreateDigitalPortState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::Optional<const atl::String&> inPort,
 avl::DirectionMode::Type inIOType,
 atl::Optional<int> inFirstLine,
 atl::Optional<int> inLastLine,
 avl::DAQmxTaskID& outTaskID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQmx_CreateDigitalPortState&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device alias, product name or serial number
	inPort	const Optional<const String&>		NIL	Name of a physical port used to create a virtual channel
	inIOType	DirectionMode::Type			Direction of a channel
	inFirstLine	Optional<int>	0 – ∞	NIL	First line to measure or generate
	inLastLine	Optional<int>	0 – ∞	NIL	Last line to measure or generate
	outTaskID	DAQmxTaskID&			ID of a created task

DAQmx_CreatePulseChannelFreq

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Creates a task and channel to generate pulse.

Syntax

```
void avl::DAQmx_CreatePulseChannelFreq
(
 DAQmx_CreatePulseChannelFreqState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<const atl::String&> inCounter,
 avl::DAQmxIdleState::Type inIdleState,
 float inInitDelay,
 float inFrequency,
 float inDutyCycle,
 avl::DAQmxTaskID& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_CreatePulseChannelFreqState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
→	inCounter	Optional<const String&>	NIL	Name of a counter used to create virtual channel
→	inIdleState	DAQmxIdleState::Type		Resting state of an output terminal
→	inInitDelay	float		Time (in seconds) to wait before generating pulse
→	inFrequency	float		Frequency of generated pulse
→	inDutyCycle	float		The width of the pulse divided by the pulse period
←	outTaskID	DAQmxTaskID&		ID of a created task

DAQmx_GetDigitalChannel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns array of values from a digital channels.

Syntax

```
void avl::DAQmx_GetDigitalChannel
(
 DAQmx_GetDigitalChannelState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 atl::Optional<int> inTimeout,
 atl::Array<bool>& outValues,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQmx_GetDigitalChannelState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
	inTaskID	DAQmxTaskID		ID of task to read sample from
	inTimeout	Optional<int>	NIL	Time (in milliseconds) to wait for the function to get sample
	outValues	Array<bool>&		Digital values read from task
	outTaskID	Conditional<DAQmxTaskID>&		ID of a created task

See Also

- DAQmx_SetDigitalChannel – Sets array of values to a digital channels.

DAQmx_ReadAnalogArray

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads multiple samples from a specified analog task.

Syntax

```
void avl::DAQmx_ReadAnalogArray
(
 DAQmx_ReadAnalogArrayState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 int inSamples,
 atl::Optional<int> inTimeout,
 atl::Array<float>& outValues,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	DAQmx_ReadAnalogArrayState&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device alias, product name or a serial number
	inTaskID	DAQmxTaskID			ID of task to read samples from
	inSamples	int	1 – ∞		Number of samples to read
	inTimeout	Optional<int>		NIL	Time (in milliseconds) to wait for the function to read samples
	outValues	Array<float>&			Array of read values
	outTaskID	Conditional<DAQmxTaskID>&			ID of a created task

DAQmx_ReadAnalogScalar

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a sample from a specified analog task.

Syntax

```
void avl::DAQmx_ReadAnalogScalar
(
 DAQmx_ReadAnalogScalarState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 atl::Optional<int> inTimeout,
 float& outValue,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_ReadAnalogScalarState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
→	inTaskID	DAQmxTaskID		ID of task to read sample from
→	inTimeout	Optional<int>	NIL	Time (in milliseconds) to wait for the function to read sample

DAQmx_ResetDevice

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets a selected device.

Syntax

```
void avl::DAQmx_ResetDevice
(
 DAQmx_ResetDeviceState& ioState,
 const atl::String& inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQmx_ResetDeviceState&		Object used to maintain state of the function.
	inDeviceID	const String&		Device alias, product name or a serial number

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

DAQmx_SetDigitalChannel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets array of values to a digital channels.

Syntax

```
void avl::DAQmx_SetDigitalChannel
(
 DAQmx_SetDigitalChannelState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 atl::Optional<int> inTimeout,
 const atl::Array<bool>& inValues,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_SetDigitalChannelState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
→	inTaskID	DAQmxTaskID		ID of task to write sample to
→	inTimeout	Optional<int>	NIL	Time (in milliseconds) to wait for the function to set sample
→	inValues	const Array<bool>&		Values to write to channel
←	outTaskID	Conditional<DAQmxTaskID>&		ID of a created task

Remarks

Device driver software

This filter is intended to cooperate with digital I/O cards using its vendor driver software. To be able to connect to a card it is required to install NI-DAQmx driver software. Currently Aurora Vision Studio requires **NI-DAQmx version 25.0**.

NI-DAQmx driver software can be downloaded from the following website: https://www.ni.com/pl-pl/support/downloads/drivers/download.ni-daq-mx.html#480879.

Device identification

When there is only one device connected to computer, **inDeviceID** field can be set to Auto. In this situation first available device will be found and connected.

inDeviceID can be used to pick one of multiple devices connected to computer. Set this field to Device alias (for example "Dev1"), product name or serial number. This parameters should be available in Measurement & Automation Explorer.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- DAQmx_GetDigitalChannel – Returns array of values from a digital channels.

DAQmx_StartTask

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts a specified task.

Syntax

```
void avl::DAQmx_StartTask
(
 DAQmx_StartTaskState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQmx_StartTaskState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device alias, product name or serial number
	inTaskID	DAQmxTaskID		ID of a task to start

Remarks

Device driver software

This filter is intended to cooperate with digital I/O cards using its vendor driver software. To be able to connect to a card it is required to install NI-DAQmx driver software. Currently Aurora Vision Studio requires **NI-DAQmx version 25.0**.

- DAQmx_StopTask – Stops and clears a task.

DAQmx_StopTask

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops and clears a task.

Syntax

```
void avl::DAQmx_StopTask
(
 DAQmx_StopTaskState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQmx_StopTaskState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device alias, product name or serial number
	inTaskID	DAQmxTaskID		ID of a task to stop

- DAQmx_StartTask – Starts a specified task.

DAQmx_WriteAnalogArray

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes multiple samples to a specified analog task.

Syntax

```
void avl::DAQmx_WriteAnalogArray
(
 DAQmx_WriteDigitalArrayState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 atl::Optional<int> inTimeout,
 const atl::Array<float>& inValues,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
	ioState	DAQmx_WriteDigitalArrayState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
	inTaskID	DAQmxTaskID		ID of task to write samples to
	inTimeout	Optional<int>	NIL	Time (in milliseconds) to wait for the function to write samples
	inValues	const Array<float>&		Array of samples to write
	outTaskID	Conditional<DAQmxTaskID>&		ID of a created task

DAQmx_WriteAnalogScalar

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an analog input to a specified value.

Syntax

```
void avl::DAQmx_WriteAnalogScalar
(
 DAQmx_WriteAnalogScalarState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::DAQmxTaskID inTaskID,
 atl::Optional<int> inTimeout,
 float inValue,
 atl::Conditional<avl::DAQmxTaskID>& outTaskID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	DAQmx_WriteAnalogScalarState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device alias, product name or a serial number
→	inTaskID	DAQmxTaskID		ID of task to write samples to
→	inTimeout	Optional<int>	NIL	Time (in milliseconds) to wait for the function to write sample

Ensenso_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Triggers software trigger.

Syntax

```
void avl::Ensenso_GenerateSoftwareTrigger
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- Ensenso_StartAcquisition – Starts capturing data from an Ensenso camera.

Ensenso_GetGlobalParameter_Bool

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get the value of a bool parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_Bool
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	bool&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Will throw atl::DomainError if the type does not exist or is null

Ensenso_GetGlobalParameter_BoolOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get the value of a bool parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_BoolOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 atl::Conditional<bool>& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	Conditional<bool>&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetGlobalParameter_Double

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a double parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_Double
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
⇆	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inPath	const String&		Configuration path, relative.
←	outValue	double&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Will throw atl::DomainError if the type does not exist or is null

Ensenso_GetGlobalParameter_DoubleOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a double parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_DoubleOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 atl::Conditional<double>& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inPath	const String&		Configuration path, relative.
	outValue	Conditional<double>&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetGlobalParameter_Int

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get the value of an int parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_Int
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
⇄	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inPath	const String&		Configuration path, relative.
←	outValue	int&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Will throw atl::DomainError if the type is not convertible to requested type

Will throw atl::DomainError if the type does not exist or is null

Ensenso_GetGlobalParameter_IntOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of an int parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_IntOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 atl::Conditional<int>& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inPath	const String&		Configuration path, relative.
←	outValue	Conditional<int>&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetGlobalParameter_String

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a string parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_String
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
⇆	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inPath	const String&		Configuration path, relative.
←	outValue	String&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Will throw atl::DomainError if the type does not exist or is null

Ensenso_GetGlobalParameter_StringOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a string parameter.

Syntax

```
void avl::Ensenso_GetGlobalParameter_StringOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 atl::Conditional<atl::String>& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inPath	const String&		Configuration path, relative.
←	outValue	Conditional<String>&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetParameter_Bool

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a bool parameter.s

Syntax

```
void avl::Ensenso_GetParameter_Bool
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	bool&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Ensenso_GetParameter_BoolOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a bool parameter.s

Syntax

```
void avl::Ensenso_GetParameter_BoolOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 atl::Conditional<bool>& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	Conditional<bool>&		

Examples

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetParameter_Double

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a double parameter.

Syntax

```
void avl::Ensenso_GetParameter_Double
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	double&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

Ensenso_GetParameter_DoubleOrNil

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of a double parameter.

Syntax

```
void avl::Ensenso_GetParameter_DoubleOrNil
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 atl::Conditional<double>& outValue
)
```

Parameters

	Name	Type	Default	Description
↻	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	Conditional<double>&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Errors

Will throw atl::DomainError if the type is not convertible to requested type

Ensenso_GetParameter_Int

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the value of an int parameter.

Syntax

```
void avl::Ensenso_GetParameter_Int
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
→	inPath	const String&		Configuration path, relative.
←	outValue	int&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Also in AVL Lite

Ensenso_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Images using Ensenso.

Syntax

```
bool avl::Ensenso_GrabImage
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 avl::Image& outImage1,
 atl::Conditional<avl::Image>& outImage2
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inParametersFile	const Optional<File>&	NIL	Initial global parameters.
←	outImage1	Image&		Image from the left camera of a dual camera sensor or the only image from a single camera sensor.
←	outImage2	Conditional<Image>&		Image from the right camera of a dual camera sensor if exists.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button
- From NxTreeEdit application
  - Either:
    - Launch Aurora Vision Studio, add Ensenso_GrabPoint3DGrid filter, Run it
    - Launch NxView, open camera
  - Launch NxTreeEdit, connect to wanted instance
  - Adjust settings as wanted, either in NxView or NxTreeEdit
  - right click on */Cameras/BySerialNo/WantedSerialNumber* and select *Copy value as JSON string*
  - save to a simple text file using an editor

The settings include all camera parameters, including *Link*, *Calibration* and *Parameters* The saved file can be then used in *inCalibrationFile* and *inSettingsFile* arguments.

To obtain global parameters, follow previous NxTreeEdit step, but save the global */Parameters* node.

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Images using Ensenso.

Syntax

```
bool avl::Ensenso_GrabImage_WithTimeout
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 int inTimeout,
 atl::Conditional<avl::Image>& outImage1,
 atl::Conditional<avl::Image>& outImage2
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Ensenso_State&			Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&			Structures identifying devices.
	inParametersFile	const Optional<File>&		NIL	Initial global parameters.
	inTimeout	int	100 - 3600000	5000	Maximum time to wait for frame in milliseconds.
	outImage1	Conditional<Image>&			Image from the left camera of a dual camera sensor or the only image from a single camera sensor.
	outImage2	Conditional<Image>&			Image from the right camera of a dual camera sensor if exists.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)

Ensenso_GrabPoint3DGrid

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a Point3DGrid using Ensenso.

Syntax

```
bool avl::Ensenso_GrabPoint3DGrid
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 avl::Point3DGrid& outGrid
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inParametersFile	const Optional<File>&	NIL	Initial global parameters.
←	outGrid	Point3DGrid&		Captured Grid.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button
- From NxTreeEdit application
  - Either:
    - Launch Aurora Vision Studio, add Ensenso_GrabPoint3DGrid filter, Run it
    - Launch NxView, open camera
  - Launch NxTreeEdit, connect to wanted instance
  - Adjust settings as wanted, either in NxView or NxTreeEdit
  - right click on */Cameras/BySerialNo/WantedSerialNumber* and select *Copy value as JSON string*
  - save to a simple text file using an editor

The settings include all camera parameters, including *Link*, *Calibration* and *Parameters* The saved file can be then used in *inCalibrationFile* and *inSettingsFile* arguments.

To obtain global parameters, follow previous NxTreeEdit step, but save the global */Parameters* node.

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_GrabPoint3DGrid_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a Point3DGrid using Ensenso.

Syntax

```
bool avl::Ensenso_GrabPoint3DGrid_WithTimeout
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 int inTimeout,
 const atl::Optional<atl::File>& inParametersFile,
 atl::Conditional<avl::Point3DGrid>& outGrid
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Ensenso_State&			Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&			Structures identifying devices.
	inTimeout	int	100 – 3600000	5000	Maximum time to wait for frame in milliseconds.
	inParametersFile	const Optional<File>&		NIL	Initial global parameters.
	outGrid	Conditional<Point3DGrid>&			Captured Grid.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button
- From NxTreeEdit application
  - Either:
    - Launch Aurora Vision Studio, add Ensenso_GrabPoint3DGrid filter, Run it
    - Launch NxView, open camera
  - Launch NxTreeEdit, connect to wanted instance
  - Adjust settings as wanted, either in NxView or NxTreeEdit
  - right click on */Cameras/BySerialNo/WantedSerialNumber* and select *Copy value as JSON string*
  - save to a simple text file using an editor

The settings include all camera parameters, including *Link*, *Calibration* and *Parameters* The saved file can be then used in *inCalibrationFile* and *inSettingsFile* arguments.

To obtain global parameters, follow previous NxTreeEdit step, but save the global */Parameters* node.

Ensenso_GrabPointMapTexture

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a Point Map Texture using Ensenso.

Syntax

```
bool avl::Ensenso_GrabPointMapTexture
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 avl::Image& outTexture
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inParametersFile	const Optional<File>&	NIL	Initial global parameters.
←	outTexture	Image&		Captured texture.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button

Also in AVL Lite

Ensenso_GrabSurface

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a Surface using Ensenso.

Syntax

```
bool avl::Ensenso_GrabSurface
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 avl::Surface& outSurface
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Ensenso_State&		Object used to maintain state of the function.
→	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
→	inParametersFile	const Optional<File>&	NIL	Initial global parameters.
←	outSurface	Surface&		Captured Surface.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button
- From NxTreeEdit application
  - Either:
    - Launch Aurora Vision Studio, add Ensenso_GrabPoint3DGrid filter, Run it
    - Launch NxView, open camera
  - Launch NxTreeEdit, connect to wanted instance
  - Adjust settings as wanted, either in NxView or NxTreeEdit
  - right click on */Cameras/BySerialNo/WantedSerialNumber* and select *Copy value as JSON string*
  - save to a simple text file using an editor

The settings include all camera parameters, including *Link*, *Calibration* and *Parameters* The saved file can be then used in *inCalibrationFile* and *inSettingsFile* arguments.

To obtain global parameters, follow previous NxTreeEdit step, but save the global */Parameters* node.

Surface, Point3DGrid, Point color map

If one properly sets the global */Parameters/RenderPointMap* settings node (e.g. by using inParametersFile parameter) output data will change.

- To obtain Surface, RenderPointMap should contain ViewPose node, Point3DGrid will be outputted (perspective projection from camera).
- To obtain Point3DGrid, do not set the ViewPose parameter, and use only one stereoscopic camera
- To obtain Images one has to use Surface output, and make sure RenderPointMap/Texture is set to true

Currently only RenderPointMap node is applied from global Parameters. Other settings may be applied in future revisions.

Mixing Grab filters

Data internally is processed in frames. A frame can contain Surface, Image and Point3DGrid at the same time, or any mix of them. Grab filters will take proper data from current frame, if no data is available in current frame it is discarded, and next frame is taken. This process is repeated until data is available or the filter times out.

If one configures camera to grab a Surface and an Image, a frame will contain Surface and an Image, no Point3DGrid. When one uses GrabPoint3DGrid in that situation it will never output data, because no frame contains a Point3DGrid. Two consecutive GrabSurface will discard one Image. Second Grab surface finds no Surface in current frame - it was processed, it will discard it and look in the next frame.

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_LoadSettings

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Loads parameter data from a file.

Syntax

```
void avl::Ensenso_LoadSettings
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation>& inDevice,
 const atl::File& inSettingsFile
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inDevice	const Optional<EnsensoCameraInformation>&	NIL	Specific device.
	inSettingsFile	const File&		JSON encoded parameters for camera.

Description

Loads *Parameters* node from settings file.

Remarks

Settings

To obtain settings from the camera:

- From NxView Parameters window
  - Launch NxView
  - Open camera
  - Open Parameters window (menu Capture->Parameters...)
  - Adjust settings as wanted
  - Use *Save...* button
- From NxTreeEdit application
  - Either:
    - Launch Aurora Vision Studio, add Ensenso_GrabPoint3DGrid filter, Run it
    - Launch NxView, open camera
  - Launch NxTreeEdit, connect to wanted instance
  - Adjust settings as wanted, either in NxView or NxTreeEdit
  - right click on */Cameras/BySerialNo/WantedSerialNumber* and select *Copy value as JSON string*
  - save to a simple text file using an editor

The settings include all camera parameters, including *Link*, *Calibration* and *Parameters* The saved file can be then used in *inCalibrationFile* and *inSettingsFile* arguments.

Also in AVL Lite

Ensenso_SetGlobalParameter_Bool

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a bool parameter.

Syntax

```
void avl::Ensenso_SetGlobalParameter_Bool
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 const bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inPath	const String&		Configuration path, relative.
	inValue	const bool		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetGlobalParameter_Double

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a double parameter.

Syntax

```
void avl::Ensenso_SetGlobalParameter_Double
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 const double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inPath	const String&		Configuration path, relative.
	inValue	const double		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetGlobalParameter_Int

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an int parameter.

Syntax

```
void avl::Ensenso_SetGlobalParameter_Int
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 const int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inPath	const String&		Configuration path, relative.
	inValue	const int		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetGlobalParameter_String

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a string parameter.

Syntax

```
void avl::Ensenso_SetGlobalParameter_String
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::String& inPath,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inPath	const String&		Configuration path, relative.
	inValue	const String&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetParameter_Bool

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a bool parameter.

Syntax

```
void avl::Ensenso_SetParameter_Bool
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 const bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
	inPath	const String&		Configuration path, relative.
	inValue	const bool		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetParameter_Double

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a double parameter.

Syntax

```
void avl::Ensenso_SetParameter_Double
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 const double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
	inPath	const String&		Configuration path, relative.
	inValue	const double		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetParameter_Int

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an int parameter.

Syntax

```
void avl::Ensenso_SetParameter_Int
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 const int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
	inPath	const String&		Configuration path, relative.
	inValue	const int		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_SetParameter_String

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a string parameter.

Syntax

```
void avl::Ensenso_SetParameter_String
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<avl::EnsensoCameraInformation> inDevice,
 const atl::String& inPath,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inDevice	const Optional<EnsensoCameraInformation>	NIL	Specific device.
	inPath	const String&		Configuration path, relative.
	inValue	const String&		

Examples

Configuration tree

for example path Sensor/Temperature in GetGlobalParamerter filter will give read only access to currently opened camera sensor temperature (double)

Configuration paths are relative to root or camera tree.

path Parameters/Capture/PixelClock in GetParamerter filter will give access to camera pixel clock

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso SDK and uEye driver can be downloaded from the following websites: https://community.ensenso.com/t/ensenso-sdk-downloads/ and https://en.ids-imaging.com/downloads.html?choice=ueye

Recommended Ensenso SDK version for Aurora Vision Studio usage is **4.0.1502** and uEye driver **4.96.1**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Ensenso_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts capturing data from an Ensenso camera.

Applications: Typically used for establishing camera connectivity before the first trigger event. Especially important for multiple-camera systems.

Syntax

```
void avl::Ensenso_StartAcquisition
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices,
 const atl::Optional<atl::File>& inParametersFile,
 const bool inSoftwareTriggered
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.
	inParametersFile	const Optional<File>&	NIL	Initial global parameters.
	inSoftwareTriggered	const bool	False	When true, capture will wait for GenerateSoftwareTrigger.

Remarks

Initial parameters

Initial parameters are only set during capture start. To change parameters either restart the stream, or use appropriate Set/Get filters.

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Ensenso SDK software, and uEye driver (same as in IDS camera filters)

Ensenso_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops data acquisition in a Ensenso device.

Syntax

```
void avl::Ensenso_StopAcquisition
(
 Ensenso_State& ioState,
 const atl::Array<avl::EnsensoCameraInformation>& inDevices
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ensenso_State&		Object used to maintain state of the function.
	inDevices	const Array<EnsensoCameraInformation>&		Structures identifying devices.

Remarks

Camera identification

When there is only one Ensenso camera connected, the field **inDevices** can be set to Auto. In this situation, the first available camera will be used.

inDevices can be used to pick one or many of multiple cameras connected to the computer.

Also in AVL Lite

FlyCapture_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::FlyCapture_GenerateSoftwareTrigger
(
 FlyCapture_State& ioState,
 atl::Optional<int> inDeviceSerialNumber
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	FlyCapture_State&		Object used to maintain state of the function.
→	inDeviceSerialNumber	Optional<int>	NIL	Source device serial number

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

FlyCapture_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Flir camera.

Syntax

```
bool avl::FlyCapture_GrabImage
(
 FlyCapture_State& ioState,
 atl::Optional<int> inDeviceSerialNumber,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<float> inShutter,
 atl::Optional<float> inGain,
 atl::Optional<float> inExposure,
 atl::Optional<float> inFrameRate,
 avl::FlirTriggerMode::Type inTriggerMode,
 avl::FlirColorMode::Type inColorMode,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	FlyCapture_State&			Object used to maintain state of the function.
→	inDeviceSerialNumber	Optional<int>		NIL	Source device serial number
→	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
→	inShutter	Optional<float>	0.0 – ∞	NIL	Shutter time
→	inGain	Optional<float>	0.0 – ∞	NIL	Image analog gain value
→	inExposure	Optional<float>		NIL	Exposure time
→	inFrameRate	Optional<float>	0.1 – ∞	NIL	Requested camera frame rate
→	inTriggerMode	FlirTriggerMode::Type			Camera trigger mode and source control
→	inColorMode	FlirColorMode::Type			Requested grayscale or color mode of output image
←	outImage	Image&			Output image

Getting Started

This application note provides information on how to install, configure, and use Point Grey imaging cameras with Aurora Vision software: Getting Started with Aurora Vision.

Camera driver software

This filter is intended to cooperate with camera using its vendor SDK. To be able to connect to camera it is required to install Fly Capture 2 SDK software with camera dedicated drivers. Currently Aurora Vision Studio requires **Fly Capture version 2.13.3.61**.

Fly Capture 2 SDK can be downloaded from the following website: https://www.teledynevisionsolutions.com/support/support-center/software-firmware-downloads (registration may be required).

For 64 bit Aurora Vision Studio it is required to install 64 bit SDK version.

Camera identification

When there is only one camera connected to computer, **inDeviceSerialNumber** field can be set to Auto. In this situation first available camera will be found and connected.

inDeviceSerialNumber can be used to pick one of multiple cameras connected to computer. Set this field to device serial number (for example "1234567", should be available on device casing as "s/n: 1234567").

Camera parameters

Most of parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameters for automatic configuration by camera driver (for example shutter time will be adjusted according to light conditions).

To change other and more advanced camera parameters use configuration tool "FlyCap2" available with Fly Capture 2 SDK. Refer to SDK documentation to find information about parameters and how to save parameters into memory channels.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

FlyCapture_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Flir camera.

Applications: Use this filter if the trigger may be not coming for some time, while the application should be performing other operations continuously (e.g. processing HMI events).

Syntax

```
bool avl::FlyCapture_GrabImage_WithTimeout
(
 FlyCapture_State& ioState,
 atl::Optional<int> inDeviceSerialNumber,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<float> inShutter,
 atl::Optional<float> inGain,
 atl::Optional<float> inExposure,
 atl::Optional<float> inFrameRate,
 atl::Optional<int> inTimeout,
 avl::FlirTriggerMode::Type inTriggerMode,
 avl::FlirColorMode::Type inColorMode,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	FlyCapture_State&			Object used to maintain state of the function.
→	inDeviceSerialNumber	Optional<int>		NIL	Source device serial number
→	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
→	inShutter	Optional<float>	0.0 – ∞	NIL	Shutter time
→	inGain	Optional<float>	0.0 – ∞	NIL	Image analog gain value
→	inExposure	Optional<float>		NIL	Exposure time
→	inFrameRate	Optional<float>	0.1 – ∞	NIL	Requested camera frame rate
→	inTimeout	Optional<int>	100 – 3600000	5000	Timeout
→	inTriggerMode	FlirTriggerMode::Type			Camera trigger mode and source control
→	inColorMode	FlirColorMode::Type			Requested grayscale or color mode of output image
←	outImage	Conditional<Image>&			Output image

This application note provides information on how to install, configure, and use Point Grey imaging cameras with Aurora Vision software: Getting Started with Aurora Vision.

Camera driver software

This filter is intended to cooperate with camera using its vendor SDK. To be able to connect to camera it is required to install Fly Capture 2 SDK software with camera dedicated drivers. Currently Aurora Vision Studio requires **Fly Capture version 2.13.3.61**.

Fly Capture 2 SDK can be downloaded from the following website: https://www.teledynevisionsolutions.com/support/support-center/software-firmware-downloads (registration may be required).

For 64 bit Aurora Vision Studio it is required to install 64 bit SDK version.

Camera identification

When there is only one camera connected to computer, **inDeviceSerialNumber** field can be set to Auto. In this situation first available camera will be found and connected.

inDeviceSerialNumber can be used to pick one of multiple cameras connected to computer. Set this field to device serial number (for example "1234567", should be available on device casing as "s/n: 1234567").

Camera parameters

Most of parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameters for automatic configuration by camera driver (for example shutter time will be adjusted according to light conditions).

To change other and more advanced camera parameters use configuration tool "FlyCap2" available with Fly Capture 2 SDK. Refer to SDK documentation to find information about parameters and how to save parameters into memory channels.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Gocator_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::Gocator_GenerateSoftwareTrigger
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress
)
```

Parameters

	Name	Type	Default	Description
	ioState	Gocator_State&		Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&	NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GetCurrentJobName

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads current job name.

Syntax

```
void avl::Gocator_GetCurrentJobName
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 atl::String& outJobName
)
```

Parameters

	Name	Type	Default	Description
	ioState	Gocator_State&		Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&	NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	outJobName	String&		Current Job name

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GetTriggerSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets current trigger source.

Syntax

```
void avl::Gocator_GetTriggerSource
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 avl::GocatorTriggerSource::Type& outTriggerSource
)
```

Parameters

	Name	Type	Default	Description
	ioState	Gocator_State&		Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&	NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	outTriggerSource	GocatorTriggerSource::Type&		Current trigger source

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabImages

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from Gocator device.

Syntax

```
bool avl::Gocator_GrabImages
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 avl::Image& outImage1,
 avl::Image& outImage2,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
←	outImage1	Image&			First output image
←	outImage2	Image&			Second output image
←	outFrameInfo	GocatorFrameInfo&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabImages_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from Gocator device.

Syntax

```
bool avl::Gocator_GrabImages_WithTimeout
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 atl::Conditional<avl::Image>& outImage1,
 atl::Conditional<avl::Image>& outImage2,
 atl::Conditional<avl::GocatorFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Gocator_State&			Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
	inTimeout	int	10 – ∞	100	Maximum time to wait for data in milliseconds
	outImage1	Conditional<Image>&			First output image
	outImage2	Conditional<Image>&			Second output image
	outFrameInfo	Conditional<GocatorFrameInfo>&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator_GrabMeasurement

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Measurement data from Gocator device.

Syntax

```
bool avl::Gocator_GrabMeasurement
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inMeasurementID,
 double& outValue,
 bool& outDecision,
 avl::GocatorDecisionCode::Type& outDecisionCode,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inMeasurementID	int	0 – ∞		
←	outValue	double&			
←	outDecision	bool&			
←	outDecisionCode	GocatorDecisionCode::Type&			
←	outFrameInfo	GocatorFrameInfo&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabMeasurement_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Measurement data from Gocator device.

Syntax

```
bool avl::Gocator_GrabMeasurement_WithTimeout
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 int inMeasurementID,
 atl::Conditional<atl::real64>& outValue,
 atl::Conditional<bool>& outDecision,
 atl::Conditional<avl::GocatorDecisionCode::Type>& outDecisionCode,
 atl::Conditional<avl::GocatorFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inTimeout	int	10 – ∞	100	
→	inMeasurementID	int	0 – ∞		
←	outValue	Conditional<real64>&			
←	outDecision	Conditional<bool>&			
←	outDecisionCode	Conditional<GocatorDecisionCode::Type>&			
←	outFrameInfo	Conditional<GocatorFrameInfo>&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabPoint3DGrid

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Point3DGrid (non resampled surface) from Gocator device.

Syntax

```
bool avl::Gocator_GrabPoint3DGrid
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 avl::Point3DGrid& outPoint3DGrid,
 atl::Conditional<avl::Image>& outSurfaceIntensity,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 - 50000		Number of incoming frames that can be buffered before the application is able to process them
←	outPoint3DGrid	Point3DGrid&			
←	outSurfaceIntensity	Conditional<Image>&			
←	outFrameInfo	GocatorFrameInfo&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** - Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabPoint3DGrid_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Point3DGrid (Un-Resampled surface) from Gocator device with timeout; returns Nil if no data comes in the specified time.

Syntax

```
bool avl::Gocator_GrabPoint3DGrid_WithTimeout
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 atl::Conditional<avl::Point3DGrid>& outPoint3DGrid,
 atl::Conditional<avl::Image>& outSurfaceIntensity,
 atl::Conditional<avl::GocatorFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inTimeout	int	10 – ∞	100	Maximum time to wait for data in milliseconds
←	outPoint3DGrid	Conditional<Point3DGrid>&			
←	outSurfaceIntensity	Conditional<Image>&			
←	outFrameInfo	Conditional<GocatorFrameInfo>&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabProfile

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures profile from Gocator device.

Syntax

```
bool avl::Gocator_GrabProfile
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 atl::Array<avl::Point2D>& outProfileData,
 atl::Conditional<avl::Profile>& outProfileIntensity,
 atl::real& outXScale,
 atl::real& outXOffset,
 atl::real& outZScale,
 atl::real& outZOffset,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Gocator_State&			Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	inInputQueueSize	int	1 - 50000		Number of incoming frames that can be buffered before the application is able to process them
	outProfileData	Array<Point2D>&			
	outProfileIntensity	Conditional<Profile>&			
	outXScale	real&			X scale in mm
	outXOffset	real&			X offset in mm
	outZScale	real&			Z scale in mm
	outZOffset	real&			Z offset in mm
	outFrameInfo	GocatorFrameInfo&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** - Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Also in AVL Lite

Gocator_GrabSection

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Section from Gocator device.

Syntax

```
bool avl::Gocator_GrabSection
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inSectionID,
 atl::Array<avl::Point2D>& outSectionData,
 atl::Conditional<avl::Profile>& outSectionIntensity,
 atl::real& outXScale,
 atl::real& outXOffset,
 atl::real& outZScale,
 atl::real& outZOffset,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inSectionID	int	0 – ∞		
←	outSectionData	Array<Point2D>&			
←	outSectionIntensity	Conditional<Profile>&			
←	outXScale	real&			X scale in mm
←	outXOffset	real&			X offset in mm
←	outZScale	real&			Z scale in mm
←	outZOffset	real&			Z offset in mm

Gocator_GrabSection_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Section from Gocator device.

Syntax

```
bool avl::Gocator_GrabSection_WithTimeout
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 int inSectionID,
 atl::Conditional<atl::Array<avl::Point2D>>& outSectionData,
 atl::Conditional<avl::Profile>& outSectionIntensity,
 atl::Conditional<atl::real>& outXScale,
 atl::Conditional<atl::real>& outXOffset,
 atl::Conditional<atl::real>& outZScale,
 atl::Conditional<atl::real>& outZOffset,
 atl::Conditional<avl::GocatorFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inTimeout	int	10 – ∞	100	
→	inSectionID	int	0 – ∞		
←	outSectionData	Conditional<Array<Point2D>>&			
←	outSectionIntensity	Conditional<Profile>&			
←	outXScale	Conditional<real>&			X scale in mm
←	outXOffset	Conditional<real>&			X offset in mm
←	outZScale	Conditional<real>&			Z scale in mm
←	outZOffset	Conditional<real>&			Z offset in mm
←	outFrameInfo	Conditional<GocatorFrameInfo>&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator emulator

This filter was tested with **Gocator emulator in version 6.1.20.8**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Gocator_GrabSurface

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Surface from Gocator device.

Syntax

```
bool avl::Gocator_GrabSurface
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 avl::Surface& outSurface,
 atl::Conditional<avl::Image>& outSurfaceIntensity,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 - 50000		Number of incoming frames that can be buffered before the application is able to process them
←	outSurface	Surface&			
←	outSurfaceIntensity	Conditional<Image>&			
←	outFrameInfo	GocatorFrameInfo&			

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** - Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator_GrabUniformProfile

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures uniform profile from Gocator device.

Syntax

```
bool avl::Gocator_GrabUniformProfile
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 avl::Profile& outProfileData,
 atl::Conditional<avl::Profile>& outProfileIntensity,
 atl::real& outZScale,
 atl::real& outZOffset,
 avl::GocatorFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Gocator_State&			Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")

Gocator_GrabUniformProfile_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures uniform profile from Gocator device.

Syntax

```
bool avl::Gocator_GrabUniformProfile_WithTimeout
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 atl::Conditional<avl::Profile>& outProfileData,
 atl::Conditional<avl::Profile>& outProfileIntensity,
 atl::Conditional<atl::real>& outZScale,
 atl::Conditional<atl::real>& outZOffset,
 atl::Conditional<avl::GocatorFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Gocator_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")

Gocator_LoadJob

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Loads new job.

Syntax

```
void avl::Gocator_LoadJob
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 const atl::String& inJobName
)
```

Parameters

	Name	Type	Default	Description
	ioState	Gocator_State&		Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&	NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	inJobName	const String&		Job name. The name must end with: ".job"

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a Gocator device.

Syntax

```
void avl::Gocator_StartAcquisition
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress,
 int inInputQueueSize,
 atl::Optional<avl::GocatorTriggerSource::Type> inTriggerSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Gocator_State&			Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&		NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")
	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
	inTriggerSource	Optional<GocatorTriggerSource::Type>		NIL	Configure Gocator trigger source

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – Gocator Device identifying IP address (e.g. "127.0.0.1")
- **Serial Number** – Gocator Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a Gocator device.

Syntax

```
void avl::Gocator_StopAcquisition
(
 Gocator_State& ioState,
 const atl::Optional<avl::GocatorAddress>& inAddress
)
```

Parameters

	Name	Type	Default	Description
	ioState	Gocator_State&		Object used to maintain state of the function.
	inAddress	const Optional<GocatorAddress>&	NIL	Gocator Device identifying IP address (e.g. "127.0.0.1") or serial number (e.g. "SN:17335")

Remarks

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

GoPxL_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger.

Syntax

```
void avl::GoPxL_GenerateSoftwareTrigger
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress
)
```

Parameters

	Name	Type	Default	Description
	ioState	GoPxL_State&		Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&	NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** – GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GoPxL_GetCurrentJobName

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads the current job name.

Syntax

```
void avl::GoPxL_GetCurrentJobName
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 atl::String& outJobName
)
```

Parameters

	Name	Type	Default	Description
	ioState	GoPxL_State&		Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&	NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
	outJobName	String&		Current job name

Remarks

Device driver software

Also in AVL Lite

GoPxL_GrabCircle

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Circle Feature data from GoPxL device.

Syntax

```
bool avl::GoPxL_GrabCircle
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 int inInputQueueSize,
 atl::Optional<int> inSourceID,
 avl::GoPxLCircle& outCircle,
 avl::GoPxLFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	GoPxL_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inSourceID	Optional<int>	0 – ∞	NIL	ID of the data source in Gocator Protocol
←	outCircle	GoPxLCircle&			Circle
←	outFrameInfo	GoPxLFrameInfo&			Frame metadata

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** – GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator Protocol data source ID

When the field **inSourceID** is set to Auto, all data sources of a specific type would be processed by this filter. To process only one, chosen data source, set the value of this field to an appropriate ID. Data source IDs can be found in the GoPxL web interface, under Control/Gocator tab.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

 atl::Conditional<avl::GoPxLCircle>& outCircle,
 atl::Conditional<avl::GoPxLFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	GoPxL_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inTimeout	Optional<int>	10 – ∞	100	Maximum time to wait for data in milliseconds
→	inSourceID	Optional<int>	0 – ∞	NIL	ID of the data source in Gocator Protocol
←	outCircle	Conditional<GoPxLCircle>&			Circle
←	outFrameInfo	Conditional<GoPxLFrameInfo>&			Frame metadata

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** – GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator Protocol data source ID

When the field **inSourceID** is set to Auto, all data sources of a specific type would be processed by this filter. To process only one, chosen data source, set the value of this field to an appropriate ID. Data source IDs can be found in the GoPxL web interface, under Control/Gocator tab.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GoPxL_GrabImages

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from GoPxL device.

Syntax

```
bool avl::GoPxL_GrabImages
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 int inInputQueueSize,
 atl::Optional<int> inSourceID1,
 atl::Optional<int> inSourceID2,
 avl::Image& outImage1,
 avl::Image& outImage2,
 avl::GoPxLFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	GoPxL_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inSourceID1	Optional<int>	-1 – ∞	NIL	ID of the data source in Gocator Protocol 1
→	inSourceID2	Optional<int>	-1 – ∞	NIL	ID of the data source in Gocator Protocol 2
←	outImage1	Image&			Image 1
←	outImage2	Image&			Image 2
←	outFrameInfo	GoPxLFrameInfo&			Frame metadata

GoPxL_GrabPoint3DGrid

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Point3DGrid (not resampled surface) from GoPxL device.

Syntax

```
bool avl::GoPxL_GrabPoint3DGrid
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 int inInputQueueSize,
 atl::Optional<int> inSourceID,
 avl::Point3DGrid& outPoint3DGrid,
 atl::Conditional<avl::Image>& outSurfaceIntensity,
 avl::GoPxLFrameInfo& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	GoPxL_State&			Object used to maintain state of the function.
→	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
→	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
→	inSourceID	Optional<int>	0 – ∞	NIL	ID of the data source in Gocator Protocol
←	outPoint3DGrid	Point3DGrid&			Point3DGrid
←	outSurfaceIntensity	Conditional<Image>&			SurfaceIntensity
←	outFrameInfo	GoPxLFrameInfo&			Frame metadata

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** – GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator Protocol data source ID

When the field **inSourceID** is set to Auto, all data sources of a specific type would be processed by this filter. To process only one, chosen data source, set the value of this field to an appropriate ID. Data source IDs can be found in the GoPxL web interface, under Control/Gocator tab.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- GoPxL_GrabPoint3DGrid – Captures Point3DGrid (not resampled surface) from GoPxL device.
- GoPxL_GrabPoint3DGrid_WithTimeout – Captures Point3DGrid (not resampled surface) from GoPxL device with timeout; returns Nil if no data comes in the specified time.
- GoPxL_GrabProfile – Captures profile from GoPxL device.
- GoPxL_GrabProfile_WithTimeout – Captures profile from GoPxL device.
- GoPxL_GrabSurface – Captures Surface from GoPxL device.
- GoPxL_GrabSurface_WithTimeout – Captures Surface from GoPxL device with timeout; returns Nil if no data comes in the specified time.

GoPxL_GrabUniformProfile_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures uniform profile from GoPxL device.

Syntax

```
bool avl::GoPxL_GrabUniformProfile_WithTimeout
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 int inInputQueueSize,
 int inTimeout,
 atl::Optional<int> inSourceID,
 atl::Conditional<avl::Profile>& outProfileData,
 atl::Conditional<avl::Profile>& outProfileIntensity,
 atl::Conditional<atl::real>& outZScale,
 atl::Conditional<atl::real>& outZOffset,
 atl::Conditional<avl::GoPxLFrameInfo>& outFrameInfo
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	GoPxL_State&			Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
	inTimeout	int	10 – ∞	100	Maximum time to wait for data in milliseconds
	inSourceID	Optional<int>	0 – ∞	NIL	ID of the data source in Gocator Protocol
	outProfileData	Conditional<Profile>&			ProfileData
	outProfileIntensity	Conditional<Profile>&			ProfileIntensity
	outZScale	Conditional<real>&			Z scale in mm
	outZOffset	Conditional<real>&			Z offset in mm
	outFrameInfo	Conditional<GoPxLFrameInfo>&			Frame metadata

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** – GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** – GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Gocator Protocol data source ID

When the field **inSourceID** is set to Auto, all data sources of a specific type would be processed by this filter. To process only one, chosen data source, set the value of this field to an appropriate ID. Data source IDs can be found in the GoPxL web interface, under Control/Gocator tab.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GoPxL_GrabImages_WithTimeout – Captures images from GoPxL device.
- GoPxL_GrabPoint3DGrid – Captures Point3DGrid (not resampled surface) from GoPxL device.
- GoPxL_GrabPoint3DGrid_WithTimeout – Captures Point3DGrid (not resampled surface) from GoPxL device with timeout; returns Nil if no data comes in the specified time.
- GoPxL_GrabProfile – Captures profile from GoPxL device.
- GoPxL_GrabProfile_WithTimeout – Captures profile from GoPxL device.
- GoPxL_GrabSurface – Captures Surface from GoPxL device.
- GoPxL_GrabSurface_WithTimeout – Captures Surface from GoPxL device with timeout; returns Nil if no data comes in the specified time.

GoPxL_LoadJob

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Loads a new job.

Syntax

```
void avl::GoPxL_LoadJob
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 const atl::String& inJobName
)
```

Parameters

	Name	Type	Default	Description
	ioState	GoPxL_State&		Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&	NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
	inJobName	const String&		Job name

Remarks

Device driver software

This filter is intended to cooperate with a Gocator device running GoPxL firmware. It is not required to install any additional software to connect to the device. **Required firmware version >= 1.1.11.1**.

Device identification

When there is only one device connected, the field **inAddress** can be set to Auto. In this situation, the first available device will be used.

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600")
- **Serial Number** - GoPxL Device serial number with "SN:" prefix (e.g. "SN:17335")

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GoPxL_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a GoPxL device.

Syntax

```
void avl::GoPxL_StartAcquisition
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress,
 int inInputQueueSize,
 atl::Optional<avl::GoPxLTriggerSource::Type> inTriggerSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	GoPxL_State&			Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&		NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")
	inInputQueueSize	int	1 – 50000		Number of incoming frames that can be buffered before the application is able to process them
	inTriggerSource	Optional<GoPxLTriggerSource::Type>		NIL	GoPxL Device trigger source

Remarks

Device driver software

- GoPxL_StopAcquisition – Stops image acquisition in a GoPxL device.

GoPxL_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a GoPxL device.

Syntax

```
void avl::GoPxL_StopAcquisition
(
 GoPxL_State& ioState,
 const atl::Optional<avl::GoPxLAddress>& inAddress
)
```

Parameters

	Name	Type	Default	Description
	ioState	GoPxL_State&		Object used to maintain state of the function.
	inAddress	const Optional<GoPxLAddress>&	NIL	GoPxL Device identifying IP address (e.g. "127.0.0.1" or "127.0.0.1:3600") or serial number (e.g. "SN:17335")

Remarks

Hikrobot_GetFirmwareVersion

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get Hikrobot IO firmware version.

Syntax

```
void avl::Hikrobot_GetFirmwareVersion
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 atl::String& outFirmwareVersion,
 atl::String& outFirmwareDate
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
	outFirmwareVersion	String&			Firmware version.
	outFirmwareDate	String&			Firmware date formatted as YYYY-mm-dd.

Remarks

This filter allows to check the firmware version of the device.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Hikrobot_GetSdkVersion – Get Hikrobot SDK version.

Hikrobot_GetInputLevel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get input level information. When edge detection is on, the interface cannot be used to obtain the level.

Syntax

```
void avl::Hikrobot_GetInputLevel
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hikrobot_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number - COM port number.
→	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
←	outLevel	bool&			Logic level information for the specified port.

Remarks

This filter allows to get the input level information of a specific port of the device. When edge detection is on, the interface cannot be used to obtain the level.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** - the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_GetInputParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get input parameters.

Syntax

```
void avl::Hikrobot_GetInputParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 int& outEnableState,
 avl::HikrobotEdgeType::Type& outTriggerEdge,
 int& outTriggerDelay,
 int& outDebounceTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number - COM port number.
	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
	outEnableState	int&			Enable state (1 is on, 0 is off).
	outTriggerEdge	HikrobotEdgeType::Type&			Trigger edge.
	outTriggerDelay	int&			Trigger delay [ms].
	outDebounceTime	int&			Contact debounce time [ms].

Remarks

This filter allows to get the input parameters of a specific port of the device. The parameters are enable state, trigger edge, trigger delay and contact debounce time.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** - the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- Hikrobot_SetInputParameters - Set input parameters.
- Hikrobot_GetOutputParameters - Get output parameters.

Hikrobot_GetLightParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get light parameters.

Syntax

```
void avl::Hikrobot_GetLightParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotLightPortNumber::Type inPortNumber,
 int& outLightValue,
 avl::HikrobotLightState::Type& outLightState,
 avl::HikrobotEdgeType::Type& outTriggerEdge,
 int& outDurationTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number - COM port number.
	inPortNumber	HikrobotLightPortNumber::Type			Device light port number reference.
	outLightValue	int&			Light brightness value [0-100].
	outLightState	HikrobotLightState::Type&			Light state after triggering.
	outTriggerEdge	HikrobotEdgeType::Type&			Trigger edge.
	outDurationTime	int&			Duration time [ms].

Remarks

This filter allows to get the parameters of a specific light port of the device. The parameters are brightness value, state after triggering, trigger edge and duration time.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** - the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_GetOutputParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get output parameters.

Syntax

```
void avl::Hikrobot_GetOutputParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 avl::HikrobotPatternOut::Type& outMode,
 int& outPulseWidth,
 int& outPulsePeriod,
 int& outPulseDuration,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hikrobot_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
→	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
←	outMode	HikrobotPatternOut::Type&			Output mode: Single pulse or PWM.
←	outPulseWidth	int&			PWM pulse width [ms].
←	outPulsePeriod	int&			PWM pulse period [ms].
←	outPulseDuration	int&			PWM pulse duration [ms].
←	outLevel	bool&			Effective level (there may be reversed logic).

Remarks

This filter allows to get the output parameters of a specific port of the device. The parameters are output mode (Single pulse or PWM), PWM pulse width, PWM pulse period, PWM pulse duration and effective level.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_GetSdkVersion

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get Hikrobot SDK version.

Syntax

```
void avl::Hikrobot_GetSdkVersion
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 atl::String& outSdkVersion,
 atl::String& outSdkDate
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hikrobot_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
←	outSdkVersion	String&			SDK version.
←	outSdkDate	String&			SDK date formatted as YYYY-mm-dd.

Remarks

This filter allows to check the installed SDK version. It can also be used for testing purposes, e.g. to see whether the SDK has been properly configured in the operating system.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Hikrobot_GetFirmwareVersion – Get Hikrobot IO firmware version.

Hikrobot_Reboot

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reboot the I/O device.

Syntax

```
void avl::Hikrobot_Reboot
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number - COM port number.

Remarks

This filter allows to reboot the I/O hardware of the device.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** - the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_ResetAllParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reset all I/O parameters to default values.

Syntax

```
void avl::Hikrobot_ResetAllParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.

Remarks

This filter allows to reset all parameters of the I/O, including the configuration of inputs, outputs and lights.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_SetInputParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set input parameters.

Syntax

```
void avl::Hikrobot_SetInputParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 int inEnableState,
 avl::HikrobotEdgeType::Type inTriggerEdge,
 int inTriggerDelay,
 int inDebounceTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
	inEnableState	int	0 – 1	0	Enable state (1 is on, 0 is off).
	inTriggerEdge	HikrobotEdgeType::Type		MvIoEdgeRising	Trigger edge.
	inTriggerDelay	int	0 – 1000	20	Trigger delay [ms].
	inDebounceTime	int	0 – 1000	20	Contact debounce time [ms].

Remarks

This filter allows to set the input parameters of a specific port of the device. The parameters are enable state, trigger edge, trigger delay and contact debounce time.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_SetLightParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set light parameters.

Syntax

```
void avl::Hikrobot_SetLightParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotLightPortNumber::Type inPortNumber,
 int inLightValue,
 avl::HikrobotLightState::Type inLightState,
 avl::HikrobotEdgeType::Type inTriggerEdge,
 int inDurationTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
	inPortNumber	HikrobotLightPortNumber::Type			Device light port number reference.
	inLightValue	int	0 – 100	20	Light brightness value [0–100].
	inLightState	HikrobotLightState::Type		MvIoLightStateOff	Light state after triggering.
	inTriggerEdge	HikrobotEdgeType::Type		MvIoEdgeRising	Trigger edge.
	inDurationTime	int	0 – 65535	200	Duration time [ms].

Remarks

This filter allows to set the parameters of a specific light port of the device. The parameters are brightness value, state after triggering, trigger edge and duration time.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_SetOutputEnable

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Turn on output enable.

Syntax

```
void avl::Hikrobot_SetOutputEnable
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 avl::HikrobotEnableType::Type inEnableType
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
	inEnableType	HikrobotEnableType::Type			Start or stop enabling.

Remarks

This filter allows to enable or disable output of a specific port of the device.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

- **COM port number** – the number of the COM port used to communicate with the I/O.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Hikrobot_SetOutputParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set output parameters.

Syntax

```
void avl::Hikrobot_SetOutputParameters
(
 Hikrobot_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::HikrobotPortNumber::Type inPortNumber,
 avl::HikrobotPatternOut::Type inMode,
 int inPulseWidth,
 int inPulsePeriod,
 int inPulseDuration,
 bool inLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikrobot_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identification number – COM port number.
	inPortNumber	HikrobotPortNumber::Type			Device port number reference.
	inMode	HikrobotPatternOut::Type		MvIoPatternSingle	Output mode: Single pulse or PWM.
	inPulseWidth	int	1 – 65535		PWM pulse width [ms].
	inPulsePeriod	int	1 – 65535	1	PWM pulse period [ms].
	inPulseDuration	int	1 – 65535	20	PWM pulse duration [ms].
	inLevel	bool		True	Effective level (there may be reversed logic).

Remarks

This filter allows to set the output parameters of a specific port of the device. The parameters are output mode (Single pulse or PWM), PWM pulse width, PWM pulse period, PWM pulse duration and effective level.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Hikrobot VC4000 SDK.

Add DLL path to system environment variable is required.

In some computer models, digital inputs and outputs may operate in reverse logic (true is low signal level). Please check your device.

Recommended Hikrobot VC4000 SDK version for Aurora Vision Studio usage is **1.2.0**.

Device identification

inDeviceID field can be used to pick one of multiple I/Os connected to computer. DeviceID can be set to:

HIK Hikvision_ConfigureStrobe

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobe parameters.

Syntax

```
void avl::Hikvision_ConfigureStrobe
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::HikvisionLine::Type inLineSelector,
 avl::HikvisionEvent::Type inLineSource,
 atl::Optional<bool> inLineInverter,
 bool inStrobeEnabled,
 atl::Optional<int> inStrobeDuration,
 atl::Optional<int> inStrobeDelay
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikvision_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number, name or IP address, Auto = first camera
	inLineSelector	HikvisionLine::Type			Strobe output line
	inLineSource	HikvisionEvent::Type		ExposureActive	Strobe source
	inLineInverter	Optional<bool>		NIL	True if inverting output signal
	inStrobeEnabled	bool			True if using strobe on selected line
	inStrobeDuration	Optional<int>	0 – ∞	NIL	Duration of strobe pulse in microseconds
	inStrobeDelay	Optional<int>	0 – ∞	NIL	Delay of strobe pulse in microseconds

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Hikvision Machine Vision Software with camera dedicated drivers.

Hikvision Machine Vision Software can be downloaded from the following website: https://www.hikrobotics.com/en/machinevision/service/download?module=0 (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Hikvision Machine Vision Software version for Aurora Vision Studio usage is **4.4.0** (DLL version **4.4.1.3**).

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – serial number of the device which can be viewed in the MVS software from Hikvision under Feature Tree / Device Control / Device Serial Number. Please note that this serial number may differ from the one printed on the device housing.
- **Camera name** – user-defined ID which can be set in the MVS software from Hikvision under Feature Tree / Device Control / Device User ID.
- **IP address** – ip address of the camera on the local network.

Setting bandwidth for GigEVision cameras

Bandwidth of Hikvision GigEVision cameras needs to be configured before use, otherwise packet loss and image artifacts may occur.

Open MVS software from Hikvision and connect to the camera. Open Settings / Options menu and go to Network tab. Bandwidth Control slider will be shown. To preserve new value of bandwidth after disconnecting power from the camera, you will need to save it using User Set Control parameters in Features tab.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hikvision_ConfigureTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets triggering parameters.

Syntax

```
void avl::Hikvision_ConfigureTrigger
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<bool> inTriggerEnabled,
 atl::Optional<avl::HikvisionEvent::Type> inTriggerSelector,
 atl::Optional<avl::HikvisionTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::HikvisionTriggerActivation::Type> inTriggerActivation,
 atl::Optional<float> inTriggerDelay
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hikvision_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number, name or IP address, Auto = first camera
	inTriggerEnabled	Optional<bool>		False	True if using trigger
	inTriggerSelector	Optional<HikvisionEvent::Type>		FrameBurstStart	Triggering event selection
	inTriggerSource	Optional<HikvisionTriggerSource::Type>		Line0	Trigger source
	inTriggerActivation	Optional<HikvisionTriggerActivation::Type>		RisingEdge	Trigger polarity
	inTriggerDelay	Optional<float>	0.0 - ∞	0.0f	Delay of trigger in microseconds

Hikvision_GetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool.

Syntax

```
void avl::Hikvision_GetBoolParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Hikvision_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	bool&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hikvision_GetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enum.

Syntax

```
void avl::Hikvision_GetEnumParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Hikvision_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	String&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

HIK Hikvision_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::Hikvision_GetIntegerParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Hikvision_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	int&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

HIK Hikvision_GetRealParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Real.

Syntax

```
void avl::Hikvision_GetRealParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Hikvision_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	float&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hikvision_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::Hikvision_GetStringParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Hikvision_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
	inParameterName	const String&		Name of parameter
	outParameterValue	String&		Value of parameter

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hikvision_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a Hikvision device.

Syntax

```
bool avl::Hikvision_GrabImage
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::HikvisionPixelFormat::Type inPixelFormat,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<float> inFrameRate,
 bool inFrameRateAuto,
 atl::Optional<float> inExposureTime,
 bool inExposureTimeAuto,
 atl::Optional<float> inGain,
 bool inGainAuto,
 avl::Image& outImage,
 atl::Conditional<int>& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hikvision_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Camera serial number, name or IP address, Auto = first camera
→	inInputQueueSize	int	1 – ∞	8	Sets size of image queue (on acquisition start)
→	inPixelFormat	HikvisionPixelFormat::Type			Image pixel format (set on acquisition start)
→	inRoi	Optional<const Box&>		NIL	Region of interest (set on acquisition start)
→	inFrameRate	Optional<float>	0.0 – ∞	NIL	Sets the frame rate limit
→	inFrameRateAuto	bool		True	True if frame rate is not limited
→	inExposureTime	Optional<float>	0.0 – ∞	10000.0f	Sets the target exposure time in microseconds
→	inExposureTimeAuto	bool			True if using automatic exposure time
→	inGain	Optional<float>	0.0 – ∞	0.0f	Sets gain in dB
→	inGainAuto	bool			True if using automatic gain
←	outImage	Image&			Captured frame
←	outFrameID	Conditional<int>&			Captured frame ID

Sets parameter of type String.

Syntax

```
void avl::Hikvision_SetStringParameter
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Hikvision_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	const String&		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hikvision_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a device.

Syntax

```
void avl::Hikvision_StartAcquisition
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::HikvisionPixelFormat::Type inPixelFormat,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<float> inFrameRate,
 bool inFrameRateAuto,
 atl::Optional<float> inExposureTime,
 bool inExposureTimeAuto,
 atl::Optional<float> inGain,
 bool inGainAuto
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hikvision_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Camera serial number, name or IP address, Auto = first camera
→	inInputQueueSize	int	1 – ∞	8	Sets size of image queue (on acquisition start)
→	inPixelFormat	HikvisionPixelFormat::Type			Image pixel format (set on acquisition start)
→	inRoi	Optional<const Box&>		NIL	Region of interest (set on acquisition start)
→	inFrameRate	Optional<float>	0.0 – ∞	NIL	Sets the frame rate limit
→	inFrameRateAuto	bool		True	True if frame rate is not limited
→	inExposureTime	Optional<float>	0.0 – ∞	10000.0f	Sets the target exposure time in microseconds
→	inExposureTimeAuto	bool			True if using automatic exposure time
→	inGain	Optional<float>	0.0 – ∞	0.0f	Sets gain in dB
→	inGainAuto	bool			True if using automatic gain

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Hikvision Machine Vision Software with camera dedicated drivers.

Hikvision Machine Vision Software can be downloaded from the following website: https://www.hikrobotics.com/en/machinevision/service/download?module=0 (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Hikvision Machine Vision Software version for Aurora Vision Studio usage is **4.4.0** (DLL version **4.4.1.3**).

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – serial number of the device which can be viewed in the MVS software from Hikvision under Feature Tree / Device Control / Device Serial Number. Please note that this serial number may differ from the one printed on the device housing.
- **Camera name** – user-defined ID which can be set in the MVS software from Hikvision under Feature Tree / Device Control / Device User ID.
- **IP address** – ip address of the camera on the local network.

Setting bandwidth for GigEVision cameras

Bandwidth of Hikvision GigEVision cameras needs to be configured before use, otherwise packet loss and image artifacts may occur.

Open MVS software from Hikvision and connect to the camera. Open Settings / Options menu and go to Network tab. Bandwidth Control slider will be shown. To preserve new value of bandwidth after disconnecting power from the camera, you will need to save it using User Set Control parameters in Features tab.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- Hikvision_GrabImage – Captures an image from a Hikvision device.
- Hikvision_GrabImage_WithTimeout – Captures an image from a Hikvision device.

Hikvision_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a device.

Syntax

```
void avl::Hikvision_StopAcquisition
(
 Hikvision_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Hikvision_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number, name or IP address, Auto = first camera

Hilscher_Channel_Close

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Closes a Hilscher device channel connection.

Syntax

```
void avl::Hilscher_Channel_Close
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const bool inCloseCommunication
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 - 10		
	inCloseCommunication	const bool		False	Close communication between card and PLC

Remarks

Driver

- Windows driver (recommended **1.5.0.0**)
  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

For profinet: Firmware (recommended **3.13** series)
https://hilscher.atlassian.net/wiki/spaces/PNS3V5/pages/123210653/Expired+Versions+-+V3.5+to+V3.x

Firmware needs to be uploaded to the card prior to opening any type of channel.

Hilscher_Channel_GetSignals

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Retrieves the current slot configuration.

Syntax

```
void avl::Hilscher_Channel_GetSignals
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 atl::Array<avl::HilscherSignal>& outInputSignals,
 atl::Array<avl::HilscherSignal>& outOutputSignals
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 – 10		
←	outInputSignals	Array<HilscherSignal>&			
←	outOutputSignals	Array<HilscherSignal>&			

Also in AVL Lite

Hilscher_Channel_GetSlots

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Retrieves the current slot configuration.

Syntax

```
void avl::Hilscher_Channel_GetSlots
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 atl::Array<avl::HilscherSlot>& outSlots
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 – 10		
←	outSlots	Array<HilscherSlot>&			

Also in AVL Lite

Hilscher_Channel_IndexRead_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IndexRead_ByteBuffer
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inIndex,
 const int inSize,
 avl::ByteBuffer& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inIndex	const int	0 – 1000		
	inSize	const int	1 – ∞		
	outData	ByteBuffer&			

Also in AVL Lite

Hilscher_Channel_IndexRead_SInt16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IndexRead_SInt16
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inIndex,
 const avl::DataEndianness::Type inDataEndianness,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inIndex	const int	0 – 1000

	outData	sint64&			

Also in AVL Lite

Hilscher_Channel_IndexRead_SInt8

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IndexRead_SInt8
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inIndex,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 - 10		
	inIndex	const int	0 - 1000		
	outData	int&			

Also in AVL Lite

Hilscher_Channel_IndexWrite_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IndexWrite_ByteBuffer
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inIndex,
 const avl::ByteBuffer& inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 - 10

	inData	const sint64			

Also in AVL Lite

Hilscher_Channel_IndexWrite_SInt8

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IndexWrite_SInt8
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inIndex,
 const int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 - 10		
	inIndex	const int	0 - 1000		
	inData	const int	-128 - 127		

Hilscher_Channel_IORead_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IORead_ByteBuffer
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 const int inSize,
 avl::ByteBuffer& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inOffset	const int	0 – 10000		
	inSize	const int	1 – ∞		
	outData	ByteBuffer&			

Hilscher_Channel_IORead_SInt16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IORead_SInt16
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 const avl::DataEndianness::Type inDataEndianness,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 - 10		
→	inOffset	const int	0 - 10000		
→	inDataEndianness	const DataEndianness::Type		BigEndian	
←	outData	int&			

Remarks

Driver

- Windows driver (recommended **1.5.0.0**)
  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

For profinet: Firmware (recommended **3.13** series)
https://hilscher.atlassian.net/wiki/spaces/PNS3V5/pages/123210653/Expired+Versions+-+V3.5+to+V3.x

Firmware needs to be uploaded to the card prior to opening any type of channel.
In case of failing to update the firmware, try to restart your computer.

IO Offset (inOffset)

Offset as displayed in Hilscher software

Data direction

Slot direction is from the application perspective, different than in SYCON software.
IN: in SYCON.net is marked as output
OUT: in SYCON.net is marked as input

Data endianness

Remember to check endianness on controller and device sides, most controllers will use big endian. Data written to the card will be converted by default to network order. (to big endian)
Data read from the card will be converted to native byte order. (by default from big endian)

Hilscher_Channel_IORead_SInt32

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IORead_SInt32
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 const avl::DataEndianness::Type inDataEndianness,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 - 10		
	inOffset	const int	0 - 10000		
	inDataEndianness	const DataEndianness::Type		BigEndian	
	outData	int&

  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

For profinet: Firmware (recommended **3.13** series)
https://hilscher.atlassian.net/wiki/spaces/PNS3V5/pages/123210653/Expired+Versions+-+V3.5+to+V3.x

Firmware needs to be uploaded to the card prior to opening any type of channel.
In case of failing to update the firmware, try to restart your computer.

IO Offset (inOffset)

Offset as displayed in Hilscher software

Data direction

Slot direction is from the application perspective, different than in SYCON software.
IN: in SYCON.net is marked as output
OUT: in SYCON.net is marked as input

Data endianness

Remember to check endianness on controller and device sides, most controllers will use big endian. Data written to the card will be converted by default to network order. (to big endian)
Data read from the card will be converted to native byte order. (by default from big endian)

Hilscher_Channel_IORead_SInt8

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IORead_SInt8
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 – 10		
→	inOffset	const int	0 – 10000		
←	outData	int&			

Remarks

Driver

- Windows driver (recommended **1.5.0.0**)
  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

Hilscher_Channel_IOWrite_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IOWrite_ByteBuffer
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 const avl::ByteBuffer& inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inOffset	const int	0 – 10000		
	inData	const ByteBuffer&			

Hilscher_Channel_IOWrite_SInt16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_IOWrite_SInt16
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inOffset,
 const avl::DataEndianness::Type inDataEndianness,
 const int inData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inOffset	const int	0 – 10000		
	inDataEndianness	const DataEndianness::Type		BigEndian	
	inData	const int	-32768 – 32767		

Remarks

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hilscher_Channel_Open_Profinet

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Opens a Hilscher device channel connection.

Syntax

```
void avl::Hilscher_Channel_Open_Profinet
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const atl::Optional<atl::File> inConfig,
 const atl::Optional<atl::File> inNwid,
 const atl::Optional<atl::Array<avl::HilscherSignal>>& inInputSignalConfiguration,
 const atl::Optional<atl::Array<avl::HilscherSignal>>& inOutputSignalConfiguration
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inConfig	const Optional<File>		NIL	Configuration file generated in SYCON.net (xxx.nxd)
	inNwid	const Optional<File>		NIL	Configuration file generated in SYCON.net (xxx_nwid.nxd)
	inInputSignalConfiguration	const Optional<Array<HilscherSignal>>&		NIL	
	inOutputSignalConfiguration	const Optional<Array<HilscherSignal>>&		NIL	

Remarks

Initial state

Opening an not configured channel sets all output slots to 0, configured channel data is left as it was.

Channel configuration

The channel is only configured with provided configuration files, if it is in a not configured state – no connection between card and master device (for example a PLC). If it is configured, the filter assumes proper operation, and leaves card configuration in existing condition.

Driver

- Windows driver (recommended **1.5.0.0**)
  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

For profinet: Firmware (recommended **3.13** series)
https://hilscher.atlassian.net/wiki/spaces/PNS3V5/pages/123210653/Expired+Versions+-+V3.5+to+V3.x

Firmware needs to be uploaded to the card prior to opening any type of channel.
In case of failing to update the firmware, try to restart your computer.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hilscher_Channel_SetSignalConfiguration

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the slot configuration.

Syntax

```
void avl::Hilscher_Channel_SetSignalConfiguration
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const atl::Array<avl::HilscherSignal>& inInputSignalConfiguration,
 const atl::Array<avl::HilscherSignal>& inOutputSignalConfiguration
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inInputSignalConfiguration	const Array<HilscherSignal>&			
	inOutputSignalConfiguration	const Array<HilscherSignal>&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Hilscher_Channel_SlotRead_ByteBuffer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_SlotRead_ByteBuffer
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inSlot,
 const int inSize,
 avl::ByteBuffer& outData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Hilscher_State&			Object used to maintain state of the function.
	inBoardName	const Optional<String>&		NIL	
	inChannelNumber	const int	0 – 10		
	inSlot	const int	0 – 1000		
	inSize	const int	1 – ∞		
	outData	ByteBuffer&			

Hilscher_Channel_SlotRead_SInt16

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_SlotRead_SInt16
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inSlot,
 const avl::DataEndianness::Type inDataEndianness,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 – 10		
→	inSlot	const int	0 – 1000		
→	inDataEndianness	const DataEndianness::Type		BigEndian	
←	outData	int&			

Remarks

Driver

- Windows driver (recommended **1.5.0.0**)
  https://hilscher.atlassian.net/wiki/spaces/CIFXDRV/pages/80904655/V1.5.0.0+NXDRVWIN
- SYCON.net for configuring slots, generating configuration files:
  https://hilscher.atlassian.net/wiki/spaces/SYCON/pages/107086738/Version+History

For profinet: Firmware (recommended **3.13** series)
https://hilscher.atlassian.net/wiki/spaces/PNS3V5/pages/123210653/Expired+Versions+-+V3.5+to+V3.x

Firmware needs to be uploaded to the card prior to opening any type of channel.
In case of failing to update the firmware, try to restart your computer.

inSlot

Slot as configured in Profinet/Hilscher software

Data direction

Slot direction is from the application perspective, different than in SYCON software.
IN: in SYCON.net is marked as output
OUT: in SYCON.net is marked as input

Data endianness

Remember to check endianness on controller and device sides, most controllers will use big endian. Data written to the card will be converted by default to network order. (to big endian)
Data read from the card will be converted to native byte order. (by default from big endian)

Also in AVL Lite

Hilscher_Channel_SlotRead_SInt32

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Receives generic packet that can be filled with any data through Hilscher device.

Syntax

```
void avl::Hilscher_Channel_SlotRead_SInt32
(
 avl::Hilscher_State& ioState,
 const atl::Optional<atl::String>& inBoardName,
 const int inChannelNumber,
 const int inSlot,
 const avl::DataEndianness::Type inDataEndianness,
 int& outData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Hilscher_State&			Object used to maintain state of the function.
→	inBoardName	const Optional<String>&		NIL	
→	inChannelNumber	const int	0 – 10		
→	inSlot	const int	0 – 1000		
→	inDataEndianness	const DataEndianness::Type		BigEndian	
←	outData	int&

ICImagingControl_EnableExternalTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Controls camera external trigger.

Syntax

```
void avl::ICImagingControl_EnableExternalTrigger
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 bool inEnable
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inEnable	bool		External trigger state

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. To work with the IC Imaging Control 4 SDK you need to install the SDK on the target machine or copy manually the ic4core.dll file from the SDK installation directory (typically IC Imaging Control 4\bin\x64\) to the Aurora Vision Studio directory in Program Files. Alternatively, set the IC4PATH environment variable to the SDK installation directory.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, the first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- serial number,
- display name,
- unique name,
- base name of the camera.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICImagingControl_GetDigitalIOState – Gets digital IO lines state.
- ICImagingControl_SetDigitalOutputState – Sets digital IO line state.
- ICImagingControl_GrabImage – Captures a frame from The Imaging Source cameras using ICImagingControl.

ICImagingControl_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a boolean parameter of the camera.

Syntax

```
void avl::ICImagingControl_GetBoolParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ICImagingControlState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
→	inParameterName	const String&		Name of the parameter
←	outValue	bool&		Value of the parameter

Description

Gets a boolean parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

ICImagingControl_GetDigitalIOState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets digital IO lines state.

Syntax

```
void avl::ICImagingControl_GetDigitalIOState
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 bool& outInputState,
 bool& outOutputState
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	outInputState	bool&		Digital input state
	outOutputState	bool&		Digital output state

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

ICImagingControl_GetDoubleParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a double parameter of the camera.

Syntax

```
void avl::ICImagingControl_GetDoubleParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ICImagingControlState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
→	inParameterName	const String&		Name of the parameter
←	outValue	double&		Value of the parameter

Description

Gets a double-precision floating-point parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

ICImagingControl_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enumeration parameter of the camera.

Syntax

```
void avl::ICImagingControl_GetEnumParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ICImagingControlState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
→	inParameterName	const String&		Name of the parameter
←	outValue	String&		Enumeration entry name

Description

Gets an enumeration parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface. The value is returned as the enumeration entry name string.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. ICImagingControl_GetLongParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an integer parameter of the camera.

Syntax

```
void avl::ICImagingControl_GetLongParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 atl::sint64& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ICImagingControlState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
→	inParameterName	const String&		Name of the parameter
←	outValue	sint64&		Value of the parameter

Description

Gets an integer (64-bit) parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. ICImagingControl_GetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a string parameter of the camera.

Syntax

```
void avl::ICImagingControl_GetStringParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	ICImagingControlState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
→	inParameterName	const String&		Name of the parameter
←	outValue	String&		Value of the parameter

Description

Gets a string parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

- ICImagingControl_SetStringParameter – Sets a string parameter of the camera.

ICImagingControl_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame from The Imaging Source cameras using ICImagingControl.

Syntax

```
bool avl::ICImagingControl_GrabImage
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 int inInputQueueSize,
 const avl::ICImagingControlColorFormat::Type inPixelFormat,
 const atl::Optional<int> inBinning,
 const atl::Optional<int> inSkipping,
 const atl::Optional<avl::Box> inRoi,
 const atl::Optional<float> inFrameRate,
 const atl::Optional<int> inGain,
 const atl::Optional<bool> inGainAuto,
 const atl::Optional<double> inExposure,
 const atl::Optional<bool> inExposureAuto,
 const atl::Optional<int> inGamma,
 const atl::Optional<int> inSharpness,
 const atl::Optional<int> inFocus,
 avl::Image& outImage,
 atl::int64& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ICImagingControlState&			Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&		NIL	Serial number, display name, unique name or base name of the camera
	inInputQueueSize	int	1 – +∞	3	
	inPixelFormat	const ICImagingControlColorFormat::Type		BGR8	Pixel format
	inBinning	const Optional<int>	2 – 64	NIL	Skipping factor
	inSkipping	const Optional<int>	2 – 64	NIL	Binning factor
	inRoi	const Optional<Box>		NIL	Hardware Region of Interest
	inFrameRate	const Optional<float>	0.5 – ∞	NIL	Camera frame rate
	inGain	const Optional<int>	0 – +∞	NIL	Gain value
	inGainAuto	const Optional<bool>		NIL	Enable auto gain
	inExposure	const Optional<double>	0.0D – ∞	NIL	Exposure time
	inExposureAuto	const Optional<bool>		NIL	Enable auto exposure
	inGamma	const Optional<int>	0 – +∞	NIL	Gamma value
	inSharpness	const Optional<int>	0 – +∞	NIL	Sharpness value
	inFocus	const Optional<int>	0 – +∞	NIL	Focus value
	outImage	Image&			Captured frame
	outFrameID	int64&			Captured frame ID

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. To work with the IC Imaging Control 4 SDK you need to install the SDK on the target machine or copy manually the ic4core.dll file from the SDK installation directory (typically IC Imaging Control 4\bin\x64\) to the Aurora Vision Studio directory in Program Files. Alternatively, set the IC4PATH environment variable to the SDK installation directory.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, the first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- serial number,
- display name,
- unique name,
- base name of the camera.

Camera parameters

Most of the parameters exposed by camera filters are optional, setting them to *Auto* leaves related parameter for automatic configuration by the camera driver.

To change other and more advanced camera parameters, use the VCD Property Inspector available with ICImagingControl SDK. Refer to SDK documentation for information about parameters and how to save them into memory channels.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

ICImagingControl_SetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a boolean parameter of the camera.

Syntax

```
void avl::ICImagingControl_SetBoolParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inParameterName	const String&		Name of the parameter
	inValue	bool		Value of the parameter

Description

Sets a boolean parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

ICImagingControl_SetDigitalOutputState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital IO line state.

Syntax

```
void avl::ICImagingControl_SetDigitalOutputState
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 bool inOutputState
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inOutputState	bool		Digital output state

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. To work with the IC Imaging Control 4 SDK you need to install the SDK on the target machine or copy manually the ic4core.dll file from the SDK installation directory (typically IC Imaging Control 4\bin\x64\) to the Aurora Vision Studio directory in Program Files. Alternatively, set the IC4PATH environment variable to the SDK installation directory.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, the first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- serial number,
- display name,
- unique name,
- base name of the camera.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICImagingControl_GetDigitalIOState – Gets digital IO lines state.
- ICImagingControl_EnableExternalTrigger – Controls camera external trigger.
- ICImagingControl_GrabImage – Captures a frame from The Imaging Source cameras using ICImagingControl.

ICImagingControl_SetDoubleParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a double parameter of the camera.

Syntax

```
void avl::ICImagingControl_SetDoubleParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inParameterName	const String&		Name of the parameter
	inValue	double		Value of the parameter

Description

Sets a double-precision floating-point parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. To work with the IC Imaging Control 4 SDK you need to install the SDK on the target machine or copy manually the ic4core.dll file from the SDK installation directory (typically IC Imaging Control 4\bin\x64\) to the Aurora Vision Studio directory in Program Files. - ICImagingControl_SetBoolParameter – Sets a boolean parameter of the camera.
- ICImagingControl_GetDoubleParameter – Gets a double parameter of the camera.

ICImagingControl_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an enumeration parameter of the camera.

Syntax

```
void avl::ICImagingControl_SetEnumParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inParameterName	const String&		Name of the parameter
	inValue	const String&		Enumeration entry name

Description

Sets an enumeration parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface. The value is specified as the enumeration entry name string.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. ICImagingControl_SetLongParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an integer parameter of the camera.

Syntax

```
void avl::ICImagingControl_SetLongParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 atl::sint64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inParameterName	const String&		Name of the parameter
	inValue	sint64		Value of the parameter

Description

Sets an integer (64-bit) parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. - ICImagingControl_GetLongParameter – Gets an integer parameter of the camera.

ICImagingControl_SetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a string parameter of the camera.

Syntax

```
void avl::ICImagingControl_SetStringParameter
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera
	inParameterName	const String&		Name of the parameter
	inValue	const String&		Value of the parameter

Description

Sets a string parameter of The Imaging Source camera by name using the IC Imaging Control 4 GenICam property interface.

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

- ICImagingControl_GetStringParameter – Gets a string parameter of the camera.

ICImagingControl_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::ICImagingControl_StartAcquisition
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID,
 int inInputQueueSize,
 const avl::ICImagingControlColorFormat::Type inPixelFormat,
 const atl::Optional<int> inBinning,
 const atl::Optional<int> inSkipping,
 const atl::Optional<avl::Box> inRoi,
 const atl::Optional<float> inFrameRate,
 const atl::Optional<int> inGain,
 const atl::Optional<bool> inGainAuto,
 const atl::Optional<double> inExposure,
 const atl::Optional<bool> inExposureAuto,
 const atl::Optional<int> inGamma,
 const atl::Optional<int> inSharpness,
 const atl::Optional<int> inFocus
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ICImagingControlState&			Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&		NIL	Serial number, display name, unique name or base name of the camera
	inInputQueueSize	int	1 – +∞	3	
	inPixelFormat	const ICImagingControlColorFormat::Type		BGR8	Pixel format
	inBinning	const Optional<int>	2 – 64	NIL	Skipping factor
	inSkipping	const Optional<int>	2 – 64	NIL	Binning factor
	inRoi	const Optional<Box>		NIL	Hardware Region of Interest
	inFrameRate	const Optional<float>	0.5 – ∞	NIL	Camera frame rate
	inGain	const Optional<int>	0 – +∞	NIL	Gain value
	inGainAuto	const Optional<bool>		NIL	Enable auto gain
	inExposure	const Optional<double>	0.0D – ∞	NIL	Exposure time
	inExposureAuto	const Optional<bool>		NIL	Enable auto exposure
	inGamma	const Optional<int>	0 – +∞	NIL	Gamma value
	inSharpness	const Optional<int>	0 – +∞	NIL	Sharpness value
	inFocus	const Optional<int>	0 – +∞	NIL	Focus value

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install IC Imaging Control 4 SDK software.

Proper camera drivers and IC Imaging Control 4 SDK can be downloaded from the following website: https://www.theimagingsource.com/en-us/support/download/. To work with the IC Imaging Control 4 SDK you need to install the SDK on the target machine or copy manually the ic4core.dll file from the SDK installation directory (typically IC Imaging Control 4\bin\x64\) to the Aurora Vision Studio directory in Program Files. Alternatively, set the IC4PATH environment variable to the SDK installation directory.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, the first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- serial number,
- display name,
- unique name,
- base name of the camera.

Camera parameters

Most of the parameters exposed by camera filters are optional, setting them to *Auto* leaves related parameter for automatic configuration by the camera driver.

To change other and more advanced camera parameters, use the VCD Property Inspector available with ICImagingControl SDK. Refer to SDK documentation for information about parameters and how to save them into memory channels.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICImagingControl_GrabImage – Captures a frame from The Imaging Source cameras using ICImagingControl.
- ICImagingControl_GrabImage_WithTimeout – Captures a frame from The Imaging Source cameras using ICImagingControl.
- ICImagingControl_GetDigitalIOState – Gets digital IO lines state.
- ICImagingControl_SetDigitalOutputState – Sets digital IO line state.
- ICImagingControl_EnableExternalTrigger – Controls camera external trigger.

ICImagingControl_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::ICImagingControl_StopAcquisition
(
 ICImagingControlState& ioState,
 const atl::Optional<const atl::String&>& inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICImagingControlState&		Object used to maintain state of the function.
	inDeviceID	const Optional<const String&>&	NIL	Serial number, display name, unique name or base name of the camera

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

173. NET ICube

Table of content:

- ICube_GenerateSoftwareTrigger
- ICube_GrabImage
- ICube_GrabImage_WithTimeout
- ICube_SetParamAuto
- ICube_SetParameter
- ICube_SetParamOnePush
- ICube_SetTriggerMode
- ICube_StartAcquisition
- ICube_StopAcquisition

ICube_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger in ICube device.

Syntax

```
void avl::ICube_GenerateSoftwareTrigger
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICube_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Index of a camera

Description

Generates software trigger. This filter executes the ICubeSDK_SetTrigger(camIndex, TRIG_SW_DO) ICube SDK function.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

The full description of the camera parameters can be found in the ICube SDK documentation.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICube_GrabImage – Captures an image from an ICube camera.
- ICube_GrabImage_WithTimeout – Captures an image from an ICube camera; returns Nil if no frame comes in the specified time.
- ICube_SetParameter – Sets a parameter of type Integer in an ICube device.
- ICube_SetTriggerMode – Sets a trigger mode in an ICube device.
- ICube_SetParamAuto – Sets a parameter of type auto in an ICube device.
- ICube_SetParamOnePush – Sets a parameter of type One Push in an ICube device.

ICube_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an ICube camera.

Syntax

```
bool avl::ICube_GrabImage
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 avl::ICubeGrabMode::Type inGrabbingMode,
 atl::Optional<avl::ICubeResolutionMode::Type> inResolutionMode,
 atl::Optional<avl::ICubeBinSkip::Type> inSkippingMode,
 atl::Optional<avl::ICubeBinSkip::Type> inBinningMode,
 atl::Optional<float> inExposureTime,
 atl::Optional<avl::Box> inRoi,
 avl::Image& outImage,
 int& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	ICube_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	0 – ∞	NIL	Index of a camera
→	inInputQueueSize	int	1 – 1000	10	
→	inGrabbingMode	ICubeGrabMode::Type			
→	inResolutionMode	Optional<ICubeResolutionMode::Type>		NIL	
→	inSkippingMode	Optional<ICubeBinSkip::Type>		NIL	
→	inBinningMode	Optional<ICubeBinSkip::Type>		NIL	
→	inExposureTime	Optional<float>	0.0 – ∞	NIL	
→	inRoi	Optional<Box>		NIL	Range of pixels to be processed
←	outImage	Image&			Captured frame
←	outFrameID	int&			Captured frame ID

Description

All the Auto parameters (those with checkboxes in the Property window) are initially set to the default values of the camera (they are initially not changed by Aurora Vision Studio). You can modify them by checking a checkbox and entering your own value.

Add DLL path to system environment variable may be required.

Recommended ICube version for usage with Aurora Vision Studio is **2.0.5.1**.

Changing parameters **inGrabbingMode** and **inResolutionMode** requires restarting acquisition. It is time consuming and shouldn't be done in each iteration.

The **inDeviceID** parameter is set only once when the filter is executed for the first time (if it is set to Auto, the first available camera in the system will be used). All the other parameters are set during the first filter execution or when the parameter is changed (they are not set in every iteration when the value is not changed).

To set more complex parameters, please use one of the following filters: ICube_SetParameter, ICube_SetParamAuto, ICube_SetParamOnePush, ICube_SetTriggerMode. Please note that if you set some parameter value in the ICube_GrabImage filter you should not modify it in any other ICube filter – it may lead to problems.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

The full description of the camera parameters can be found in the ICube documentation.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICube_GrabImage_WithTimeout – Captures an image from an ICube camera; returns Nil if no frame comes in the specified time.

ICube_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an ICube camera; returns Nil if no frame comes in the specified time.

Syntax

```
bool avl::ICube_GrabImage_WithTimeout
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 avl::ICubeGrabMode::Type inGrabbingMode,
 int inTimeout,
 atl::Optional<avl::ICubeResolutionMode::Type> inResolutionMode,
 atl::Optional<avl::ICubeBinSkip::Type> inSkippingMode,
 atl::Optional<avl::ICubeBinSkip::Type> inBinningMode,
 atl::Optional<float> inExposureTime,
 atl::Optional<avl::Box> inRoi,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<int>& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	ICube_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	0 – ∞	NIL	Index of a camera
→	inInputQueueSize	int	1 – 1000	10	
→	inGrabbingMode	ICubeGrabMode::Type			
→	inTimeout	int	0 – ∞	100	Maximum time to wait for frame in milliseconds
→	inResolutionMode	Optional<ICubeResolutionMode::Type>		NIL	
→	inSkippingMode	Optional<ICubeBinSkip::Type>		NIL	
→	inBinningMode	Optional<ICubeBinSkip::Type>		NIL	
→	inExposureTime	Optional<float>	0.0 – ∞	NIL	
→	inRoi	Optional<Box>		NIL	Range of pixels to be processed
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int>&			Captured frame ID

Description

All the Auto parameters (those with checkboxes in the Property window) are initially set to the default values of the camera (they are initially not changed by Aurora Vision Studio). You can modify them by checking a checkbox and entering your own value.

Add DLL path to system environment variable may be required.

Recommended ICube version for usage with Aurora Vision Studio is **2.0.5.1**.

Changing parameters **inGrabbingMode** and **inResolutionMode** requires restarting acquisition. It is time consuming and shouldn't be done in each iteration.

The **inDeviceID** parameter is set only once when the filter is executed for the first time (if it is set to Auto, the first available camera in the system will be used). All the other parameters are set during the first filter execution or when the parameter is changed (they are not set in every iteration when the value is not changed).

To set more complex parameters, please use one of the following filters: ICube_SetParameter, ICube_SetParamAuto, ICube_SetParamOnePush, ICube_SetTriggerMode. Please note that if you set some parameter value in the ICube_GrabImage filter you should not modify it in any other ICube filter - it may lead to problems.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

The full description of the camera parameters can be found in the ICube documentation.

ICube_SetParamAuto

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type auto in an ICube device.

Syntax

```
void avl::ICube_SetParamAuto
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inType,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICube_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Index of a camera
	inType	int		Type of the parameter to set (see Parameter Definitions in the API Header)
	inValue	bool		1 == set auto, 0 == unset auto.

Description

If auto mode is supported, this filter sets/unsets auto mode of the parameter specified by **inType**. It executes the ICubeSDK_SetParamAuto ICube SDK function.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

ICube_SetParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Integer in an ICube device.

Syntax

```
void avl::ICube_SetParameter
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inType,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICube_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Index of a camera
	inType	int		Type of the parameter to set (see Parameter Definitions in the API Header)
	inValue	int		Value to set

Description

Sets value of the parameter specified by **inType**. This filter executes the ICubeSDK_SetCamParameter ICube SDK function.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

The full description of the camera parameters can be found in the ICube SDK documentation.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- ICube_GrabImage – Captures an image from an ICube camera.
- ICube_GrabImage_WithTimeout – Captures an image from an ICube camera; returns Nil if no frame comes in the specified time.
- ICube_SetTriggerMode – Sets a trigger mode in an ICube device.
- ICube_GenerateSoftwareTrigger – Generates software trigger in ICube device.
- ICube_SetParamAuto – Sets a parameter of type auto in an ICube device.
- ICube_SetParamOnePush – Sets a parameter of type One Push in an ICube device.

ICube_SetParamOnePush

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type One Push in an ICube device.

Syntax

```
void avl::ICube_SetParamOnePush
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inType
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICube_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Index of a camera
	inType	int		Type of the parameter to set (see Parameter Definitions in the API Header)

Description

If one push mode is supported, this filter sets/unsets one push mode of the parameter specified by **inType**. This filter executes the ICubeSDK_SetParamOnePush ICube SDK function.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

Please make sure that the ICube SDK is installed properly on your computer. To verify the driver installation, you can run iControl.exe. If the camera was detected and you can see the image from it in this application, you can use your ICube camera in Aurora Vision Studio.

Recommended ICube SDK version for Aurora Vision Studio usage is **v2.0.4.8**.

ICube_SetTriggerMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a trigger mode in an ICube device.

Syntax

```
void avl::ICube_SetTriggerMode
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::ICubeTriggerMode::Type inTriggerMode
)
```

Parameters

	Name	Type	Default	Description
	ioState	ICube_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Index of a camera
	inTriggerMode	ICubeTriggerMode::Type		Type of trigger mode (see Parameter Definitions in the API Header)

Description

Sets camera Trigger mode.

Remarks

To be able to use an ICube camera, you need to install the camera driver. You can find it at the following address (select binaries):

https://net-gmbh.com/en/machine-vision/products/cameras/usb2-icube/ or https://net-gmbh.com/en/machine-vision/products/cameras/usb3-vision-3icube/

ICube_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::ICube_StartAcquisition
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 avl::ICubeGrabMode::Type inGrabbingMode,
 atl::Optional<avl::ICubeResolutionMode::Type> inResolutionMode,
 atl::Optional<avl::ICubeBinSkip::Type> inSkippingMode,
 atl::Optional<avl::ICubeBinSkip::Type> inBinningMode,
 atl::Optional<float> inExposureTime,
 atl::Optional<avl::Box> inRoi
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ICube_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	0 – ∞	NIL	Index of a camera
	inInputQueueSize	int	1 – 1000	10	
	inGrabbingMode	ICubeGrabMode::Type			
	inResolutionMode	Optional<ICubeResolutionMode::Type>		NIL	
	inSkippingMode	Optional<ICubeBinSkip::Type>		NIL	
	inBinningMode	Optional<ICubeBinSkip::Type>		NIL	
	inExposureTime	Optional<float>	0.0 – ∞	NIL	
	inRoi	Optional<Box>		NIL	Range of pixels to be processed

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ICube_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::ICube_StopAcquisition
(
 ICube_State& ioState,
 atl::Optional<int> inDeviceID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ICube_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	0 – ∞	NIL	Index of a camera

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

174. IDS

Table of content:

- IDS_CaptureStatus
- IDS_ConfigureGPIO
- IDS_ForceTrigger
- IDS_GrabImage
- IDS_GrabImage_WithTimeout
- IDS_LoadParameterSet
- IDS_SetParameters
- IDS_StartAcquisition
- IDS_StopAcquisition

Also in AVL Lite

IDS_CaptureStatus

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

The function returns information on errors that occurred during an image capture. All errors are listed that occurred since the last reset of the function.

Syntax

```
void avl::IDS_CaptureStatus
(
 IDS_BaseState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 bool inReset,
 int& outNumberOfErrors,
 int& outNoDestMem,
 int& outConversionFailed,
 int& outImageLocked,
 int& outOutOfBuffers,
 int& outDeviceNotReady,
 int& outUsbTransferFailed,
 int& outDevTimeout,
 int& outEthBufferOverrun,
 int& outEthDevMissedImages,
 int& outFrameCaptureFailed
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	IDS_BaseState&		Object used to maintain state of the function.
→	inDeviceID	const Optional<String>&	NIL	Device serial number or user definable camera ID
→	inReset	bool		Resets the CaptureStatus information
←	outNumberOfErrors	int&		Total number of errors
←	outNoDestMem	int&		There is no destination memory for copying the finished image.
←	outConversionFailed	int&		The current image could not be processed correctly.
←	outImageLocked	int&		The destination buffers are locked and could not be written to.
←	outOutOfBuffers	int&		No free internal image memory is available to the driver. The image was discarded.
←	outDeviceNotReady	int&		The camera is no longer available. It is not possible to access images that have already been transferred.
←	outUsbTransferFailed	int&		The image was not transferred over the USB bus.
←	outDevTimeout	int&		The maximum allowable time for image capturing in the camera was exceeded.
←	outEthBufferOverrun	int&		The sensor transfers more data than the internal camera memory of the GigE uEye camera can accommodate.
←	outEthDevMissedImages	int&		Freerun mode: The camera could neither process nor output an image captured by the sensor. Hardware trigger mode : The camera received a hardware trigger signal which could not be processed because the sensor was still busy.
←	outFrameCaptureFailed	int&		USB 3 uEye CP Rev. 2 with activated image memory only: The image was not transferred.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

IDS_ConfigureGPIO

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures digital inputs/outputs of IDS camera.

Syntax

```
void avl::IDS_ConfigureGPIO
(
 IDS_BaseState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 int inGPIO,
 avl::IDSGPIOConfiguration::Type inConfiguration,
 bool inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	IDS_BaseState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Device serial number or user definable camera ID
	inGPIO	int	1 - 6		GPIO id
	inConfiguration	IDSGPIOConfiguration::Type			GPIO Configuration
	inState	bool			GPIO state (true = High, false = Low)

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install IDS SDK software.

IDS SDK can be downloaded from the following website: https://en.ids-imaging.com/downloads.html

To verify the driver installation, you can run IDS Camera Manager. If the camera was detected and you can see the view from the camera, you can use IDS SDK in Aurora Vision Studio.

Recommended IDS SDK version for Aurora Vision Studio usage is **4.96.1**.

Camera identification

When there is only one IDS camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to device serial number or user definable camera ID.

Source code

In Professional edition this filter is open source. You can use this filter as reference when implementing support for your specific hardware. You can also modify this filter and add some additional functionality.

The source code is located in the directory:

```
Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Typically it is:

```
C:\Users\Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- IDS_GrabImage - Captures an image from an IDS camera.
- IDS_GrabImage_WithTimeout - Captures an image from an IDS camera.
- IDS_StartAcquisition - Initialize2s and starts image acquisition in a camera.
- IDS_LoadParameterSet - Loads specific camera parameters.

Also in AVL Lite

IDS_ForceTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Forces software-controlled captures of an image while a capturing process triggered by hardware is in progress.

Syntax

```
void avl::IDS_ForceTrigger
(
 IDS_BaseState& ioState,
 const atl::Optional<atl::String>& inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	IDS_BaseState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Device serial number or user definable camera ID

- IDS_GrabImage – Captures an image from an IDS camera.
- IDS_GrabImage_WithTimeout – Captures an image from an IDS camera.
- IDS_StartAcquisition – Initialize2s and starts image acquisition in a camera.
- IDS_ForceTrigger – Forces software-controlled captures of an image while a capturing process triggered by hardware is in progress.

Also in AVL Lite

IDS_SetParameters

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets camera parameters.

Syntax

```
void avl::IDS_SetParameters
(
 IDS_BaseState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::Optional<avl::Box>& inAoi,
 const atl::Optional<float>& inFrameRate,
 const atl::Optional<float>& inExposureTime,
 const atl::Optional<avl::IDSBinning::Type>& inHorizontalBinning,
 const atl::Optional<avl::IDSBinning::Type>& inVerticalBinning,
 const atl::Optional<avl::IDSMirror::Type>& inMirror,
 const atl::Optional<bool>& inAutoBlackLevel,
 const atl::Optional<int>& inBlackLevelOffset,
 const atl::Optional<int>& inGamma,
 const atl::Optional<bool>& inGainBoost,
 const atl::Optional<int>& inGainMaster,
 const atl::Optional<int>& inGainRed,
 const atl::Optional<int>& inGainGreen,
 const atl::Optional<int>& inGainBlue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	IDS_BaseState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Device serial number or user definable camera ID
	inAoi	const Optional<Box>&		NIL	Required fragment of image to stream
	inFrameRate	const Optional<float>&	0.1 – 400.0	NIL	Frame rate
	inExposureTime	const Optional<float>&	0.0 – ∞	NIL	Exposure time in microseconds
	inHorizontalBinning	const Optional<IDSBinning::Type>&		NIL	Horizontal binning
	inVerticalBinning	const Optional<IDSBinning::Type>&		NIL	Vertical binning
	inMirror	const Optional<IDSMirror::Type>&		NIL	Mirror effect
	inAutoBlackLevel	const Optional<bool>&		NIL	Enable auto black level
	inBlackLevelOffset	const Optional<int>&	0 – ∞	NIL	Black level offset
	inGamma	const Optional<int>&	1 – 1000	NIL	Set gamma value
	inGainBoost	const Optional<bool>&		NIL	Set gain boost mode
	inGainMaster	const Optional<int>&	0 – 100	NIL	Set gain master value
	inGainRed	const Optional<int>&	0 – 100	NIL	Set gain red value
	inGainGreen	const Optional<int>&	0 – 100	NIL	Set gain green value
	inGainBlue	const Optional<int>&	0 – 100	NIL	Set gain blue value

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install IDS SDK software.

IDS SDK can be downloaded from the following website: https://en.ids-imaging.com/downloads.html

To verify the driver installation, you can run IDS Camera Manager. If the camera was detected and you can see the view from the camera, you can use IDS SDK in Aurora Vision Studio.

Recommended IDS SDK version for Aurora Vision Studio usage is **4.96.1**.

Camera identification

When there is only one IDS camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to device serial number or user definable camera ID.

Source code

In Professional edition this filter is open source. You can use this filter as reference when implementing support for your specific hardware. You can also modify this filter and add some additional functionality.

The source code is located in the directory:

```
Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Typically it is:

```
C:\Users\Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- IDS_GrabImage – Captures an image from an IDS camera.
- IDS_GrabImage_WithTimeout – Captures an image from an IDS camera.
- IDS_StartAcquisition – Initialize2s and starts image acquisition in a camera.
- IDS_ForceTrigger – Forces software-controlled captures of an image while a capturing process triggered by hardware is in progress.

Also in AVL Lite

IDS: IDS_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initialize2s and starts image acquisition in a camera.

Syntax

```
void avl::IDS_StartAcquisition
(
 IDS_BaseState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::String& inPixelFormat,
 int inInputQueueSize,
 bool inAutoReconnect,
 const atl::Optional<avl::IDSTriggerMode::Type>& inTriggerMode,
 const atl::Optional<avl::Box>& inAoi,
 const atl::Optional<float>& inFrameRate,
 const atl::Optional<float>& inExposureTime,
 const atl::Optional<avl::IDSBinning::Type>& inHorizontalBinning,
 const atl::Optional<avl::IDSBinning::Type>& inVerticalBinning,
 const atl::Optional<avl::IDSMirror::Type>& inMirror,
 const atl::Optional<bool>& inAutoBlackLevel,
 const atl::Optional<int>& inBlackLevelOffset,
 const atl::Optional<int>& inGamma,
 const atl::Optional<bool>& inGainBoost,
 const atl::Optional<int>& inGainMaster,
 const atl::Optional<int>& inGainRed,
 const atl::Optional<int>& inGainGreen,
 const atl::Optional<int>& inGainBlue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	IDS_BaseState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Device serial number or user definable camera ID
	inPixelFormat	const String&		\"Mono8\"	Pixel format. Supported values: Raw8, Mono8, Rgb8, Bgr8, Rgba8, Bgra8
	inInputQueueSize	int	1 – ∞	3	Capacity of input frames queue
	inAutoReconnect	bool		True	Automatically reconnect with the camera
	inTriggerMode	const Optional<IDSTriggerMode::Type>&		NIL	Camera trigger mode
	inAoi	const Optional<Box>&		NIL	Required fragment of image to stream
	inFrameRate	const Optional<float>&	0.1 – 400.0	NIL	Frame rate
	inExposureTime	const Optional<float>&	0.0 – ∞	NIL	Exposure time in microseconds
	inHorizontalBinning	const Optional<IDSBinning::Type>&		NIL	Horizontal binning
	inVerticalBinning	const Optional<IDSBinning::Type>&		NIL	Vertical binning
	inMirror	const Optional<IDSMirror::Type>&		NIL	Mirror effect
	inAutoBlackLevel	const Optional<bool>&		NIL	Enable auto black level
	inBlackLevelOffset	const Optional<int>&	0 – ∞	NIL	Black level offset
	inGamma	const Optional<int>&	1 – 1000	NIL	Set gamma value
	inGainBoost	const Optional<bool>&		NIL	Set gain boost mode
	inGainMaster	const Optional<int>&	0 – 100	NIL	Set gain master value
	inGainRed	const Optional<int>&	0 – 100	NIL	Set gain red value
	inGainGreen	const Optional<int>&	0 – 100	NIL	Set gain green value
	inGainBlue	const Optional<int>&	0 – 100	NIL	Set gain blue value

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install IDS SDK software.

IDS SDK can be downloaded from the following website: https://en.ids-imaging.com/downloads.html

To verify the driver installation, you can run IDS Camera Manager. If the camera was detected and you can see the view from the camera, you can use IDS SDK in Aurora Vision Studio.

Recommended IDS SDK version for Aurora Vision Studio usage is **4.96.1**.

Camera identification

When there is only one IDS camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to device serial number or user definable camera ID.

Source code

In Professional edition this filter is open source. You can use this filter as reference when implementing support for your specific hardware. You can also modify this filter and add some additional functionality.

```
Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Typically it is:

```
C:\Users\Public Documents\Aurora Vision Studio 5.x Professional\Sources\UserFilters\IDS
```

Working with camera

If you work with USB cameras then parameter **inAutoReconnect** doesn't work. Camera disconnection also can't be detected. To enable these features in USB cameras please add new register key:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\ueye\Parameters
DWORD DevChangeHandlerMode = 1
```

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Table of content:

- IFM_GrabImage
- IFM_GrabImage_WithTimeout
- IFM_SetDigitalOutput
- IFM_SetIntegrationTime
- IFM_SourceCommand
- IFM_StartAcquisition

IFM_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an ifm device.

Syntax

```
bool avl::IFM_GrabImage
(
 Ifm_State& ioState,
 const avl::IFMCameraAddress& inAddress,
 bool inGrab3dCoordinates,
 const atl::Optional<float>& inFrameRate,
 const atl::Optional<avl::IFMResolution::Type>& inResolution,
 const atl::Optional<avl::IFMTriggerMode::Type>& inTriggerMode,
 avl::Image& outDistancesImage,
 avl::Image& outAmplitudeImage,
 atl::Array<avl::Region>& outInvalidRois,
 atl::Conditional<avl::Point3DGrid>& out3dCoordinates
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Ifm_State&			Object used to maintain state of the function.
	inAddress	const IFMCameraAddress&			Device identifying address
	inGrab3dCoordinates	bool			Enable 3d coordinates capturing
	inFrameRate	const Optional<float>&	0.017 – 300.0	NIL	Sets the target frame rate in fps at which device should capture images
	inResolution	const Optional<IFMResolution::Type>&		NIL	Sets the resolution of output image
	inTriggerMode	const Optional<IFMTriggerMode::Type>&		NIL	Sets the trigger mode on device for capturing image
	outDistancesImage	Image&			Captured distance image
	outAmplitudeImage	Image&			Captured amplitude image
	outInvalidRois	Array<Region>&			Region array with invalid pixels: INVALID, SATURATED, INCONSISTENT and LOW_SIGNAL.
	out3dCoordinates	Conditional<Point3DGrid>&			Captured 3d coordinates

Remarks

Device driver software

This filter is intended to cooperate with a device using PMDSDK 2. In order to connect with the device, it is required to download PMDSDK 2.

PMDSDK 2 can be downloaded from the following website: https://www.ifm.com/us/en/search#!/infomaterialanddownloads?_type=infomaterialanddownloads&docType=download. Please download "O3D303 Software Development Kit"

After download you have to manually copy pmdaccess2.dll file to Aurora Vision Studio main directory (usually located in Program Files). Alternatively you can add directory with this dll file to PATH environment variable

Additionally in **inAddress** input you will need to provide camera plugin and processing plugin file path.

It is recommended to disable DHCP in the device and using static IP address.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- IFM_GrabImage_WithTimeout – Captures an image from an ifm device.
- IFM_SourceCommand – Issues a device-dependent command.
- IFM_SetIntegrationTime – Sets the integration time of the device.
- IFM_StartAcquisition – Initializes and starts image acquisition in a device.
- IFM_SetDigitalOutput – Sets the logic state of a specific io.

IFM_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an ifm device.

Syntax

```
bool avl::IFM_GrabImage_WithTimeout
(
 Ifm_State& ioState,
 const avl::IFMCameraAddress& inAddress,
 int inTimeout,
 bool inGrab3dCoordinates,
 const atl::Optional<float>& inFrameRate,
 const atl::Optional<avl::IFMResolution::Type>& inResolution,
 const atl::Optional<avl::IFMTriggerMode::Type>& inTriggerMode,
 atl::Conditional<avl::Image>& outDistancesImage,
 atl::Conditional<avl::Image>& outAmplitudeImage,
 atl::Conditional<atl::Array<avl::Region>>& outInvalidRois,
 atl::Conditional<avl::Point3DGrid>& out3dCoordinates
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Ifm_State&			Object used to maintain state of the function.
→	inAddress	const IFMCameraAddress&			Device identifying address
→	inTimeout	int	0 – ∞	100	Maximum time to wait for frame in milliseconds
→	inGrab3dCoordinates	bool			Enable 3d coordinates capturing
→	inFrameRate	const Optional<float>&	0.017 – 300.0	NIL	Sets the target frame rate in fps at which device should capture images
→	inResolution	const Optional<IFMResolution::Type>&		NIL	Sets the resolution of output image
→	inTriggerMode	const Optional<IFMTriggerMode::Type>&		NIL	Sets the trigger mode on device for capturing image
←	outDistancesImage	Conditional<Image>&			Captured distance image
←	outAmplitudeImage	Conditional<Image>&			Captured amplitude image
←	outInvalidRois	Conditional<Array<Region>>&			Region array with invalid pixels: INVALID, SATURATED, INCONSISTENT and LOW_SIGNAL.
←	out3dCoordinates	Conditional<Point3DGrid>&			Captured 3d coordinates

- IFM_SetDigitalOutput – Sets the logic state of a specific io.

IFM_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the logic state of a specific io.

Syntax

```
void avl::IFM_SetDigitalOutput
(
 Ifm_State& ioState,
 const avl::IFMCameraAddress& inAddress,
 const int inNumber,
 const bool inState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Ifm_State&		Object used to maintain state of the function.
	inAddress	const IFMCameraAddress&		Device identifying address
	inNumber	const int		Digital output number
	inState	const bool		Output state

Remarks

Device driver software

This filter is intended to cooperate with a device using PMDSDK 2. In order to connect with the device, it is required to download PMDSDK 2.

PMDSDK 2 can be downloaded from the following website: https://www.ifm.com/us/en/search#!/infomaterialanddownloads?_type=infomaterialanddownloads&docType=download. Please download "O3D303 Software Development Kit"

- IFM_StartAcquisition – Initializes and starts image acquisition in a device.

IFM_SetIntegrationTime

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the integration time of the device.

Syntax

```
void avl::IFM_SetIntegrationTime
(
 Ifm_State& ioState,
 const avl::IFMCameraAddress& inAddress,
 const int inIndex,
 const int inTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Ifm_State&			Object used to maintain state of the function.
	inAddress	const IFMCameraAddress&			Device identifying address
	inIndex	const int	0 – + ∞		Index of the integration time
	inTime	const int	0 – + ∞		Integration time in microseconds

IFM_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a device.

Syntax

```
void avl::IFM_StartAcquisition
(
 Ifm_State& ioState,
 const avl::IFMCameraAddress& inAddress,
 const atl::Optional<float>& inFrameRate,
 const atl::Optional<avl::IFMResolution::Type>& inResolution,
 const atl::Optional<avl::IFMTriggerMode::Type>& inTriggerMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Ifm_State&			Object used to maintain state of the function.
	inAddress	const IFMCameraAddress&			Device identifying address
	inFrameRate	const Optional<float>&	0.017 – 300.0	NIL	Sets the target frame rate in fps at which device should capture images
	inResolution	const Optional<IFMResolution::Type>&		NIL	Sets the resolution of output image
	inTriggerMode	const Optional<IFMTriggerMode::Type>&		NIL	Sets the trigger mode on device for capturing image

JAI_ExecuteCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes command

Syntax

```
void avl::JAI_ExecuteCommand
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inCommand
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inCommand	const String&		Parameter name

Also in AVL Lite

JAI_FindDevices

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Finds devices reachable from this system.

Syntax

```
void avl::JAI_FindDevices
(
 JAI_State& ioState,
 atl::Optional<int> inDetectionTimeout,
 atl::Array<avl::EBUSDeviceInfo>& outDevices
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	JAI_State&			Object used to maintain state of the function.
	inDetectionTimeout	Optional<int>	100 – 60000	NIL	Sets the time to search the system devices in ms.
	outDevices	Array<EBUSDeviceInfo>&			

Also in AVL Lite

JAI_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger.

Syntax

```
void avl::JAI_GenerateSoftwareTrigger
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

Also in AVL Lite

JAI_GetBooleanParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a boolean parameter of the JAI device.

Syntax

```
void avl::JAI_GetBooleanParameter
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	bool&		Parameter value

Also in AVL Lite

JAI_GetEnumParameterAsInteger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enum parameter of the JAI device.

Syntax

```
void avl::JAI_GetEnumParameterAsInteger
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		Parameter value

Also in AVL Lite

JAI_GetEnumParameterAsString

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enum parameter of the JAI device.

Syntax

```
void avl::JAI_GetEnumParameterAsString
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	String&		Parameter value

Also in AVL Lite

JAI_GetFloatParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a float parameter of the JAI device.

Syntax

```
void avl::JAI_GetFloatParameter
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	double&		Parameter value

Also in AVL Lite

JAI_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an integer parameter of the JAI device.

Syntax

```
void avl::JAI_GetIntegerParameter
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		Parameter value

Also in AVL Lite

JAI_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a string parameter of the JAI device.

Syntax

```
void avl::JAI_GetStringParameter
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	JAI_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying number
→	inName	const String&		Parameter name
←	outValue	String&		Parameter value

Also in AVL Lite

JAI_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using a JAI device.

Syntax

```
bool avl::JAI_GrabImage
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<avl::EBUSPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<avl::EBUSAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::EBUSAutoExposureMode::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<avl::EBUSAutoGainMode::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<avl::EBUSTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::EBUSTriggerActivation::Type> inTriggerActivation,
 bool inSkipInvalidFrames,
 bool inTryReconnection,
 avl::Image& outImage,
 avl::EBUSFrameData& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	JAI_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inPixelFormat	Optional<EBUSPixelFormat::Type>		NIL	Image pixel format
→	inAoi	Optional<const Box&>		NIL	Area of interest
→	inAcquisitionMode	Optional<EBUSAcquisitionMode::Type>		NIL	Acquisition mode
→	inAcquisitionFrameCount	Optional<int>	1 – 65535	NIL	Number of frames to acquire in MultiFrame acquisition mode
→	inFrameRate	Optional<double>	0.125D – ∞	NIL	Acquisition frame rate
→	inExposureAuto	Optional<EBUSAutoExposureMode::Type>		NIL	Automatic exposure mode
→	inExposureTime	Optional<double>	1.0D – ∞	NIL	Exposure time in us
→	inGainAuto	Optional<EBUSAutoGainMode::Type>		NIL	Automatic gain mode
→	inGain	Optional<double>	1.0D – ∞	NIL	Gain as an absolute physical value
→	inTriggerSource	Optional<EBUSTriggerSource::Type>		NIL	Trigger source
→	inTriggerActivation	Optional<EBUSTriggerActivation::Type>		NIL	Trigger activation mode
→	inSkipInvalidFrames	bool		True	Skipping invalid images
→	inTryReconnection	bool		True	Try to reconnect if the camera is disconnected
←	outImage	Image&			Captured frame
←	outFrameData	EBUSFrameData&			Captured frame data

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS SDK for JAI software with camera dedicated drivers.

eBUS SDK for JAI can be downloaded from the following website: https://www.jai.com/support-software/jai-software.

Recommended eBUS SDK for JAI version for Aurora Vision Studio usage is **6.5.3**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, the first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **Serial Number** – should be printed on the device housing.
- **Unique ID** – unique device identifier.
- **User defined name** – user defined device name.
- **GUID** – GUID of USB3Vision device.
- **IP Address** – network IP address of GigE device.
- **MAC Address** – MAC address of GigE device.

Camera parameters

To change other and more advanced internal camera parameters use the "eBUS Player for JAI" tool which could be installed with the eBUS SDK for JAI.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- JAI_StartAcquisition – Initializes and starts image acquisition in a camera.

JAI_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using a JAI device with timeout.

Syntax

```
bool avl::JAI_GrabImage_WithTimeout
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 int inInputQueueSize,
 atl::Optional<avl::EBUSPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<avl::EBUSAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::EBUSAutoExposureMode::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<avl::EBUSAutoGainMode::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<avl::EBUSTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::EBUSTriggerActivation::Type> inTriggerActivation,
 bool inSkipInvalidFrames,
 bool inTryReconnection,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<avl::EBUSFrameData>& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	JAI_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inTimeout	int	100 – ∞	100	Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inPixelFormat	Optional<EBUSPixelFormat::Type>		NIL	Image pixel format
→	inAoi	Optional<const Box&>		NIL	Area of interest
→	inAcquisitionMode	Optional<EBUSAcquisitionMode::Type>		NIL	Acquisition mode
→	inAcquisitionFrameCount	Optional<int>	1 – 65535	NIL	Number of frames to acquire in MultiFrame acquisition mode
→	inFrameRate	Optional<double>	0.125D – ∞	NIL	Acquisition frame rate

JAI_SetBooleanParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a boolean parameter of the JAI device.

Syntax

```
void avl::JAI_SetBooleanParameter
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	bool		Parameter value

Also in AVL Lite

JAI_SetEnumParameterAsInteger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an enum parameter of the JAI device.

Syntax

```
void avl::JAI_SetEnumParameterAsInteger
(
 JAI_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	JAI_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	int64		Parameter value

Add DLL path to system environment variable is required.

Use of connect filter is required before performing other operations.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- KontronGPIOBoard_Connect – Connect to Kontron GPIO board.
- KontronGPIOBoard_Disconnect – Disconnect from Kontron GPIO board.

KontronGPIOBoard_SetOutputState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets input level.

Syntax

```
void avl::KontronGPIOBoard_SetOutputState
(
 KontronGPIOBoard_State& ioState,
 int inPort,
 bool inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	KontronGPIOBoard_State&			Object used to maintain state of the function.
	inPort	int	1 - 8		
	inState	bool			

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install Kontron GPIO SDK.

Add DLL path to system environment variable is required.

Use of connect filter is required before performing other operations.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- KontronGPIOBoard_Connect - Connect to Kontron GPIO board.
- KontronGPIOBoard_Disconnect - Disconnect from Kontron GPIO board.

178. Lumenera

Table of content:

- Lumenera_GetParameter
- Lumenera_GpioConfigure
- Lumenera_GpioRead
- Lumenera_GpioSelect
- Lumenera_GpioWrite
- Lumenera_GrabImage
- Lumenera_GrabImage_WithTimeout
- Lumenera_SetParameter
- Lumenera_StartAcquisition
- Lumenera_StopAcquisition

Lumenera_GetParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter.

Syntax

```
void avl::Lumenera_GetParameter
(
 Lumenera_State& ioState,
 const atl::Optional<int>& inDeviceID,
 const avl::LumeneraProperties::Type inType,
 float& outParameter
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Lumenera_State&			Object used to maintain state of the function.
→	inDeviceID	const Optional<int>&	1 - 10000	NIL	Device identifying number
→	inType	const LumeneraProperties::Type			
←	outParameter	float&			

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Lumenera SDK software.

Lumenera SDK can be downloaded from the following website: https://www.lumenera.com/sdk.html

Recommended Lumenera SDK version for Aurora Vision Studio usage is 6.3.

Remember to install camera drivers from Lumenera SDK, in directory *%LUMENERA_SDK%\Redist*. The driver for USB is Redist LU, LM, LW, LC, LT, USB. The best is to use *All Driver Install*
Follow these instructions for quick install:

- open cmd.exe
- copy to opened window (enters driver directory):
  ```
  cd "%LUMENERA_SDK%\Redist\Redist LU, LM, LW, LC, LT, USB\All Driver Install"
  ```
- copy to opened window (installs the driver):
  - For 64 bit Windows
    ```
    luihlp64.exe -inf -dll -ax
    ```
  - For 32 bit Windows
    ```
    luihlp.exe -inf -dll -ax
    ```

Camera identification

When there is only one Lumenera camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- Lumenera_SetParameter - Sets a parameter.

Lumenera_GpioConfigure

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures pin direction, true for output.

Syntax

```
void avl::Lumenera_GpioConfigure
(
 Lumenera_State& ioState,
 const atl::Optional<int>& inDeviceID,
 const bool inGpio0,
 const bool inGpio1,
 const bool inGpio2,
 const bool inGpio3
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Lumenera_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>&	1 - 10000	NIL	Device identifying number
	inGpio0	const bool			
	inGpio1	const bool			
	inGpio2	const bool			
	inGpio3	const bool			

Remarks

GPIO pin identification

Some cameras enumerate pins starting from 1, so outGpi0 might be GPI1 and inGpo0 might be GPO1.
Similarly for other pins.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Lumenera SDK software.

Lumenera SDK can be downloaded from the following website: https://www.lumenera.com/sdk.html

Recommended Lumenera SDK version for Aurora Vision Studio usage is 6.3.

Remember to install camera drivers from Lumenera SDK, in directory *%LUMENERA_SDK%\Redist*. The driver for USB is Redist LU, LM, LW, LC, LT, USB. The best is to use *All Driver Install*
Follow these instructions for quick install:

- open cmd.exe
- copy to opened window (enters driver directory):

```
cd "%LUMENERA_SDK%\Redist\Redist LU, LM, LW, LC, LT, USB\All Driver Install"
```

- copy to opened window (installs the driver):
  - For 64 bit Windows

```
luihlp64.exe -inf -dll -ax
```

  - For 32 bit Windows

```
luihlp.exe -inf -dll -ax
```

Camera identification

When there is only one Lumenera camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- Lumenera_GpioRead – Reads GPI pins.
- Lumenera_GpioWrite – Writes GPO pins.
- Lumenera_GpioSelect – Selects GPO functionality, true for manual toggling using GpioWrite filter (see LucamGpoSelect in Lumenera API for default mode).

Lumenera_GpioRead

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads GPI pins.

Syntax

```
void avl::Lumenera_GpioRead
(
 Lumenera_State& ioState,
 const atl::Optional<int>& inDeviceID,
 bool& outGpi0,
 bool& outGpi1,
 bool& outGpi2,
 bool& outGpi3
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Lumenera_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>&	1 – 10000	NIL	Device identifying number
	outGpi0	bool&			
	outGpi1	bool&			
	outGpi2	bool&			
	outGpi3	bool&			

Remarks

GPIO pin identification

Some cameras enumerate pins starting from 1, so outGpi0 might be GPI1 and inGpo0 might be GPO1. Similarly for other pins.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Lumenera SDK software.

Lumenera SDK can be downloaded from the following website: https://www.lumenera.com/sdk.html

Recommended Lumenera SDK version for Aurora Vision Studio usage is 6.3.

Remember to install camera drivers from Lumenera SDK, in directory *%LUMENERA_SDK%\Redist*. The driver for USB is Redist LU, LM, LW, LC, LT, USB. The best is to use *All Driver Install*
Follow these instructions for quick install:

- Lumenera_GpioConfigure – Configures pin direction, true for output.
- Lumenera_GpioSelect – Selects GPO functionality, true for manual toggling using GpioWrite filter (see LucamGpoSelect in Lumenera API for default mode).

Lumenera_GpioSelect

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Selects GPO functionality, true for manual toggling using GpioWrite filter (see LucamGpoSelect in Lumenera API for default mode).

Syntax

```
void avl::Lumenera_GpioSelect
(
 Lumenera_State& ioState,
 const atl::Optional<int>& inDeviceID,
 const bool inGpio0,
 const bool inGpio1,
 const bool inGpio2,
 const bool inGpio3
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Lumenera_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>&	1 - 10000	NIL	Device identifying number
	inGpio0	const bool			
	inGpio1	const bool			
	inGpio2	const bool			
	inGpio3	const bool			

Remarks

Lumenera_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Lumenera.

Syntax

```
bool avl::Lumenera_GrabImage
(
 Lumenera_State& ioState,
 const atl::Optional<int> inDeviceID,
 const avl::LumeneraImageFormatParams& inImageFormat,
 const avl::LumeneraAcquisitionControlParams& inAcquisitionControl,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Lumenera_State&			Object used to maintain state of the function.
→	inDeviceID	const Optional<int>	1 – 10000	NIL	Device identifying number
→	inImageFormat	const LumeneraImageFormatParams&			Image format parameters
→	inAcquisitionControl	const LumeneraAcquisitionControlParams&			Acquisition control parameters
←	outImage	Image&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Lumenera SDK software.

Lumenera SDK can be downloaded from the following website: https://www.lumenera.com/sdk.html

 const avl::MicroviewAcquisitionParams& inAcquisitionControl,
 const avl::MicroviewTriggerParams& inTriggerControl,
 avl::Image& outImage,
 int& outFrameId
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Microview_State&			Object used to maintain state of the function.
→	inDeviceID	const Optional<int>	0 – 10000	NIL	Device identifying number
→	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
→	inJumboFrameSupport	bool		True	
→	inRescanNeeded	bool			
→	inUsersSettingsParams	const MicroviewUsersSettingsParams&			
→	inImageFormat	const MicroviewImageFormatParams&			
→	inAcquisitionControl	const MicroviewAcquisitionParams&			
→	inTriggerControl	const MicroviewTriggerParams&			
←	outImage	Image&			Captured frame
←	outFrameId	int&			Frame id

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install MVGESDK software with camera dedicated drivers.

MVGESDK can be downloaded from the following website: http://www.microview.com.cn (registration may be required).

Recommended MVGESDK version for Aurora Vision Studio usage is **2.8**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Device number** – should be specified on device casing.

Camera parameters

Setting **inJumboFrameSupport** parameter to 'true' will select maximum possible camera package size.

Setting **inRescanNeeded** parameter to 'true' will rescan network to search new cameras.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- Microview_StartAcquisition – Starts acquisition using Microview.

Also in AVL Lite

Microview_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures with timeout a frame using Microview.

Syntax

```
bool avl::Microview_GrabImage_WithTimeout
(
 Microview_State& ioState,
 const atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 bool inJumboFrameSupport,
 bool inRescanNeeded,
 const avl::MicroviewUsersSettingsParams& inUsersSettingsParams,
 const avl::MicroviewImageFormatParams& inImageFormat,
 const avl::MicroviewAcquisitionParams& inAcquisitionControl,
 const avl::MicroviewTriggerParams& inTriggerControl,
 const atl::Optional<int> inTimeout,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<int>& outFrameId
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Microview_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>	0 – 10000	NIL	Device identifying number
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inJumboFrameSupport	bool		True	
	inRescanNeeded	bool			
	inUsersSettingsParams	const MicroviewUsersSettingsParams&			
	inImageFormat	const MicroviewImageFormatParams&			
	inAcquisitionControl	const MicroviewAcquisitionParams&			
	inTriggerControl	const MicroviewTriggerParams&			
	inTimeout	const Optional<int>	1 – ∞	100	
	outImage	Conditional<Image>&			Captured frame
	outFrameId	Conditional<int>&			Frame id

Also in AVL Lite

Microview_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts acquisition using Microview.

Syntax

```
void avl::Microview_StartAcquisition
(
 Microview_State& ioState,
 const atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 bool inJumboFrameSupport,
 bool inRescanNeeded,
 const avl::MicroviewUsersSettingsParams& inUsersSettingsParams,
 const avl::MicroviewImageFormatParams& inImageFormat,
 const avl::MicroviewAcquisitionParams& inAcquisitionControl,
 const avl::MicroviewTriggerParams& inTriggerControl
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Microview_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>	0 – 10000	NIL	Device identifying number
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inJumboFrameSupport	bool		True	
	inRescanNeeded	bool			
	inUsersSettingsParams	const MicroviewUsersSettingsParams&			
	inImageFormat	const MicroviewImageFormatParams&			
	inAcquisitionControl	const MicroviewAcquisitionParams&			
	inTriggerControl	const MicroviewTriggerParams&			

Remarks

This filter is intended for establishing connection with a Microview camera device using MVGESDK interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of Microview_GrabImage or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. Microview_GrabImage or Microview_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install MVGESDK software with camera dedicated drivers.

MVGESDK can be downloaded from the following website: http://www.microview.com.cn (registration may be required).

Recommended MVGESDK version for Aurora Vision Studio usage is **2.8**.

Add DLL path to system environment variable may be required.

Microview_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops acquisition using Microview.

Syntax

```
void avl::Microview_StopAcquisition
(
 Microview_State& ioState,
 const atl::Optional<int> inDeviceID,
 bool inJumboFrameSupport,
 bool inRescanNeeded
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Microview_State&			Object used to maintain state of the function.
	inDeviceID	const Optional<int>	0 – 10000	NIL	Device identifying number
	inJumboFrameSupport	bool		True	
	inRescanNeeded	bool			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

180. MSSQL

Table of content:

- MSSQL_EndTransaction
- MSSQL_GetCommitMode
- MSSQL_Query
- MSSQL_Read
- MSSQL_SetCommitMode
- MSSQL_Write

MSSQL_EndTransaction

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Ends the ongoing transaction.

Syntax

```
void avl::MSSQL_EndTransaction
(
 MSSQL_State& ioState,
 const atl::String& inConnectionString,
 const avl::MSSQLCompletionType::Type& inCompletionType
)
```

Parameters

	Name	Type	Default	Description
	ioState	MSSQL_State&		Object used to maintain state of the function.
	inConnectionString	const String&		Connection string.
	inCompletionType	const MSSQLCompletionType::Type&		Transaction completion type (commit or rollback).

Description

Ending a transaction

This filter can be used to either commit or rollback the current transaction when the commit mode is set to manual.

Remarks

SQL database driver software

This filter is intended to cooperate with Microsoft SQL Server database. To be able to open a connection to the database, it is required to install Microsoft ODBC Driver for SQL Server.

Add DLL path to system environment variable may be required.

Recommended ODBC Driver version for Aurora Vision Studio usage is **18**.

Microsoft ODBC Driver for SQL Server can be downloaded from the following website:
https://learn.microsoft.com/en-us/sql/connect/odbc/download-odbc-driver-for-sql-server.

Connecting to a database

inConnectionString field must be used to enter a connection string that specifies information about a data source and the means of connecting to it. **inConnectionString** can be set to:

- **DSN=<DSN_name>**
  where DSN_name is a name of a User or System DSN configured using the Microsoft ODBC Data Source Administrator tool
- **FILEDSN=<DSN_file_path>**
  where DSN_file_path is a path to a .dsn file created using the Microsoft ODBC Data Source Administrator tool
- any other valid connection string, e.g.
  Driver={ODBC Driver 18 for SQL Server};Server=myServerAddress;Database=myDataBase;UID=myUsername;PWD=myPassword;

For more information about connection strings, see: https://www.connectionstrings.com/sql-server/.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

MSSQL_GetCommitMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the database commit mode.

Syntax

```
void avl::MSSQL_GetCommitMode
(
 MSSQL_State& ioState,
 const atl::String& inConnectionString,
 avl::MSSQLCommitMode::Type& outCommitMode
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	MSSQL_State&		Object used to maintain state of the function.
→	inConnectionString	const String&		Connection string.
←	outCommitMode	MSSQLCommitMode::Type&		Commit mode.

See Also

- MSSQL_SetCommitMode – Sets the database commit mode.

MSSQL_Query

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends a query to the database.

Syntax

```
void avl::MSSQL_Query
(
 MSSQL_State& ioState,
 const atl::String& inConnectionString,
 const atl::String& inQuery,
 bool inIncludeColumnTitles,
 atl::Array<atl::Array<atl::String>>& outData
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	MSSQL_State&		Object used to maintain state of the function.
→	inConnectionString	const String&		Connection string.
→	inQuery	const String&		SQL Query.
→	inIncludeColumnTitles	bool	False	Whether or not to include column names in the output data.
←	outData	Array<Array<String>>&		Data read as strings.

MSSQL_Read

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a value from the database.

Syntax

```
void avl::MSSQL_Read
(
 MSSQL_State& ioState,
 const atl::String& inConnectionString,
 const atl::String& inTableName,
 const atl::String& inColumnName,
 const atl::String& inQueriedColumn,
 const atl::String& inQueryValue,
 bool inIncludeColumnTitles,
 atl::Array<atl::Array<atl::String>>& outReadData
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	MSSQL_State&		Object used to maintain state of the function.
→	inConnectionString	const String&		Connection string.
→	inTableName	const String&		Name of the table to access.
→	inColumnName	const String&		Which column will be checked.
→	inQueriedColumn	const String&		Column name to compare.
→	inQueryValue	const String&		Value to compare.
→	inIncludeColumnTitles	bool	False	Whether or not to include column names in the output data.

MultiCam_GetDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reporting the logic state of I/O lines used as inputs.

Syntax

```
void avl::MultiCam_GetDigitalInput
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 int inInput,
 const atl::Optional<avl::MultiCamInputStyle::Type>& inInputStyle,
 avl::MultiCamInputState::Type& outState
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	MultiCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
→	inInput	int		Input pin index
→	inInputStyle	const Optional<MultiCamInputStyle::Type>&	NIL	Controlling the electrical style of I/O lines used as inputs. If Nil then lease style as it is
←	outState	MultiCamInputState::Type&		Returns the current logic state of I/O line

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install MultiCam SDK software. Currently Aurora Vision Studio requires **MultiCam version 6.18**.

MultiCam drivers can be downloaded from following website: https://www.euresys.com (registration may be required).

Supported frame grabbers:

- GRABLINK series
- DOMINO series
- Picolo series

Board identification

When there is only one board connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, first available board will be found and connected.

inDeviceID can be used to pick one of multiple boards connected to the computer. **inDeviceID** can be set to:

- board name,
- board identifier,
- driver index,
- pci position.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- MultiCam_SetDigitalOutput – Sets digital output.

MultiCam_GetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type integer from euresys device.

Syntax

```
void avl::MultiCam_GetIntegerParameter
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inConnector,
 avl::MultiCamDestinationClass::Type inDestinationClass,
 const atl::String& inName,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inConnector	Optional<String>	NIL	Connector
	inDestinationClass	MultiCamDestinationClass::Type		Class where the value should be set (board or channel)
	inName	const String&		Parameter name
	outValue	int&		Parameter value

Remarks

- driver index,
- pci position.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- MultiCam_GrabImage – Captures a frame using Euresys frame grabber.

MultiCam_GetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String from euresys device.

Syntax

```
void avl::MultiCam_GetStringParameter
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inConnector,
 avl::MultiCamDestinationClass::Type inDestinationClass,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	MultiCam_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
→	inConnector	Optional<String>	NIL	Connector
→	inDestinationClass	MultiCamDestinationClass::Type		Class where the value should be set (board or channel)
→	inName	const String&		Parameter name
←	outValue	String&		Parameter value

Remarks

Board driver software

This filter is intended to cooperate with board using its vendor SDK. To be able to connect with board it is required to install MultiCam SDK software. Currently Aurora Vision Studio requires **MultiCam version 6.18**.

MultiCam drivers can be downloaded from following website: https://www.euresys.com (registration may be required).

Supported frame grabbers:

- GRABLINK series
- DOMINO series
- Picolo series

Board identification

When there is only one board connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, first available board will be found and connected.

inDeviceID can be used to pick one of multiple boards connected to the computer. **inDeviceID** can be set to:

- board name,
- board identifier,
- driver index,
- pci position.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

MultiCam_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Euresys frame grabber.

Syntax

```
bool avl::MultiCam_GrabImage
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inTopology,
 atl::Optional<atl::String> inCameraTapConfiguration,
 const atl::String& inConnector,
 avl::MultiCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<const atl::File&> inCameraFile,
 atl::Optional<int> inPageLengthLn,
 avl::MultiCamColorFormat::Type inColorFormat,
 atl::Optional<int> inGain,
 atl::Optional<int> inSurfaceCount,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	MultiCam_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<String>		NIL	Board name, board identifier or serial number
→	inTopology	Optional<String>		NIL	Board topology
→	inCameraTapConfiguration	Optional<String>		NIL	Tap configuration of camera
→	inConnector	const String&			Indication of connector used by channel
→	inAcquisitionMode	MultiCamAcquisitionMode::Type			Acquisition Mode
→	inCameraFile	Optional<const File&>		NIL	Camera configuration file
→	inPageLengthLn	Optional<int>	1 – 65535	NIL	Page Length
→	inColorFormat	MultiCamColorFormat::Type			Color format
→	inGain	Optional<int>		NIL	Linear control of gain for all digitizing units
→	inSurfaceCount	Optional<int>	1 – 4096	3	Number of allocated surfaces
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Captured frame ID
←	outTimestamp	int64&			Captured frame timestamp in microseconds

MultiCam_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Euresys frame grabber.

Syntax

```
bool avl::MultiCam_GrabImage_WithTimeout
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inTopology,
 atl::Optional<int> inTimeout,
 atl::Optional<atl::String> inCameraTapConfiguration,
 const atl::String& inConnector,
 avl::MultiCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<const atl::File&> inCameraFile,
 atl::Optional<int> inPageLengthLn,
 avl::MultiCamColorFormat::Type inColorFormat,

MultiCam_LoadConfigurationFile

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Loads camera configuration file.

Syntax

```
void avl::MultiCam_LoadConfigurationFile
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inTopology,
 const atl::String& inConnector,
 atl::Optional<const atl::File&> inCameraFile
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inTopology	Optional<String>	NIL	Board topology
	inConnector	const String&		Indication of connector used by channel
	inCameraFile	Optional<const File&>	NIL	Camera configuration file

MultiCam_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital output.

Syntax

```
void avl::MultiCam_SetDigitalOutput
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 int inOutput,
 const atl::Optional<avl::MultiCamOutputStyle::Type>& inOutputStyle,
 avl::MultiCamOutputState::Type inOutputState
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inOutput	int		Output pin index
	inOutputStyle	const Optional<MultiCamOutputStyle::Type>&	NIL	Controlling the electrical style of I/O lines used as outputs. If Nil then lease style as it is
	inOutputState	MultiCamOutputState::Type		Issuing the logic state of I/O lines used as outputs

MultiCam_SetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type integer into euresys device.

Syntax

```
void avl::MultiCam_SetIntegerParameter
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inConnector,
 avl::MultiCamDestinationClass::Type inDestinationClass,
 const atl::String& inName,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inConnector	Optional<String>	NIL	Connector
	inDestinationClass	MultiCamDestinationClass::Type		Class where the value should be set (board or channel)
	inName	const String&		Parameter name
	inValue	int		Parameter value

MultiCam_SetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type real into euresys device.

Syntax

```
void avl::MultiCam_SetRealParameter
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inConnector,
 avl::MultiCamDestinationClass::Type inDestinationClass,
 const atl::String& inName,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inConnector	Optional<String>	NIL	Connector
	inDestinationClass	MultiCamDestinationClass::Type		Class where the value should be set (board or channel)

MultiCam_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type String into euresys device.

Syntax

```
void avl::MultiCam_SetStringParameter
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inConnector,
 avl::MultiCamDestinationClass::Type inDestinationClass,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	MultiCam_State&		Object used to maintain state of the function.
	inDeviceID	Optional<String>	NIL	Board name, board identifier or serial number
	inConnector	Optional<String>	NIL	Connector
	inDestinationClass	MultiCamDestinationClass::Type		Class where the value should be set (board or channel)
	inName	const String&		Parameter name
	inValue	const String&		Parameter value

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

MultiCam_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition by frame grabber.

Syntax

```
void avl::MultiCam_StartAcquisition
(
 MultiCam_State& ioState,
 atl::Optional<atl::String> inDeviceID,
 atl::Optional<atl::String> inTopology,
 atl::Optional<atl::String> inCameraTapConfiguration,
 const atl::String& inConnector,
 avl::MultiCamAcquisitionMode::Type inAcquisitionMode,
 atl::Optional<const atl::File&> inCameraFile,
 atl::Optional<int> inPageLengthLn,
 avl::MultiCamColorFormat::Type inColorFormat,
 atl::Optional<int> inGain,
 atl::Optional<int> inSurfaceCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	MultiCam_State&			Object used to maintain state of the function.
	inDeviceID	Optional<String>		NIL	Board name, board identifier or serial number
	inTopology	Optional<String>		NIL	Board topology
	inCameraTapConfiguration	Optional<String>		NIL	Tap configuration of camera
	inConnector	const String&			Indication of connector used by channel
	inAcquisitionMode	MultiCamAcquisitionMode::Type			Acquisition Mode
	inCameraFile	Optional<const File&>		NIL	Camera configuration file
	inPageLengthLn	Optional<int>	1 – 65535	NIL	Page Length
	inColorFormat	MultiCamColorFormat::Type			Color format
	inGain	Optional<int>		NIL	Linear control of gain for all digitizing units
	inSurfaceCount	Optional<int>	1 – 4096	3	Number of allocated surfaces

mvGenTLAcquire_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::mvGenTLAcquire_GenerateSoftwareTrigger
(
 mvGenTLAcquireState& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	mvGenTLAcquireState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device name or serial number of device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

mvGenTLAcquire_GetDigitalIOState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns the state of digital inputs or outputs from matrix vision cameras.

Syntax

```
void avl::mvGenTLAcquire_GetDigitalIOState
(
 mvGenTLAcquireState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inIOIndex,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
⇆	ioState	mvGenTLAcquireState&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device name or serial number of device
→	inIOIndex	int		Index of input or output line
←	outValue	bool&		State of IO line

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install mvGenTL Acquire SDK software with camera dedicated drivers.

mvGenTL Acquire SDK software can be downloaded from the following website: www.matrix-vision.com. For Aurora Vision Studio 32-bit, mvGenTL Acquire x86 version is needed. For Aurora Vision Studio 64-bit, mvGenTL Acquire x86_x64 version of SDK is required.

Recommended mvGenTL Acquire SDK version for usage with Aurora Vision Studio is **2.49.0**.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- **serial number** - it should be specified on the device casing(e.g. *GX001559*),
- **product name** - it finds camera by name (might be the same for many cameras). The product name is a bit more specific than the family name, but less specific than the serial number(e.g. *mvBlueCOUGAR-X100wG*),
- **product number** - it finds camera by family name(e.g. *mvBlueCOUGAR*).

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

mvGenTLAcquire_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame from MATRIX VISION cameras using mvGenTLAcquire SDK.

Syntax

```
bool avl::mvGenTLAcquire_GrabImage
(
 mvGenTLAcquireState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<avl::MVGenTLPixelFormat::Type> inPixelFormat,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<float> inFrameRate,
 atl::Optional<const avl::Box&> inAoi,
 avl::MvIMPACTTriggerActivation::Type inTriggerMode,
 avl::MvIMPACTTriggerSource::Type inTriggerSource,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	mvGenTLAcquireState&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device name or serial number of device
	inPixelFormat	Optional<MVGenTLPixelFormat::Type>		NIL	Pixel format of output image
	inExposureTime	Optional<int>	1 – +∞	NIL	Exposure time value
	inGain	Optional<float>		NIL	Gain value
	inFrameRate	Optional<float>	1.0 – ∞	NIL	Frame rate in FPS
	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
	inTriggerMode	MvIMPACTTriggerActivation::Type			Trigger mode
	inTriggerSource	MvIMPACTTriggerSource::Type			Source of trigger
	outImage	Image&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install mvGenTL Acquire SDK software with camera dedicated drivers.

mvGenTL Acquire SDK software can be downloaded from the following website: www.matrix-vision.com. For Aurora Vision Studio 32-bit, mvGenTL Acquire x86 version is needed. For Aurora Vision Studio 64-bit, mvGenTL Acquire x86_x64 version of SDK is required.

Recommended mvGenTL Acquire SDK version for usage with Aurora Vision Studio is **2.49.0**.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- **serial number** – it should be specified on the device casing(e.g. *GX001559*),
- **product name** – it finds camera by name (might be the same for many cameras). The product name is a bit more specific than the family name, but less specific than the serial number(e.g. *mvBlueCOUGAR-X100wG*),
- **product number** – it finds camera by family name(e.g. *mvBlueCOUGAR*).

Camera parameters

Most of the parameters exposed by camera filters are optional, setting them to *Auto* leaves related parameter for automatic configuration by the camera driver.

To change other and more advanced camera parameters, use the wxPropView available with mvGenTL Acquire SDK. Refer to SDK documentation for information about parameters and how to save them into memory channels.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

mvGenTLAcquire_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame from MATRIX VISION cameras using mvGenTLAcquire SDK.

Syntax

```
bool avl::mvGenTLAcquire_GrabImage_WithTimeout
(
 mvGenTLAcquireState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 atl::Optional<avl::MVGenTLPixelFormat::Type> inPixelFormat,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<float> inFrameRate,
 atl::Optional<const avl::Box&> inAoi,
 avl::MvIMPACTTriggerActivation::Type inTriggerMode,
 avl::MvIMPACTTriggerSource::Type inTriggerSource,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	mvGenTLAcquireState&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device name or serial number of device
→	inTimeout	int	10 - ∞	100	Maximum time to wait for frame in milliseconds
→	inPixelFormat	Optional<MVGenTLPixelFormat::Type>		NIL	Pixel format of output image
→	inExposureTime	Optional<int>	1 - + ∞	NIL	Exposure time value
→	inGain	Optional<float>		NIL	Gain value
→	inFrameRate	Optional<float>	1.0 - ∞	NIL	Frame rate in FPS

→	inTriggerMode	MvIMPACTTriggerActivation::Type			Trigger mode
→	inTriggerSource	MvIMPACTTriggerSource::Type			Source of trigger
←	outImage	Conditional<Image>&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install mvGenTL Acquire SDK software with camera dedicated drivers.

mvGenTL Acquire SDK software can be downloaded from the following website: www.matrix-vision.com. For Aurora Vision Studio 32-bit, mvGenTL Acquire x86 version is needed. For Aurora Vision Studio 64-bit, mvGenTL Acquire x86_x64 version of SDK is required.

Recommended mvGenTL Acquire SDK version for usage with Aurora Vision Studio is **2.49.0**.

Camera identification

When there is only one camera connected to the computer, field **inDeviceID** can be set to *Auto*. In such case, first available camera will be found and connected.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** can be set to:

- **serial number** - it should be specified on the device casing(e.g. *GX001559*),
- **product name** - it finds camera by name (might be the same for many cameras). The product name is a bit more specific than the family name, but less specific than the serial number(e.g. *mvBlueCOUGAR-X100wG*),
- **product number** - it finds camera by family name(e.g. *mvBlueCOUGAR*).

Camera parameters

Most of the parameters exposed by camera filters are optional, setting them to *Auto* leaves related parameter for automatic configuration by the camera driver.

To change other and more advanced camera parameters, use the wxPropView available with mvGenTL Acquire SDK. Refer to SDK documentation for information about parameters and how to save them into memory channels.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- mvGenTLAcquire_SetDigitalOutput - Sets matrix vision camera digital outputs.

mvGenTLAcquire_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets matrix vision camera digital outputs.

Syntax

```
void avl::mvGenTLAcquire_SetDigitalOutput
(
 mvGenTLAcquireState& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inOutput,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	mvGenTLAcquireState&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device name or serial number of device
	inOutput	int		Index of output line
	inValue	bool		Logic value of digital output

Neousys_GetDigitalInput_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets values of all digital input channels at once on a Neousys computer.

Syntax

```
void avl::Neousys_GetDigitalInput_Multiple
(
 Neousys_State& ioState,
 bool& outValue0,
 bool& outValue1,
 bool& outValue2,
 bool& outValue3,
 bool& outValue4,
 bool& outValue5,
 bool& outValue6,
 bool& outValue7,
 bool& outValue8,
 bool& outValue9,
 bool& outValue10,
 bool& outValue11,
 bool& outValue12,
 bool& outValue13,
 bool& outValue14,
 bool& outValue15
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.
	outValue0	bool&		Value to get from input channel 0
	outValue1	bool&		Value to get from input channel 1
	outValue2	bool&		Value to get from input channel 2
	outValue3	bool&		Value to get from input channel 3
	outValue4	bool&		Value to get from input channel 4
	outValue5	bool&		Value to get from input channel 5
	outValue6	bool&		Value to get from input channel 6
	outValue7	bool&		Value to get from input channel 7
	outValue8	bool&		Value to get from input channel 8
	outValue9	bool&		Value to get from input channel 9

Neousys_GetDigitalInput_MultipleAsArray

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets values of all digital input channels at once on a Neousys computer passed in an array form.

Syntax

```
void avl::Neousys_GetDigitalInput_MultipleAsArray
(
 Neousys_State& ioState,
 atl::Array<bool>& outValues
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.
	outValues	Array<bool>&		Values to get from input channels (16 items)

Remarks

Neousys_GetDigitalInput_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets value of single digital input channel on a Neousys computer.

Syntax

```
void avl::Neousys_GetDigitalInput_Single
(
 Neousys_State& ioState,
 int inChannel,
 bool& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Neousys_State&			Object used to maintain state of the function.
	inChannel	int	0 – 15		Desired input channel identifier
	outValue	bool&			Value to get from desired input channel

Remarks

See Also

- Neousys_SetDigitalOutput_Single – Sets value to single digital output channel on a Neousys computer.

Neousys_ResetWatchdogTimer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets watchdog timer countdown on a Neousys computer.

Syntax

```
void avl::Neousys_ResetWatchdogTimer
(
 Neousys_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.

Description

Sets watchdog timer back to the reference value in order to prevent it from reaching 0 and restarting the device.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it may be required to install WDT_DIO drivers and SDK.

WDT_DIO can be downloaded from the following website: https://www.neousys-tech.com/en/support-service/download-resources.

Add DLL path to system environment variable may be required.

Recommended WDT_DIO version for Aurora Vision Studio usage is **2.3.1**.

Availability

Before you use this filter make sure that your Neousys device has a watchdog unit.

Initialization

When the watchdog unit is initialized it's default countdown value is set to 255 seconds.

Operation

When the program exits watchdog unit is always stopped and its parameters are set to default, so make sure to keep the program running when it encounters an error that should trigger the watchdog unit.

Compatibility

Neousys Watchdog Timer and Digital I/O support is not provided when using 32-bit Aurora Vision on a 64-bit operating system. Please use 64-bit Aurora Vision in such a case.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	Could not reset watchdog timer.

See Also

- Neousys_SetWatchdogTimer – Sets watchdog timer properties on a Neousys computer.
- Neousys_StartWatchdogTimer – Starts watchdog timer countdown on a Neousys computer.
- Neousys_StopWatchdogTimer – Stops watchdog timer countdown on a Neousys computer.

Neousys_SetDigitalOutput_Multiple

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets values to all digital output channels at once on a Neousys computer.

Syntax

```
void avl::Neousys_SetDigitalOutput_Multiple
(
 Neousys_State& ioState,
 bool inValue0,
 bool inValue1 = false,
 bool inValue2 = false,
 bool inValue3 = false,
 bool inValue4 = false,
 bool inValue5 = false,
 bool inValue6 = false,
 bool inValue7 = false,
 bool inValue8 = false,
 bool inValue9 = false,
 bool inValue10 = false,
 bool inValue11 = false,
 bool inValue12 = false,
 bool inValue13 = false,
 bool inValue14 = false,
 bool inValue15 = false
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.
	inValue0	bool		Value to set to output channel 0
	inValue1	bool	false	Value to set to output channel 1
	inValue2	bool	false	Value to set to output channel 2
	inValue3	bool	false	Value to set to output channel 3
	inValue4	bool	false	Value to set to output channel 4
	inValue5	bool	false	Value to set to output channel 5
	inValue6	bool	false	Value to set to output channel 6
	inValue7	bool	false	Value to set to output channel 7
	inValue8	bool	false	Value to set to output channel 8
	inValue9	bool	false	Value to set to output channel 9
	inValue10	bool	false	Value to set to output channel 10
	inValue11	bool	false	Value to set to output channel 11
	inValue12	bool	false	Value to set to output channel 12
	inValue13	bool	false	Value to set to output channel 13

Availability

Before you use this filter make sure that your Neousys device has a watchdog unit.

Initialization

When the watchdog unit is initialized it's default countdown value is set to 255 seconds.

Operation

When the program exits watchdog unit is always stopped and its parameters are set to default, so make sure to keep the program running when it encounters an error that should trigger the watchdog unit.

Limits

Depending on the device there might be limits on the **inTicks** value depending on the **inUnit** value. Please refer to your Neousys device manual when in doubt.

Compatibility

Neousys Watchdog Timer and Digital I/O support is not provided when using 32-bit Aurora Vision on a 64-bit operating system. Please use 64-bit Aurora Vision in such a case.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	Could not set watchdog timer.

See Also

- Neousys_StartWatchdogTimer – Starts watchdog timer countdown on a Neousys computer.
- Neousys_ResetWatchdogTimer – Resets watchdog timer countdown on a Neousys computer.
- Neousys_StopWatchdogTimer – Stops watchdog timer countdown on a Neousys computer.

Neousys_StartWatchdogTimer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts watchdog timer countdown on a Neousys computer.

Syntax

```
void avl::Neousys_StartWatchdogTimer
(
 Neousys_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.

Remarks

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it may be required to install WDT_DIO drivers and SDK.

WDT_DIO can be downloaded from the following website: https://www.neousys-tech.com/en/support-service/download-resources.

Add DLL path to system environment variable may be required.

Recommended WDT_DIO version for Aurora Vision Studio usage is **2.3.1**.

Availability

Before you use this filter make sure that your Neousys device has a watchdog unit.

Initialization

When the watchdog unit is initialized it's default countdown value is set to 255 seconds.

Operation

When the program exits watchdog unit is always stopped and its parameters are set to default, so make sure to keep the program running when it encounters an error that should trigger the watchdog unit.

Compatibility

Neousys Watchdog Timer and Digital I/O support is not provided when using 32-bit Aurora Vision on a 64-bit operating system. Please use 64-bit Aurora Vision in such a case.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
IoError	Could not start watchdog timer.

See Also

- Neousys_SetWatchdogTimer – Sets watchdog timer properties on a Neousys computer.
- Neousys_ResetWatchdogTimer – Resets watchdog timer countdown on a Neousys computer.
- Neousys_StopWatchdogTimer – Stops watchdog timer countdown on a Neousys computer.

Neousys_StopWatchdogTimer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops watchdog timer countdown on a Neousys computer.

Syntax

```
void avl::Neousys_StopWatchdogTimer
(
 Neousys_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Neousys_State&		Object used to maintain state of the function.

Remarks

Nodka_GetGeneralParam

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets general parameters of the controller.

Syntax

```
void avl::Nodka_GetGeneralParam
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 avl::NodkaGeneralParameter::Type inParamId,
 int inParamLen,
 int inTimeout,
 int& outParamValue
)
```

Parameters

	Name	Type	Range	Default	Description
⇆	ioState	Nodka_State&			Object used to maintain state of the function.
→	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
→	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
→	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
→	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
→	inParamId	NodkaGeneralParameter::Type			ID of the parameter.
→	inParamLen	int	0 – 255	1	Length of the parameter (refer to NKIO_API user manual).
→	inTimeout	int	0 – ∞	100	Timeout for the callback function.
←	outParamValue	int&			Value of the parameter.

Remarks

This filter can be used to get the value of general parameters of the controller (refer to NKIO_API user manual for more information).

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** – a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. A new configuration file must be provided for each distinct value of **inServerPort**. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** – a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_SetGeneralParam – Sets general parameters of the controller.

Nodka_GetPwmParams

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameters of the light controller.

Syntax

```
void avl::Nodka_GetPwmParams
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 avl::NodkaLightControlChannel::Type inChIdx,
 int inTimeout,
 avl::NodkaPwmMode::Type& outPwmMode,
 int& outPwmValue,
 int& outPwmHoldingTime,
 int& outPwmOnOff
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Nodka_State&			Object used to maintain state of the function.
→	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
→	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
→	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
→	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
→	inChIdx	NodkaLightControlChannel::Type			Light controller channel ID.
→	inTimeout	int	0 – ∞	100	Timeout for the callback function.
←	outPwmMode	NodkaPwmMode::Type&			Trigger mode of the light controller.
←	outPwmValue	int&			Brightness level of the light controller.
←	outPwmHoldingTime	int&			Duration of the 'on' state of the light controller (see also: Nodka_SetHoldingTimeUnit).
←	outPwmOnOff	int&			Parameter to turn the light on or off.

Remarks

This filter can be used to get the parameters of the specified light control channel.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** – a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. A new configuration file must be provided for each distinct value of **inServerPort**. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** – a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_SetPwmParams – Sets parameters of the light controller.

Nodka_GetVersionInfo

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets information about the hardware and the firmware of the device.

Syntax

```
void avl::Nodka_GetVersionInfo
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 int inTimeout,
 int& outHardwareMajorVer,
 int& outHardwareMinorVer,
 int& outHardwareRevVer,
 int& outFirmwareMajorVer,
 int& outFirmwareMinorVer,
 int& outFirmwareRevVer
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
	inTimeout	int	0 – ∞	100	Timeout for the callback function.
	outHardwareMajorVer	int&			Device hardware major version.
	outHardwareMinorVer	int&			Device hardware minor version.
	outHardwareRevVer	int&			Device hardware revision version.
	outFirmwareMajorVer	int&			Device firmware major version.
	outFirmwareMinorVer	int&			Device firmware minor version.
	outFirmwareRevVer	int&			Device firmware revision version.

Remarks

This filter can be used to get the information about the hardware and the firmware version of the device.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

Nodka_Initialize

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes Nodka NKIO_API SDK.

Syntax

```
void avl::Nodka_Initialize
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 const atl::File& inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	44100	Port of NodkaServer service.
	inDeviceConfigPath	const File&			Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).

Remarks

This filter can be used to explicitly initialize device parameters before using other Nodka filters.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Nodka_ReadInputLevel_Channel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a single input channel.

Syntax

```
void avl::Nodka_ReadInputLevel_Channel
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inPortIndex,
 int inChannelIndex,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inPortIndex	int	0 – 1		Input port number.
	inChannelIndex	int	0 – 7		Input port channel.
	outLevel	bool&			Input channel level.

Remarks

This filter allows to get the input level information of a single input channel of the device.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** - a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** - a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** - a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_ReadInputLevel_Port - Reads an entire input port.

Nodka_ReadInputLevel_Port

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads an entire input port.

Syntax

```
void avl::Nodka_ReadInputLevel_Port
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inPortIndex,
 atl::Array<bool>& outLevels
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Nodka_State&			Object used to maintain state of the function.
→	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
→	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
→	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
→	inPortIndex	int	0 – 1		Input port number.
←	outLevels	Array<bool>&			Input port levels.

Remarks

This filter allows to get the input level information of a specific input port of the device (8 input channels).

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** – a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. A new configuration file must be provided for each distinct value of **inServerPort**. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** – a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_ReadInputLevel_Channel – Reads a single input channel.

Nodka_ReadOutputLevel_Channel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a single output channel.

Syntax

```
void avl::Nodka_ReadOutputLevel_Channel
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inPortIndex,
 int inChannelIndex,
 bool& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inPortIndex	int	0 – 1		Output port number.
	inChannelIndex	int	0 – 7		Output port channel.
	outLevel	bool&			Output channel level.

Remarks

This filter allows to get the output level information of a single output channel of the device.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Nodka_SetGeneralParam

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets general parameters of the controller.

Syntax

```
void avl::Nodka_SetGeneralParam
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 avl::NodkaGeneralParameter::Type inParamId,
 int inParamLen,
 int inParamValue,
 int inTimeout
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
	inParamId	NodkaGeneralParameter::Type			ID of the parameter.
	inParamLen	int	0 – 255	1	Length of the parameter (refer to NKIO_API user manual).
	inParamValue	int	0 – ∞		Value of the parameter (refer to NKIO_API user manual).
	inTimeout	int	0 – ∞	100	Timeout for the callback function.

Remarks

This filter can be used to set the value of general parameters of the controller (refer to NKIO_API user manual for more information).

Nodka_SetHoldingTimeUnit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a holding time unit for a specific channel of the light controller.

Syntax

```
void avl::Nodka_SetHoldingTimeUnit
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 avl::NodkaLightControlChannel::Type inChannel,
 avl::NodkaHoldingTime::Type inHoldingTime,
 int inTimeout
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
	inChannel	NodkaLightControlChannel::Type			Light controller channel ID.
	inHoldingTime	NodkaHoldingTime::Type			Holding time unit.
	inTimeout	int	0 – ∞	100	Timeout for the callback function.

Remarks

This filter can be used to set the value of the holding time unit for a specific channel of the light controller (refer to NKIO_API user manual for more information).

Nodka_SetPwmParamsNoRetentive

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameters of the light controller. The set parameters will be lost after reboot.

Syntax

```
void avl::Nodka_SetPwmParamsNoRetentive
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inDevId,
 avl::NodkaLightControlChannel::Type inChIdx,
 avl::NodkaPwmMode::Type inPwmMode,
 int inPwmValue,
 int inPwmHoldingTime,
 int inPwmOnOff,
 int inTimeout
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inDevId	int	0 – 255		ID of the device (0x01 for the light controller).
	inChIdx	NodkaLightControlChannel::Type			Light controller channel ID.
	inPwmMode	NodkaPwmMode::Type			Trigger mode of the light controller.
	inPwmValue	int	0 – 100		Brightness level of the light controller.
	inPwmHoldingTime	int	0 – 255		Duration of the 'on' state of the light controller (see also: Nodka_SetHoldingTimeUnit).
	inPwmOnOff	int	0 – 1		Parameter to turn the light on or off.
	inTimeout	int	0 – ∞	100	Timeout for the callback function.

Remarks

This filter can be used to set the parameters of the specified light control channel without saving the parameters. Please note that the set parameters will be lost after reboot when using this filter.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** – a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. A new configuration file must be provided for each distinct value of **inServerPort**. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** – a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_SetPwmParams – Sets parameters of the light controller.
- Nodka_GetPwmParams – Gets parameters of the light controller.

Nodka_WriteOutputLevel_Channel

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes a single output channel.

Syntax

```
void avl::Nodka_WriteOutputLevel_Channel
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inPortIndex,
 int inChannelIndex,
 bool inLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inPortIndex	int	0 – 1		Output port number.
	inChannelIndex	int	0 – 7		Output port channel.
	inLevel	bool			Output channel level.

Remarks

This filter allows to set the output level for a single output channel of the device.

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. The filters in Aurora Vision Studio work as a client which communicates with the server and they don't use the SDK directly. Only localhost connections are allowed.

It is mandatory to run the Nodka_Server.exe program **with administrative privileges** and keep it running during the execution of this and other Nodka filters.

For the correct operation of the program, it is required to copy the WinRing0.sys and WinRing0x64.sys files from the SDK directory to the directory where the Nodka_Server.exe file is located. These files are placed in C:\NODKA\NKDIO_SDK\Lib\x86 and C:\NODKA\NKDIO_SDK\Lib\x64 directories by default. Choose those that match your operating system version. Adding the directory to the PATH system variable will likely not work.

To run the program, open the Command Prompt as administrator, navigate to the directory where Nodka_Server.exe file is situated and then run the command `Nodka_Server.exe --port PORT` where 'PORT' is a TCP port on which the server will be listening (an integer value from the range 1-65535). Aurora Vision uses port 44100 by default so it is recommended to choose this one.

The Nodka_Server.exe program can be found in Aurora Vision installation path.

Some ports may operate in reverse logic. For details, refer to the electronic input and output diagram documentation of the device.

Device identification

inServerPort field is used to select a TCP port on which the Nodka_Server.exe is listening. Setting this parameter to 'Auto' will select port 44100 which is the default value. ServerPort can be set to:

- **TCP port** – a TCP port on which the Nodka_Server.exe is listening.

inDeviceConfigPath field is used to select a path to the configuration file for a specific Nodka device model. This field cannot be empty for the first Nodka filter used. For each of the following filters with the same value of **inServerPort**, the value of this field can be set to 'Auto' which would result in using the previously specified configuration file. A new configuration file must be provided for each distinct value of **inServerPort**. The Nodka NKDIO SDK installer puts the configuration files in C:\NODKA\NKDIO_SDK\ConfigFile directory by default. The SDK does not check if the specified configuration file is correct, so any errors in the configuration file may be ignored by the SDK. DeviceConfigPath can be set to:

- **File path** – a path to the configuration file for a specific Nodka device model.

inDeviceLightControllerPort field is used to select the COM port of the on-board light controller. Please note that not all Nodka devices have an on-board light controller. For more information refer to the documentation of the specific model. This field is optional and for devices without the light controller should be set to 'Auto'. DeviceLightControllerPort can be set to:

- **COM port** – a COM port of the on-board light controller.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Nodka_WriteOutputLevel_Port – Writes an entire output port.

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes an entire output port.

Syntax

```
void avl::Nodka_WriteOutputLevel_Port
(
 Nodka_State& ioState,
 atl::Optional<int> inServerPort,
 atl::Optional<const atl::File&> inDeviceConfigPath,
 atl::Optional<int> inDeviceLightControllerPort,
 int inPortIndex,
 const atl::Array<bool>& inLevels
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Nodka_State&			Object used to maintain state of the function.
	inServerPort	Optional<int>	1 – 65535	NIL	Port of NodkaServer service.
	inDeviceConfigPath	Optional<const File&>		NIL	Path to nkio_config.ini file with I/O configuration.
	inDeviceLightControllerPort	Optional<int>	1 – ∞	NIL	COM port used by the light controller (if supported by the device).
	inPortIndex	int	0 – 1		Output port number.
	inLevels	const Array<bool>&			Output port levels.

Remarks

This filter allows to set the output level for a specific output port of the device (8 output channels).

I/O device driver software

This filter is intended to cooperate with a Nodka device using its vendor SDK and Nodka_Server.exe program. To be able to connect to the device, it is required to install Nodka NKDIO SDK.

Add DLL path to system environment variable may be required.

Recommended Nodka NKDIO SDK version for Aurora Vision Studio usage is **v4.1.9**. The implementation of all SDK functionality is done in Nodka_Server.exe program. 185. Kinect

Table of content:

- OpenNI_GrabImage
- OpenNI_SkeletonTracing

Also in AVL Lite

OpenNI_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Kinect.

Syntax

```
bool avl::OpenNI_GrabImage
(
 OpenNI_GrabImageState& ioState,
 avl::Image& outImage,
 avl::Image& outDepthImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	OpenNI_GrabImageState&		Object used to maintain state of the function.
	outImage	Image&		Captured frame
	outDepthImage	Image&		

Description

To be able to grab images using Kinect you need to install:

- Kinect SDK 1.8
- OpenNI 2.2
- NITE 2.2

Please contact our support to get OpenNI / NITE installers.

Installed software must match the Aurora Vision Studio platform (x86 or x64).

After installing these files you have to manually copy all the files and directories from *OpenNI2\Redist* directory and all the dll files from the *PrimeSense\NiTE2\Redist* directory to your Aurora Vision Studio main directory.

Additionally, if you save the project in which you are using the skeleton tracing feature, you should copy the *PrimeSense\NiTE2\Redist\NiTE2* directory also to the project directory.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- OpenNI_SkeletonTracing – Captures a skeleton using Kinect.

OpenNI_SkeletonTracing

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a skeleton using Kinect.

Syntax

```
bool avl::OpenNI_SkeletonTracing
(
 OpenNI_SkeletonTracingState& ioState,
 int& outNumberOfPersons,
 atl::Array<atl::Array<avl::Point2D>>& outSkeletons,
 avl::Region& outPlayerRegion
)
```

Parameters

	Name	Type	Default	Description
	ioState	OpenNI_SkeletonTracingState&		Object used to maintain state of the function.
	outNumberOfPersons	int&		
	outSkeletons	Array<Array<Point2D>>&		
	outPlayerRegion	Region&		

Description

To be able to grab images using Kinect you need to install:

OptoEngineeringHRAS_COE71_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using COE-71 Opto Engineering device.

Syntax

```
bool avl::OptoEngineeringHRAS_COE71_GrabImage
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::OptoEngineeringBitDepth::Type inBitDepth,
 atl::Optional<avl::OptoEngineering_COE71_StrobePolarity::Type> inStrobePolarity,
 avl::OptoEngineering_COE71_TriggerMode::Type inTriggerMode,
 atl::Optional<float> inDigitalGain,
 atl::Optional<int> inDigitalOffset,
 atl::Optional<int> inExposureTime,
 avl::OptoEngineeringExposureUnit::Type inExposureUnit,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	OptoEngineering_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inBitDepth	OptoEngineeringBitDepth::Type			Number of pixel bits
→	inStrobePolarity	Optional<OptoEngineering_COE71_StrobePolarity::Type>		NIL	Polarity of strobe output signal
→	inTriggerMode	OptoEngineering_COE71_TriggerMode::Type			Device triggering mode
→	inDigitalGain	Optional<float>	0.0 – 16.0	NIL	Gain of source image in device raw unit
→	inDigitalOffset	Optional<int>	-32767 – 32767	NIL	Offset of source image in device raw unit
→	inExposureTime	Optional<int>	1 – 65535	NIL	Camera frame exposition time
→	inExposureUnit	OptoEngineeringExposureUnit::Type			Camera frame exposition time unit
←	outImage	Image&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS software with camera dedicated drivers.

eBUS SDK can be downloaded from the following website: https://supportcenter.pleora.com/s/topic/0TO340000004X6dGAE/ebus-sdk?tabset-0c866=2&tabset-25adb=81d66 (registration may be required).

Recommended eBUS SDK version for Aurora Vision Studio usage is **5.1.10.4642**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Device unique id number** - should be specified on device casing.

Camera parameters

To change other and more advanced internal camera parameters use configuration tool "Camera Control Application" available from the following website: https://www.opto-e.com/products/coe-area-scan#Downloads (registration may be required).

Other device settings can be changed also with eBUs Player available from the following website: https://www.pleora.com/products/ebus-sdk/ (registration may be required).

Supported devices

This filter support only COE HR AS 50, 71 and 29 series with USB interface. COE-71 devices have dedicated support.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

OptoEngineeringHRAS_COE71_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using COE-71 Opto Engineering device.

Syntax

```
bool avl::OptoEngineeringHRAS_COE71_GrabImage_WithTimeout
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 int inInputQueueSize,
 avl::OptoEngineeringBitDepth::Type inBitDepth,
 atl::Optional<avl::OptoEngineering_COE71_StrobePolarity::Type> inStrobePolarity,
 avl::OptoEngineering_COE71_TriggerMode::Type inTriggerMode,
 atl::Optional<float> inDigitalGain,
 atl::Optional<int> inDigitalOffset,
 atl::Optional<int> inExposureTime,
 avl::OptoEngineeringExposureUnit::Type inExposureUnit,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	OptoEngineering_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inTimeout	int	100 – ∞	100	Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inBitDepth	OptoEngineeringBitDepth::Type			Number of pixel bits
→	inStrobePolarity	Optional<OptoEngineering_COE71_StrobePolarity::Type>		NIL	Polarity of strobe output signal
→	inTriggerMode	OptoEngineering_COE71_TriggerMode::Type			Device triggering mode
→	inDigitalGain	Optional<float>	0.0 – 16.0	NIL	Gain of source image in device raw unit
→	inDigitalOffset	Optional<int>	-32767 – 32767	NIL	Offset of source image in device raw unit
→	inExposureTime	Optional<int>	1 – 65535	NIL	Camera frame exposition time
→	inExposureUnit	OptoEngineeringExposureUnit::Type			Camera frame exposition time unit
←	outImage	Conditional<Image>&			Captured frame

OptoEngineeringHRAS_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::OptoEngineeringHRAS_GenerateSoftwareTrigger
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	OptoEngineering_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inTime	int	1 – 65535	100	Duration of trigger in milliseconds

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GetBooleanParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type Bool from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetBooleanParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GetEnumParameterAsInteger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type Enum from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetEnumParameterAsInteger
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GetEnumParameterAsString

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type Enum from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetEnumParameterAsString
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	OptoEngineering_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying number
→	inName	const String&		Parameter name
←	outValue	String&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GetFloatParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type Float from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetFloatParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	OptoEngineering_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying number
→	inName	const String&		Parameter name
←	outValue	double&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type Integer from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetIntegerParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

OptoEngineeringHRAS_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets Genicam parameter of type String from internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_GetStringParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	String&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using Opto Engineering device.

Syntax

```
bool avl::OptoEngineeringHRAS_GrabImage
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	OptoEngineering_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
←	outImage	Image&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS software with camera dedicated drivers.

eBUS SDK can be downloaded from the following website: https://supportcenter.pleora.com/s/topic/0TO340000004X6dGAE/ebus-sdk?tabset-0c866=2&tabset-25adb=81d66 (registration may be required).

Recommended eBUS SDK version for Aurora Vision Studio usage is **5.1.10.4642**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Device unique id number** – should be specified on device casing.

Camera parameters

To change other and more advanced internal camera parameters use configuration tool "Camera Control Application" available from the following website: https://www.opto-e.com/products/coe-area-scan#Downloads (registration may be required).

Other device settings can be changed also with eBUs Player available from the following website: https://www.pleora.com/products/ebus-sdk/ (registration may be required).

Supported devices

This filter support only COE HR AS 50, 71 and 29 series with USB interface. COE-71 devices have dedicated support.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- OptoEngineeringHRAS_GrabImage_WithTimeout – Captures with timeout an image using Opto Engineering device.
- OptoEngineeringHRAS_StartAcquisition – Initializes and starts image acquisition in a camera.
- OptoEngineeringHRAS_COE71_GrabImage – Captures an image using COE-71 Opto Engineering device.

OptoEngineeringHRAS_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures with timeout an image using Opto Engineering device.

Syntax

```
bool avl::OptoEngineeringHRAS_GrabImage_WithTimeout
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 int inInputQueueSize,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	OptoEngineering_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inTimeout	int	100 – ∞	100	Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
←	outImage	Conditional<Image>&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS software with camera dedicated drivers.

eBUS SDK can be downloaded from the following website: https://supportcenter.pleora.com/s/topic/0TO340000004X6dGAE/ebus-sdk?tabset-0c866=2&tabset-25adb=81d66 (registration may be required).

Recommended eBUS SDK version for Aurora Vision Studio usage is **5.1.10.4642**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

OptoEngineeringHRAS_SendSerialRawCommand

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets serial port internal protocol frame to device.

Syntax

```
void avl::OptoEngineeringHRAS_SendSerialRawCommand
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const avl::OptoEngineeringSerialFrame& inData,
 atl::Conditional<avl::OptoEngineeringSerialFrame>& outResponse
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inData	const OptoEngineeringSerialFrame&		Input frame command
	outResponse	Conditional<OptoEngineeringSerialFrame>&		Output frame, set only for read mode

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS software with camera dedicated drivers.

eBUS SDK can be downloaded from the following website: https://supportcenter.pleora.com/s/topic/0TO340000004X6dGAE/ebus-sdk?tabset-0c866=2&tabset-25adb=81d66 (registration may be required).

Recommended eBUS SDK version for Aurora Vision Studio usage is **5.1.10.4642**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Device unique id number** - should be specified on device casing.

Camera parameters

To change other and more advanced internal camera parameters use configuration tool "Camera Control Application" available from the following website: https://www.opto-e.com/products/coe-area-scan#Downloads (registration may be required).

Other device settings can be changed also with eBUs Player available from the following website: https://www.pleora.com/products/ebus-sdk/ (registration may be required).

Supported devices

This filter support only COE HR AS 50, 71 and 29 series with USB interface. COE-71 devices have dedicated support.

Application example

This filter provide implementation of internal protocol based on serial port.

Parameters must be formatted as hexadecimal number in string. Data field can be set empty - it will be autofill as zero.

Parameters list for each device can be find here: https://www.opto-e.com/products/coe-area-scan#Downloads (registration may be required).

For example, to read camera temperature use target: 04, index: 07, data: 0000. Checksum is automatic calculated.

This filter can fail you retry send command every loop iteration.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetBooleanParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type Bool to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetBooleanParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	bool		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetDigitalGain

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital gain.

Syntax

```
void avl::OptoEngineeringHRAS_SetDigitalGain
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 float inGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	OptoEngineering_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inGain	float	0.0 – 16.0	1.0f	Gain of source image in device raw unit

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetDigitalOffset

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital offset.

Syntax

```
void avl::OptoEngineeringHRAS_SetDigitalOffset
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inOffset
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	OptoEngineering_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inOffset	int	-32767 – 32767	0	Offset of source image in device raw unit

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetEnumParameterAsInteger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type Enum to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetEnumParameterAsInteger
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	int64		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

OptoEngineeringHRAS_SetEnumParameterAsString

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type Enum to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetEnumParameterAsString
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	const String&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetFloatParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type Float to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetFloatParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	double		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

OptoEngineeringHRAS_SetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type Integer to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetIntegerParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	int64		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Genicam parameter of type String to internal frame grabber.

Syntax

```
void avl::OptoEngineeringHRAS_SetStringParameter
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	const String&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

OptoEngineeringHRAS_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::OptoEngineeringHRAS_StartAcquisition
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	OptoEngineering_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install eBUS software with camera dedicated drivers.

eBUS SDK can be downloaded from the following website: https://supportcenter.pleora.com/s/topic/0TO340000004X6dGAE/ebus-sdk?tabset-0c866=2&tabset-25adb=81d66 (registration may be required).

Recommended eBUS SDK version for Aurora Vision Studio usage is **5.1.10.4642**.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Device unique id number** - should be specified on device casing.

Camera parameters

To change other and more advanced internal camera parameters use configuration tool "Camera Control Application" available from the following website: https://www.opto-e.com/products/coe-area-scan#Downloads (registration may be required).

Other device settings can be changed also with eBUs Player available from the following website: https://www.pleora.com/products/ebus-sdk/ (registration may be required).

Supported devices

This filter support only COE HR AS 50, 71 and 29 series with USB interface. COE-71 devices have dedicated support.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

OptoEngineeringHRAS_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::OptoEngineeringHRAS_StopAcquisition
(
 OptoEngineering_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	OptoEngineering_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Photoneo_DecodeColorFrame

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Converts raw color frame to RGB image.

Syntax

```
void avl::Photoneo_DecodeColorFrame
(
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
→	inImage	const Image&		Input image
←	outImage	Image&		Output image

Errors

List of possible exceptions:

Error type	Description
DomainError	Unsupported depth. Only single-channel images are supported.
DomainError	Unsupported pixel format. Only UInt16 images are supported.

Photoneo_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Triggers software trigger.

Syntax

```
void avl::Photoneo_GenerateSoftwareTrigger
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string

Remarks

PhoXi Control

PhoXi Control process needs to run for the filters to work.

Camera Setup

It is advisable to use Photoneo_StartAcquisition filter and setup inCaptureSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely, when wrong trigger source or output type is selected.

Camera identification

When there is only one Photoneo camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one camera connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Photoneo PhoXi Control software.

Photoneo PhoXi Control can be downloaded from the following website:
https://www.photoneo.com/downloads/phoxi-control/

Supported PhoXi Control version for Aurora Vision Studio usage is **1.11.1**.

Environment variable PHOXI_CONTROL_PATH which should point to the installation folder of PhoXi Control. PHO_LOG_FILES_DIR environment variable must contain a path to accessible folder. PHO_LOG_FILES_DIR is not set automatically after SDK installation. Manual configuration of this variable may be a requirement. Failure to meet these requirements may result in unexpected termination of the application.

Rebooting computer after SDK installation is mandatory.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- Photoneo_StartAcquisition – Starts capturing data from a Photoneo camera.
- Photoneo_GrabPoint3DGrid – Captures PointCloud structure using Photoneo.

Photoneo_GetParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets the camera parameters.

Syntax

```
void avl::Photoneo_GetParameters
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 avl::PhotoneoCaptureSettings& outCaptureSettings
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	outCaptureSettings	PhotoneoCaptureSettings&		

Remarks

PhoXi Control

- Photoneo_GrabPoint3DGrid – Captures PointCloud structure using Photoneo.

Photoneo_GrabColorCameraImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures ColorCameraImage structure using Photoneo.

Syntax

```
bool avl::Photoneo_GrabColorCameraImage
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 const avl::PhotoneoCaptureSettings& inCaptureSettings,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	inCaptureSettings	const PhotoneoCaptureSettings&		
	outImage	Image&		Output image

Remarks

PhoXi Control

PhoXi Control process needs to run for the filters to work.

Camera Setup

It is advisable to use Photoneo_StartAcquisition filter and setup inCaptureSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely, when wrong trigger source or output type is selected.

Camera identification

When there is only one Photoneo camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one camera connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Photoneo PhoXi Control software.

Photoneo PhoXi Control can be downloaded from the following website:
https://www.photoneo.com/downloads/phoxi-control/

Supported PhoXi Control version for Aurora Vision Studio usage is **1.11.1**.

Environment variable PHOXI_CONTROL_PATH which should point to the installation folder of PhoXi Control. PHO_LOG_FILES_DIR environment variable must contain a path to accessible folder. PHO_LOG_FILES_DIR is not set automatically after SDK installation. Manual configuration of this variable may be a requirement. Failure to meet these requirements may result in unexpected termination of the application.

Rebooting computer after SDK installation is mandatory.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Photoneo_GrabColorCameraImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures ColorCameraImage structure using Photoneo.

Syntax

```
bool avl::Photoneo_GrabColorCameraImage_WithTimeout
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 const atl::Optional<int> inTimeout,
 const avl::PhotoneoCaptureSettings& inCaptureSettings,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	inTimeout	const Optional<int>	NIL	Timeout [ms]
	inCaptureSettings	const PhotoneoCaptureSettings&		
	outImage	Conditional<Image>&		Output image

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures Texture structure using Photoneo.

Syntax

```
bool avl::Photoneo_GrabTexture_WithTimeout
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 const atl::Optional<int> inTimeout,
 const avl::PhotoneoCaptureSettings& inCaptureSettings,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	inTimeout	const Optional<int>	NIL	Timeout [ms]
	inCaptureSettings	const PhotoneoCaptureSettings&		
	outImage	Conditional<Image>&		Output image

Remarks

PhoXi Control

PhoXi Control process needs to run for the filters to work.

Camera Setup

It is advisable to use Photoneo_StartAcquisition filter and setup inCaptureSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely, when wrong trigger source or output type is selected.

Camera identification

When there is only one Photoneo camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one camera connected to the computer.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Photoneo PhoXi Control software.

Photoneo PhoXi Control can be downloaded from the following website:
https://www.photoneo.com/downloads/phoxi-control/

Supported PhoXi Control version for Aurora Vision Studio usage is **1.11.1**.

Environment variable PHOXI_CONTROL_PATH which should point to the installation folder of PhoXi Control. PHO_LOG_FILES_DIR environment variable must contain a path to accessible folder. PHO_LOG_FILES_DIR is not set automatically after SDK installation. Manual configuration of this variable may be a requirement. Failure to meet these requirements may result in unexpected termination of the application.

Rebooting computer after SDK installation is mandatory.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Photoneo_SetParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the camera parameters.

Syntax

```
void avl::Photoneo_SetParameters
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 const avl::PhotoneoCaptureSettings& inCaptureSettings
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	inCaptureSettings	const PhotoneoCaptureSettings&

Photoneo_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts capturing data from a Photoneo camera.

Applications: Typically used for establishing camera connectivity before the first trigger event. Especially important for multiple-camera systems.

Syntax

```
void avl::Photoneo_StartAcquisition
(
 Photoneo_State& ioState,
 const atl::Optional<atl::String> inDeviceID,
 const avl::PhotoneoCaptureSettings& inCaptureSettings
)
```

Parameters

	Name	Type	Default	Description
	ioState	Photoneo_State&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>	NIL	Device identification string
	inCaptureSettings	const PhotoneoCaptureSettings&

Pylon_ExecuteCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes command in Basler device.

Syntax

```
void avl::Pylon_ExecuteCommand
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inCommandName
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inCommandName	const String&		Name of feature parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description

Pylon_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::Pylon_GenerateSoftwareTrigger
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 bool inIgnoreWaiting,
 atl::Optional<int> inTimeout,
 bool& outExecuted
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Pylon_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Serial number, model name, user defined name or full name of camera device to be opened
→	inIgnoreWaiting	bool			Waiting for previous trigger doesn't work with all cameras. E.g. for models A600 this value should be set to true.
→	inTimeout	Optional<int>	100 – ∞	NIL	
←	outExecuted	bool&			Use only if inTimeout is set

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool.

Syntax

```
void avl::Pylon_GetBoolParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	outValue	bool&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enumeration.

Syntax

```
void avl::Pylon_GetEnumParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	outValue	String&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetGigEStatistics

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GigeVision device statistics data.

Syntax

```
void avl::Pylon_GetGigEStatistics
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::int64& outTotalBufferCount,
 atl::int64& outFailedBufferCount,
 atl::int64& outBufferUnderrunCount,
 atl::int64& outTotalPacketCount,
 atl::int64& outFailedPacketCount,
 atl::int64& outResendRequestCount,
 atl::int64& outResendPacketCount,
 atl::int64& outNumEmptyBuffers,
 atl::int64& outNumQueuedBuffers,
 atl::int64& outNumReadyBuffers,
 atl::int64& outOutputQueueSize
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	outTotalBufferCount	int64&		Counts the number of received frames
	outFailedBufferCount	int64&		Counts the number of buffers with at least one failed packet (status != success)
	outBufferUnderrunCount	int64&		Counts the number of frames lost because there were no buffers queued to the driver
	outTotalPacketCount	int64&		Counts the number of received packets
	outFailedPacketCount	int64&		Counts the number of failed packets (status != success)
	outResendRequestCount	int64&		Counts the number of emitted PACKETRESEND commands
	outResendPacketCount	int64&		Counts the number of packets requested by PACKETRESEND commands
	outNumEmptyBuffers	int64&		The number of empty buffers that are not used for grabbing yet
	outNumQueuedBuffers	int64&		The number of buffers queued at Low Level API stream grabber
	outNumReadyBuffers	int64&		The number of grab result buffers in the output queue that are ready for retrieval
	outOutputQueueSize	int64&		The size of the grab result buffer output queue

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::Pylon_GetIntegerParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Pylon_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	int&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Real.

Syntax

```
void avl::Pylon_GetRealParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Pylon_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	float&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::Pylon_GetStringParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Pylon_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	String&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_GetUsbStatistics

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets GigeVision device statistics data.

Syntax

```
void avl::Pylon_GetUsbStatistics
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::int64& outTotalBufferCount,
 atl::int64& outFailedBufferCount,
 atl::int64& outLastFailedBufferStatus,
 atl::String& outLastFailedBufferStatusText,
 atl::int64& outMissedFrameCount,
 atl::int64& outResynchronizationCount,
 atl::int64& outLastBlockId,
 atl::int64& outNumEmptyBuffers,
 atl::int64& outNumQueuedBuffers,
 atl::int64& outNumReadyBuffers,
 atl::int64& outOutputQueueSize
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Pylon_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
←	outTotalBufferCount	int64&		The total count of processed buffers
←	outFailedBufferCount	int64&		The count of buffers that returned with an error status
←	outLastFailedBufferStatus	int64&		The status code of the last failed buffer
←	outLastFailedBufferStatusText	String&		The message text of the status code of the last failed buffer
←	outMissedFrameCount	int64&		The count of bad or missed frames between successfully grabbed images
←	outResynchronizationCount	int64&		The count of stream resynchronizations
←	outLastBlockId	int64&		The last grabbed block ID
←	outNumEmptyBuffers	int64&		The number of empty buffers that are not used for grabbing yet
←	outNumQueuedBuffers	int64&		The number of buffers queued at Low Level API stream grabber
←	outNumReadyBuffers	int64&		The number of grab result buffers in the output queue that are ready for retrieval
←	outOutputQueueSize	int64&		The size of the grab result buffer output queue

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

Also in AVL Lite

Pylon_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image stream from a camera using Pylon library.

Syntax

```
bool avl::Pylon_GrabImage
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inOutputQueueSize,
 atl::Optional<avl::PylonImageFormat::Type> inPixelFormat,
 atl::Optional<float> inFrameRate,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<float> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<float> inBlackLevel,
 atl::Optional<bool> inTriggerEnabled,
 atl::Optional<avl::PylonTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::PylonTriggerActivation::Type> inTriggerActivation,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Pylon_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Serial number, model name, user defined name or full name of camera device to be opened
→	inOutputQueueSize	int	1 – 200	3	Capacity of output frames queue
→	inPixelFormat	Optional<PylonImageFormat::Type>		NIL	Image pixel format
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream. To reset AOI set Box(0,0,0,0).
→	inExposureTime	Optional<float>	0.0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – ∞	NIL	Analog gain of source image in device raw unit
→	inBlackLevel	Optional<float>	0.0 – ∞	NIL	Black level of source image
→	inTriggerEnabled	Optional<bool>		NIL	Configure trigger enable
→	inTriggerSource	Optional<PylonTriggerSource::Type>		NIL	Source of acquisition trigger
→	inTriggerActivation	Optional<PylonTriggerActivation::Type>		NIL	Circumstances defining when the trigger is activated
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Captured frame ID
←	outTimestamp	int64&			Captured frame timestamp

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Pylon SDK software with camera dedicated drivers.

Pylon SDK can be downloaded from the following website: https://www2.baslerweb.com/en/downloads/software-downloads/#type=pylonsoftware;language=all;version=7.4.0 (registration may be required).

Recommended Pylon SDK version for Aurora Vision Studio usage is **7.4.0**.

Other SDK versions from the same family (for example 7.4.1) can be compatible with Aurora Vision Studio but correct operation is not guaranteed.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – should be specified on device casing, for example "12345678".
- **User defined name** – user defined device name.
- **Friendly name** – human readable name of the device.
- **Device full name** – full name identifying the device.
- **Model name** – model name of the device.
- **Ip Address** – camera IP address. Only for GigEVision cameras.

Camera parameters

Setting **inAoi** parameter to 'Auto' will select maximum possible camera frame size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use configuration tool "Pylon Viewer" available with Pylon SDK or Pylon_SetXXXParameter filters. Refer to Pylon documentation to find information about parameters and how to create user parameters sets.

Output outFrameId

- **GigE Camera Devices** – The sequence number starts with 1 and wraps at 65535. The value 0 has a special meaning and indicates that this feature is not supported by the camera.
- **USB Camera Devices** – The sequence number starts with 0 and uses the full 64 Bit range.

A block ID of value -1 indicates that the Block ID is invalid and must not be used.

Output outTimeStamp

In case of GigE-Vision this describes when the image exposure was started. Cameras that do not support this feature return zero. If supported this may be used to determine which ROIs were acquired simultaneously.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

See Also

- Pylon_GrabImage_WithTimeout – Captures an image stream from a camera using Pylon library; returns Nil if no frame comes in the specified time.
- Pylon_StartAcquisition – Initializes and starts image acquisition in a camera.

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image stream from a camera using Pylon library; returns Nil if no frame comes in the specified time.

Syntax

```
bool avl::Pylon_GrabImage_WithTimeout
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inOutputQueueSize,
 int inTimeout,
 atl::Optional<avl::PylonImageFormat::Type> inPixelFormat,

Pylon SDK can be downloaded from the following website: https://www2.baslerweb.com/en/downloads/software-downloads/#type=pylonsoftware;language=all;version=7.4.0 (registration may be required).

Recommended Pylon SDK version for Aurora Vision Studio usage is **7.4.0**.

Other SDK versions from the same family (for example 7.4.1) can be compatible with Aurora Vision Studio but correct operation is not guaranteed.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – should be specified on device casing, for example "12345678".
- **User defined name** – user defined device name.
- **Friendly name** – human readable name of the device.
- **Device full name** – full name identifying the device.
- **Model name** – model name of the device.
- **Ip Address** – camera IP address. Only for GigEVision cameras.

Camera parameters

Setting **inAoi** parameter to 'Auto' will select maximum possible camera frame size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use configuration tool "Pylon Viewer" available with Pylon SDK or Pylon_SetXXXParameter filters. Refer to Pylon documentation to find information about parameters and how to create user parameters sets.

Output outFrameId

- **GigE Camera Devices** – The sequence number starts with 1 and wraps at 65535. The value 0 has a special meaning and indicates that this feature is not supported by the camera.
- **USB Camera Devices** – The sequence number starts with 0 and uses the full 64 Bit range.

A block ID of value -1 indicates that the Block ID is invalid and must not be used.

Output outTimeStamp

In case of GigE-Vision this describes when the image exposure was started. Cameras that do not support this feature return zero. If supported this may be used to determine which ROIs were acquired simultaneously.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

Pylon_SetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Bool.

Syntax

```
void avl::Pylon_SetBoolParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	bool		New value to be set into device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Enumeration.

Syntax

```
void avl::Pylon_SetEnumParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_SetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Integer.

Syntax

```
void avl::Pylon_SetIntegerParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	int		New value to be set into device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_SetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Real.

Syntax

```
void avl::Pylon_SetRealParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	float		New value to be set into device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_SetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type String.

Syntax

```
void avl::Pylon_SetStringParameter
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_SetUserOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets Basler camera user output.

Syntax

```
void avl::Pylon_SetUserOutput
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::PylonUserOutput::Type inUserOutput,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Serial number, model name, user defined name or full name of camera device to be opened
	inUserOutput	PylonUserOutput::Type		
	inValue	bool		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

Pylon_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::Pylon_StartAcquisition
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inOutputQueueSize,
 atl::Optional<avl::PylonImageFormat::Type> inPixelFormat,
 atl::Optional<float> inFrameRate,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<float> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<float> inBlackLevel,
 atl::Optional<bool> inTriggerEnabled,
 atl::Optional<avl::PylonTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::PylonTriggerActivation::Type> inTriggerActivation
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Pylon_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Serial number, model name, user defined name or full name of camera device to be opened
→	inOutputQueueSize	int	1 – 200	3	Capacity of output frames queue
→	inPixelFormat	Optional<PylonImageFormat::Type>		NIL	Image pixel format
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream. To reset AOI set Box(0,0,0,0).
→	inExposureTime	Optional<float>	0.0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – ∞	NIL	Analog gain of source image in device raw unit
→	inBlackLevel	Optional<float>	0.0 – ∞	NIL	Black level of source image
→	inTriggerEnabled	Optional<bool>		NIL	Configure trigger enable
→	inTriggerSource	Optional<PylonTriggerSource::Type>		NIL	Source of acquisition trigger
→	inTriggerActivation	Optional<PylonTriggerActivation::Type>		NIL	Circumstances defining when the trigger is activated

Remarks

This filter is intended for establishing connection with a Basler camera device using Pylon interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of Pylon_GrabImage or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. Pylon_GrabImage or Pylon_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke. When this filter is used, the **inPixelFormat** parameter of subsequent Pylon_GrabImage and Pylon_GrabImage_WithTimeout] filters has no effect.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Pylon SDK software with camera dedicated drivers.

Pylon SDK can be downloaded from the following website:
https://www2.baslerweb.com/en/downloads/software-downloads/#type=pylonsoftware;language=all;version=7.4.0 (registration may be required).

Recommended Pylon SDK version for Aurora Vision Studio usage is **7.4.0**.

Other SDK versions from the same family (for example 7.4.1) can be compatible with Aurora Vision Studio but correct operation is not guaranteed.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial number** – should be specified on device casing, for example "12345678".
- **User defined name** – user defined device name.
- **Friendly name** – human readable name of the device.
- **Device full name** – full name identifying the device.
- **Model name** – model name of the device.
- **Ip Address** – camera IP address. Only for GigEVision cameras.

Camera parameters

Setting **inAoi** parameter to 'Auto' will select maximum possible camera frame size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use configuration tool "Pylon Viewer" available with Pylon SDK or Pylon_SetXXXParameter filters. Refer to Pylon documentation to find information about parameters and how to create user parameters sets.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Not implemented

See Also

- Pylon_GrabImage – Captures an image stream from a camera using Pylon library.
- Pylon_GrabImage_WithTimeout – Captures an image stream from a camera using Pylon library; returns Nil if no frame comes in the specified time.

Pylon_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::Pylon_StopAcquisition
(
 Pylon_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Pylon_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Serial number, model name, user defined name or full name of camera device to be opened

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Platform support

This operation is not supported on ARM processor architecture systems.

RealSense_GrabColorImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a RGB image using RealSense.

Syntax

```
bool avl::RealSense_GrabColorImage
(
 RealSense_State& ioState,
 const atl::Optional<atl::File>& inConfigFile,
 const atl::Optional<atl::String>& inSerial,
 atl::Optional<int> inConnectionTimeout,
 int inInputQueueSize,
 const atl::Optional<avl::RealSenseRGBConfiguration>& inRGBSettings,
 const atl::Optional<avl::RealSenseDepthConfiguration>& inDepthSettings,
 const atl::Optional<avl::RealSensePostProcessingFilters>& inPostProcessingSettings,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	RealSense_State&			Object used to maintain state of the function.
→	inConfigFile	const Optional<File>&		NIL	Configuration file with the .json extension
→	inSerial	const Optional<String>&		NIL	Device serial number
→	inConnectionTimeout	Optional<int>		NIL	Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inRGBSettings	const Optional<RealSenseRGBConfiguration>&		NIL	Settings for RGB stream
→	inDepthSettings	const Optional<RealSenseDepthConfiguration>&		NIL	Settings for Depth and Infrared streams
→	inPostProcessingSettings	const Optional<RealSensePostProcessingFilters>&		NIL	Post-processing filters to choose
←	outImage	Image&			Output image

Remarks

Camera Setup

First, make sure that the camera is connected to the USB3 port. It is advisable to use RealSense_StartAcquisition filter and setup inRGBSettings, inDepthSettings, inPostProcessingSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely.

Camera identification

When there is only one RealSense camera connected, the field **inSerial** can be set to Auto. In this situation, the first available camera will be used.

inSerial can be used to pick one camera connected to the computer, you can check the camera's serial number, for example, in the manufacturer's Intel RealSense Viewer application.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Intel RealSense SDK 2.0 (v2.55.1).

Intel RealSense SDK can be downloaded from the following website:
https://github.com/IntelRealSense/librealsense/releases/tag/v2.55.1

Supported Intel RealSense SDK version for Aurora Vision Studio usage is **2.55.1**.

Environment variable to the .dll file is not set automatically after SDK installation. Manual configuration of this variable may be a requirement. Failure to meet these requirements may result in unexpected termination of the application.

If the SDK was installed in the default location, the following folder should be indicated in the environment variable: "C:\Program Files (x86)\Intel RealSense SDK 2.0\bin\x64".

You may need to restart your computer after installing the SDK.

Support limitations

Filters were tested on the model: Intel RealSense D455. For other models in the series, the filters may not work properly or will not have additional functionalities.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

RealSense_GrabInfraredImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a infrared image using RealSense.

Syntax

```
bool avl::RealSense_GrabInfraredImage
(
 RealSense_State& ioState,
 const atl::Optional<atl::File>& inConfigFile,
 const atl::Optional<atl::String>& inSerial,
 atl::Optional<int> inConnectionTimeout,
 int inInputQueueSize,
 const atl::Optional<avl::RealSenseRGBConfiguration>& inRGBSettings,
 const atl::Optional<avl::RealSenseDepthConfiguration>& inDepthSettings,
 const atl::Optional<avl::RealSensePostProcessingFilters>& inPostProcessingSettings,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	RealSense_State&			Object used to maintain state of the function.
→	inConfigFile	const Optional<File>&		NIL	Configuration file with the .json extension
→	inSerial	const Optional<String>&		NIL	Device serial number
→	inConnectionTimeout	Optional<int>		NIL	Maximum time to wait for frames in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inRGBSettings	const Optional<RealSenseRGBConfiguration>&		NIL	Settings for RGB stream
→	inDepthSettings	const Optional<RealSenseDepthConfiguration>&		NIL	Settings for Depth and Infrared streams
→	inPostProcessingSettings	const Optional<RealSensePostProcessingFilters>&		NIL	Post-processing filters to choose
←	outImage	Image&			Output image

Remarks

Camera Setup

First, make sure that the camera is connected to the USB3 port. It is advisable to use RealSense_StartAcquisition filter and setup inRGBSettings, inDepthSettings, inPostProcessingSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely.

Camera identification

When there is only one RealSense camera connected, the field **inSerial** can be set to Auto. In this situation, the first available camera will be used.

inSerial can be used to pick one camera connected to the computer, you can check the camera's serial number, for example, in the manufacturer's Intel RealSense Viewer application.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Intel RealSense SDK 2.0 (v2.55.1).

Intel RealSense SDK can be downloaded from the following website:
https://github.com/IntelRealSense/librealsense/releases/tag/v2.55.1

Supported Intel RealSense SDK version for Aurora Vision Studio usage is **2.55.1**.

Environment variable to the .dll file is not set automatically after SDK installation. Manual configuration of this variable may be a requirement. Failure to meet these requirements may result in unexpected termination of the application.

If the SDK was installed in the default location, the following folder should be indicated in the environment variable: "C:\Program Files (x86)\Intel RealSense SDK 2.0\bin\x64".

You may need to restart your computer after installing the SDK.

Support limitations

Filters were tested on the model: Intel RealSense D455. For other models in the series, the filters may not work properly or will not have additional functionalities.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

RealSense_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts acquisition using Intel RealSense.

Syntax

```
void avl::RealSense_StartAcquisition
(
 RealSense_State& ioState,
 const atl::Optional<atl::File>& inConfigFile,
 const atl::Optional<atl::String>& inSerial,
 atl::Optional<int> inConnectionTimeout,
 int inInputQueueSize,
 const atl::Optional<avl::RealSenseRGBConfiguration>& inRGBSettings,
 const atl::Optional<avl::RealSenseDepthConfiguration>& inDepthSettings,
 const atl::Optional<avl::RealSensePostProcessingFilters>& inPostProcessingSettings
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	RealSense_State&			Object used to maintain state of the function.
→	inConfigFile	const Optional<File>&		NIL	Configuration file with the .json extension
→	inSerial	const Optional<String>&		NIL	Device serial number
→	inConnectionTimeout	Optional<int>		NIL	Maximum time to wait for frames in milliseconds
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inRGBSettings	const Optional<RealSenseRGBConfiguration>&		NIL	Settings for RGB stream
→	inDepthSettings	const Optional<RealSenseDepthConfiguration>&		NIL	Settings for Depth and Infrared streams
→	inPostProcessingSettings	const Optional<RealSensePostProcessingFilters>&		NIL	Post-processing filters to choose

Remarks

This filter is intended for establishing connection with a RealSense camera device using Intel RealSense SDK, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera before the first invoke.

The use of this filter is not obligatory. For example RealSense_GrabColorImage or RealSense_GrabColorImage_WithTimeout filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera Setup

First, make sure that the camera is connected to the USB3 port. It is advisable to use RealSense_StartAcquisition filter and setup inRGBSettings, inDepthSettings, inPostProcessingSettings with proper values. Some values might not be set to values the user expects and acquisition will fail or wait infinitely.

Camera identification

When there is only one RealSense camera connected, the field **inSerial** can be set to Auto. In this situation, the first available camera will be used.

Roseek_ConfigureLEDDriverMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the driver working mode of LED.

Syntax

```
void avl::Roseek_ConfigureLEDDriverMode
(
 Roseek_State& ioState,
 avl::RoseekLEDDriverType::Type inType,
 avl::RoseekLEDDriverMode::Type inMode
)
```

Parameters

	Name	Type	Default	Description
	ioState	Roseek_State&		Object used to maintain state of the function.
	inType	RoseekLEDDriverType::Type		Driver type (own or external)
	inMode	RoseekLEDDriverMode::Type		LED driver mode

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::Roseek_GenerateSoftwareTrigger
(
 Roseek_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Roseek_State&		Object used to maintain state of the function.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_GetInputState

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets input I/O state.

Syntax

```
void avl::Roseek_GetInputState
(
 Roseek_State& ioState,
 int inId,
 bool& outState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Roseek_State&			Object used to maintain state of the function.
	inId	int	0 - 7		Index of I/O output port
	outState	bool&			Received state

Remarks

Camera driver software

Also in AVL Lite

Roseek_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Roseek device.

Syntax

```
bool avl::Roseek_GrabImage
(
 Roseek_State& ioState,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 avl::Image& outImage,
 int& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Roseek_State&			Object used to maintain state of the function.
→	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
→	inImageFormat	RoseekImageFormat::Type			Image pixel format
→	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
→	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI.
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Image&			Captured frame
←	outFrameID	int&			Captured frame ID

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Roseek_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Roseek device.

Syntax

```
bool avl::Roseek_GrabImage_WithTimeout
(
 Roseek_State& ioState,
 int inTimeout,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<int>& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Roseek_State&			Object used to maintain state of the function.
→	inTimeout	int	10 – 3600000		Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
→	inImageFormat	RoseekImageFormat::Type			Image pixel format
→	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
→	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI.
→	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int>&			Captured frame ID

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_SetLEDDriverStrength

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the driver strength of LED.

Syntax

```
void avl::Roseek_SetLEDDriverStrength
(
 Roseek_State& ioState,
 avl::RoseekLEDDriverType::Type inType,
 int inStrength
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Roseek_State&			Object used to maintain state of the function.
	inType	RoseekLEDDriverType::Type			Driver type (own or external)
	inStrength	int	0 – 1500		Strength. For OWN driver type the max value is 330 otherwise 1500

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_SetOutputState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output I/O state.

Syntax

```
void avl::Roseek_SetOutputState
(
 Roseek_State& ioState,
 int inId,
 bool inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Roseek_State&			Object used to maintain state of the function.
	inId	int	0 – 7		Index of I/O output port
	inState	bool			true = TURN_ON, false = TURN_OFF

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_SetStatusLED

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets the status of programmable LED state indicators supported on the camera.

Syntax

```
void avl::Roseek_SetStatusLED
(
 Roseek_State& ioState,
 int inId,
 avl::RoseekLEDStatus::Type inState
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Roseek_State&			Object used to maintain state of the function.
	inId	int	0 – 2		Index of I/O output port
	inState	RoseekLEDStatus::Type			Received state

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition.

Syntax

```
void avl::Roseek_StartAcquisition
(
 Roseek_State& ioState,
 int inInputQueueSize,
 avl::RoseekImageFormat::Type inImageFormat,
 atl::Optional<avl::RoseekResolutionMode::Type> inResolutionMode,
 const atl::Optional<avl::Box>& inROI,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Roseek_State&			Object used to maintain state of the function.
	inInputQueueSize	int	1 – 1000	3	Number of incoming frames that can be buffered before the application is able to process them
	inImageFormat	RoseekImageFormat::Type			Image pixel format
	inResolutionMode	Optional<RoseekResolutionMode::Type>		NIL	Set resolution of image
	inROI	const Optional<Box>&		NIL	Set resolution region. Has effect only if resolution mode is ROI
	inFrameRate	Optional<float>	0.1 – 400.0	NIL	Requested camera frame rate in frames per second
	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Roseek_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition.

Syntax

```
void avl::Roseek_StopAcquisition
(
 Roseek_State& ioState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Roseek_State&		Object used to maintain state of the function.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Roseek SDK. To be able to connect to camera it is required to install Roseek SDK software with camera dedicated drivers. Currently Aurora Vision uses **Roseek version v1.32**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- SiliconSoftware_StopAcquisition

Also in AVL Lite

SiliconSoftware_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger. This function depends on current applet.

Syntax

```
void avl::SiliconSoftware_GenerateSoftwareTrigger
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inPort	int	0 – ∞		DMA port

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SiliconSoftware_GetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Double.

Syntax

```
void avl::SiliconSoftware_GetDoubleParameter
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 int inPort,
 const atl::String& inName,
 double& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inAppletPath	Optional<const String&>		NIL	Applet to load
→	inPort	int	0 – ∞		DMA port
→	inName	const String&			Parameter name
←	outValue	double&			Parameter value

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SiliconSoftware_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::SiliconSoftware_GetIntegerParameter
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 int inPort,
 const atl::String& inName,
 int& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inAppletPath	Optional<const String&>		NIL	Applet to load
→	inPort	int	0 – ∞		DMA port
→	inName	const String&			Parameter name
←	outValue	int&			Parameter value

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

SiliconSoftware_GetParametersList

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns list of all parameter available on current applet.

Syntax

```
void avl::SiliconSoftware_GetParametersList
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 atl::Array<atl::String>& outNames,
 atl::Array<atl::String>& outTypes
)
```

Parameters

	Name	Type	Range	Default	Description
⇄	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inAppletPath	Optional<const String&>		NIL	Applet to load
←	outNames	Array<String>&			Parameters name
←	outTypes	Array<String>&			Parameters type

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SiliconSoftware_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::SiliconSoftware_GetStringParameter
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 int inPort,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inAppletPath	Optional<const String&>		NIL	Applet to load
	inPort	int	0 – ∞		DMA port
	inName	const String&			Parameter name
	outValue	String&			Parameter value

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SiliconSoftware_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Silicon Software board.

Syntax

```
bool avl::SiliconSoftware_GrabImage
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 int inPort,
 int inInputQueueSize,
 atl::Optional<const atl::File&> inConfigurationFile,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inAppletPath	Optional<const String&>		NIL	Applet to load
	inPort	int	0 – ∞		DMA port
	inInputQueueSize	int	4 – 200	5	Capacity of output frames queue
	inConfigurationFile	Optional<const File&>		NIL	Configuration file path
	outImage	Image&			Captured frame

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** - Silicon Software board identifying internal index.

Frame grabber driver software

This filter is intended to cooperate with a microEnable using its vendor SDK. To be able to connect to a device, it is required to install Silicon Software Runtime with frame grabber dedicated drivers. We also recommended install version with applets.

Silicon Software Runtime can be downloaded from the following website: https://silicon.software/product/microenable-5-acl-marathon/.

Add DLL path to system environment variable may be required.

Recommended Runtime version for Aurora Vision Studio usage is **5.7.0**.

Load applets to device memory may be needed for some devices. Please use RT microDisplay software for this purpose.

Each frame grabber is initializing master mode. Acquisition is started in non blocking mode.

Device parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

Setting **inAppletPath** parameter to 'Auto' will select currently loaded and activated applet.

Setting **inConfigurationFile** is recommended way to configure acquisition properties instead of SiliconSoftware_SetParameter function.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

List of available parameters, including acquisition triggering, depends on applet type and will contains custom options. You can find it in device vendor documentation and current selected applet documentation.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

SiliconSoftware_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using Silicon Software board.

Syntax

```
bool avl::SiliconSoftware_GrabImage_WithTimeout
(
 SiliconSoftware_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Optional<const atl::String&> inAppletPath,
 int inPort,
 int inTimeout,
 int inInputQueueSize,
 atl::Optional<const atl::File&> inConfigurationFile,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SiliconSoftware_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inAppletPath	Optional<const String&>		NIL	Applet to load
→	inPort	int	0 – ∞		DMA port
→	inTimeout	int	1 – ∞	2	Maximum time to wait for frame in seconds
→	inInputQueueSize	int	4 – 200	5	Capacity of output frames queue
→	inConfigurationFile	Optional<const File&>		NIL	Configuration file path
←	outImage	Conditional<Image>&			Captured frame

Remarks

Remarks

Device identification

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - SmartRay Device identifying IP address (e.g. "127.0.0.1")

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install SmartRay SDK software with camera dedicated drivers.

Add DLL path to system environment variable may be required.

Recommended SmartRay SDK version for Aurora Vision Studio usage is **6.0.11.13**.

Firmware updates might be required for older scanners to work with SDK version 6.x. In this case, please contact SmartRay support.

Disable firewall software and set 192.168.178.100 static IP in your network interface may be needed.

ECCO 35 and ECCO 55 series

Using SmartRay_LoadParameterSet before start acquisition or grab filter for this devices may be mandatory.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

SmartRay_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures with timeout a live image using SmartRay.

Syntax

```
bool avl::SmartRay_GrabImage_WithTimeout
(
 SmartRay_State& ioState,
 const atl::String& inAddress,
 int inPort,
 int inConnectionTimeout,
 int inInputQueueSize,
 const atl::Optional<int> inTimeout,
 const avl::SmartRayDataTrigger& inDataTrigger,
 atl::Optional<const avl::SmartRayRegionOfInterest&> inRegionOfInterest,
 atl::Optional<const avl::SmartRayExposure&> inExposure,
 atl::Optional<const avl::SmartRayLaser&> inLaser,
 atl::Optional<const avl::SmartRayStartTrigger&> inStartTrigger,
 atl::Optional<const avl::SmartRayReflectionFilter&> inReflectionFilter,
 atl::Optional<const atl::Array<int>&> inLaserLineThreshold,
 atl::Optional<int> inMinLaserLineThicknessLimit,
 atl::Optional<int> inMaxLaserLineThicknessLimit,

	ioState	SmartRay_State&			Object used to maintain state of the function.
	inAddress	const String&		\"192.168.178.200\"	Device identifying address
	inPort	int		40	Device identifying network port
	inConnectionTimeout	int	1 - 1000	60	Timeout in seconds
	inFile	const File&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

SmartRay_LoadSmartXtractPreset

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Loads SmartXtract preset data from file to SmartRay device.

Syntax

```
void avl::SmartRay_LoadSmartXtractPreset
(
 SmartRay_State& ioState,
 const atl::String& inAddress,
 int inPort,
 int inConnectionTimeout,
 const atl::File& inFile
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SmartRay_State&			Object used to maintain state of the function.
	inAddress	const String&		\"192.168.178.200\"	Device identifying address
	inPort	int		40	Device identifying network port
	inConnectionTimeout	int	1 - 1000	60	Timeout in second
	inFile	const File&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SmartRay_MeanFilter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

SmartRay mean filter.

Syntax

```
void avl::SmartRay_MeanFilter
(
 SmartRay_UtilityState& ioState,
 int inKernelSizeX,
 int inKernelSizeY,
 int inExcludeZeros,
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	SmartRay_UtilityState&		Object used to maintain state of the function.
	inKernelSizeX	int	5	
	inKernelSizeY	int	5	
	inExcludeZeros	int		
	inImage	const Image&		Input image
	outImage	Image&		Output image

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SmartRay_MedianFilter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

SmartRay median filter.

Syntax

```
void avl::SmartRay_MedianFilter
(
 SmartRay_UtilityState& ioState,
 int inKernelSizeX,
 int inKernelSizeY,
 int inExcludeZeros,
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	SmartRay_UtilityState&		Object used to maintain state of the function.
	inKernelSizeX	int	5	
	inKernelSizeY	int	5	
	inExcludeZeros	int		
	inImage	const Image&		Input image
	outImage	Image&		Output image

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

SmartRay_SetDigitalOutput

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital output of SmartRay device.

Syntax

```
void avl::SmartRay_SetDigitalOutput
(
 SmartRay_State& ioState,
 const atl::String& inAddress,
 int inPort,
 int inConnectionTimeout,
 int inChannel,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SmartRay_State&			Object used to maintain state of the function.
	inAddress	const String&		\"192.168.178.200\"	Device identifying address
	inPort	int		40	Device identifying network port
	inConnectionTimeout	int	1 - 1000	60	Timeout in seconds
	inChannel	int	1 - 2		
	inEnable	bool			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SmartRay_SmoothImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

SmartRay smooth filter dedicated to 3D vision .

Syntax

```
void avl::SmartRay_SmoothImage
(
 SmartRay_UtilityState& ioState,
 avl::SmartRaySmoothImageAlgorithm::Type inSmoothAlgorithm,
 const avl::Image& inImage,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	SmartRay_UtilityState&		Object used to maintain state of the function.
	inSmoothAlgorithm	SmartRaySmoothImageAlgorithm::Type		
	inImage	const Image&		Input image
	outImage	Image&		Output image

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

SmartRay_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts acquisition using SmartRay.

Syntax

```
void avl::SmartRay_StartAcquisition
(
 SmartRay_State& ioState,
 const atl::String& inAddress,
 int inPort,
 int inConnectionTimeout,
 int inInputQueueSize,
 float inTransportResolution,
 int inNumberOfProfiles,
 atl::Optional<const atl::File&> inCalibrationFile,
 avl::SmartRayImageAcquisitionType::Type inAcquisitionType,
 const avl::SmartRayDataTrigger& inDataTrigger,
 atl::Optional<const avl::SmartRayRegionOfInterest&> inRegionOfInterest,
 atl::Optional<const avl::SmartRayExposure&> inExposure,
 atl::Optional<const avl::SmartRayLaser&> inLaser,
 atl::Optional<const avl::SmartRayStartTrigger&> inStartTrigger,
 atl::Optional<const avl::SmartRayReflectionFilter&> inReflectionFilter,
 atl::Optional<const atl::Array<int>&> inLaserLineThreshold,
 atl::Optional<const avl::SmartRayZmapResolution&> inZmapResolution,
 atl::Optional<int> inMinLaserLineThicknessLimit,
 atl::Optional<int> inMaxLaserLineThicknessLimit,
 atl::Optional<bool> inSmartXtract,
 atl::Optional<avl::SmartRaySmartXtractAlgorithm::Type> inSmartXtractAlgorithm,
 atl::Optional<avl::SmartRaySmartXactMode::Type> inSmartXactMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SmartRay_State&			Object used to maintain state of the function.
	inAddress	const String&		\"192.168.178.200\"	Device identifying address
	inPort	int		40	Device identifying network port
	inConnectionTimeout	int	1 – 1000	60	Timeout in seconds
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inTransportResolution	float	0.0 – ∞	1.0f	Defines x-axis step for every profile
	inNumberOfProfiles	int		10	Number of profiles to capture
	inCalibrationFile	Optional<const File&>		NIL	Do not set file to load data from device internal memory
	inAcquisitionType	SmartRayImageAcquisitionType::Type			
	inDataTrigger	const SmartRayDataTrigger&			
	inRegionOfInterest	Optional<const SmartRayRegionOfInterest&>		NIL	
	inExposure	Optional<const SmartRayExposure&>		NIL	
	inLaser	Optional<const SmartRayLaser&>		NIL	
	inStartTrigger	Optional<const SmartRayStartTrigger&>		NIL	
	inReflectionFilter	Optional<const SmartRayReflectionFilter&>		NIL	
	inLaserLineThreshold	Optional<const Array<int>&>		NIL	
	inZmapResolution	Optional<const SmartRayZmapResolution&>		NIL	
	inMinLaserLineThicknessLimit	Optional<int>		NIL	
	inMaxLaserLineThicknessLimit	Optional<int>		NIL	
	inSmartXtract	Optional<bool>		NIL	
	inSmartXtractAlgorithm	Optional<SmartRaySmartXtractAlgorithm::Type>		NIL	
	inSmartXactMode	Optional<SmartRaySmartXactMode::Type>		NIL	

Remarks

Device identification

inAddress can be used to pick one of multiple devices connected to the computer. **inAddress** can be set to:

- **IP Address** - SmartRay Device identifying IP address (e.g. "127.0.0.1")

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install SmartRay SDK software with camera dedicated drivers.

Add DLL path to system environment variable may be required.

Recommended SmartRay SDK version for Aurora Vision Studio usage is **6.0.11.13**.

Firmware updates might be required for older scanners to work with SDK version 6.x. In this case, please contact SmartRay support.

Disable firewall software and set 192.168.178.100 static IP in your network interface may be needed.

ECCO 35 and ECCO 55 series

Using SmartRay_LoadParameterSet before start acquisition or grab filter for this devices may be mandatory.

Camera parameters

Setting **inInputQueueSize** parameter to 'Auto' will select four value as input queue size.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- SmartRay_StartAcquisition - Starts acquisition using SmartRay.

SmartRay_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops acquisition using SmartRay.

Syntax

```
void avl::SmartRay_StopAcquisition
(
 SmartRay_State& ioState,
 const atl::String& inAddress,
 int inPort,
 int inConnectionTimeout
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SmartRay_State&			Object used to maintain state of the function.
	inAddress	const String&		\"192.168.178.200\"	Device identifying address
	inPort	int		40	Device identifying network port
	inConnectionTimeout	int	1 - 1000	60	

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Smart_ConfigureDigitalIO_SynView

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configure SynView digital IO.

Syntax

```
void avl::Smart_ConfigureDigitalIO_SynView
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineNumber,
 atl::Optional<bool> inLineInverter,
 atl::Optional<float> inLineDebounceDuration,
 atl::Optional<avl::SynViewLineSource::Type> inLineSource,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Smart_State&			Object used to maintain state of the function.
	inIpAddress	const SmartIPAddress&			
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inLineNumber	int	1 – 32		I/O line for configuration
	inLineInverter	Optional<bool>		NIL	Invert the signal on the selected line
	inLineDebounceDuration	Optional<float>		NIL	Input line debounce duration in us (0 for disable debouncer)
	inLineSource	Optional<SynViewLineSource::Type>		NIL	Selects a device internal signal that should drive the output signal of the selected line.
	outIsRemote	bool&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_ConfigureDigitalIO_SynView is not supported in the Lite edition.

Smart_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a smart camera using AvSMART interface. Allows for remote access to the runtime system.

Syntax

```
bool avl::Smart_GrabImage
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 avl::RoseekImageFormat::Type inPixelFormat,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 avl::Image& outImage,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Smart_State&			Object used to maintain state of the function.
→	inIpAddress	const SmartIPAddress&			IP address of the runtime system (e.g. a smart camera)
→	inPixelFormat	RoseekImageFormat::Type			Image color format
→	inFrameRate	Optional<float>		NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Image&			Captured frame
←	outIsRemote	bool&			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_GrabImage is not supported in the Lite edition.

Smart_GrabImage_GenICam

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a smart camera. Allows for remote access to the runtime system.

Syntax

```
bool avl::Smart_GrabImage_GenICam
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 atl::Optional<const avl::GenAddress&> inDeviceID,
 atl::Optional<avl::RemoteGrabberPixelFormat::Type> inPixelFormat,
 avl::Image& outImage,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
	ioState	Smart_State&		Object used to maintain state of the function.
	inIpAddress	const SmartIPAddress&		IP address of the runtime system (e.g. a smart camera)
	inDeviceID	Optional<const GenAddress&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inPixelFormat	Optional<RemoteGrabberPixelFormat::Type>	NIL	
	outImage	Image&		Captured frame
	outIsRemote	bool&		

Hints

- Check the IP address of your runtime system (e.g. using the "ipconfig" command) and set it to the **inIpAddress** input.
- Set an appropriate **inPixelFormat**.
- Run the program on you runtime system and the camera filter will acquire images directly on it.
- Run the program on your development machine (e.g. your laptop) connected to the same Ethernet and the camera filter will receive images through a connection with the runtime system.

Troubleshooting:

- Turn off the firewall on the device where the runtime system is launched.
- Check the **inDeviceID** parameter and either select the GenTL device from the manager ([...] icon on the right) or manually set the parameters if the GenTL is not available (plus icon on the left). In this case you have to fill in all the positions on the list (**inDeviceID.VendorName**, **inDeviceID.TLType**, **inDeviceID.DeviceID**).

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_GrabImage_GenICam is not supported in the Lite edition.

Smart_GrabImage_Roseek

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a smart camera using Roseek interface. Allows for remote access to the runtime system.

Syntax

```
bool avl::Smart_GrabImage_Roseek
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 avl::RoseekImageFormat::Type inPixelFormat,
 atl::Optional<float> inFrameRate,
 atl::Optional<avl::RoseekWorkingMode::Type> inWorkingMode,
 atl::Optional<int> inSensitivityLevel,
 atl::Optional<avl::RoseekExposureMode::Type> inExposureMode,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 avl::Image& outImage,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Smart_State&			Object used to maintain state of the function.
→	inIpAddress	const SmartIPAddress&			IP address of the runtime system (e.g. a smart camera)
→	inPixelFormat	RoseekImageFormat::Type			Image color format
→	inFrameRate	Optional<float>		NIL	Requested camera frame rate in frames per second
→	inWorkingMode	Optional<RoseekWorkingMode::Type>		NIL	Working mode of image acquisition
→	inSensitivityLevel	Optional<int>	0 – 3	NIL	Sensitivity level of camera sensor
→	inExposureMode	Optional<RoseekExposureMode::Type>		NIL	Exposure mode, should be set to Manual if you want to adjust inExposureTime manually
→	inExposureTime	Optional<int>	0 – ∞	NIL	Camera frame exposition time
→	inGain	Optional<float>	0.0 – 36.0	NIL	Camera exposure gain
←	outImage	Image&			Captured frame
←	outIsRemote	bool&			

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_GrabImage_Roseek is not supported in the Lite edition.

Smart_GrabImage_SynView

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a smart camera using SynView interface. Allows for remote access to the runtime system.

Syntax

```
bool avl::Smart_GrabImage_SynView
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewColorFormat::Type inPixelFormat,
 const avl::SynViewAcquisitionParams& inAcquisitionParams,
 const avl::SynViewImageFormatParams& inImageFormatParams,
 const avl::SynViewAnalogParams& inAnalogParams,
 avl::Image& outImage,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Smart_State&		Object used to maintain state of the function.
→	inIpAddress	const SmartIPAddress&		IP address of the runtime system (e.g. a smart camera)
→	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
→	inPixelFormat	SynViewColorFormat::Type		Image color format
→	inAcquisitionParams	const SynViewAcquisitionParams&		
→	inImageFormatParams	const SynViewImageFormatParams&		
→	inAnalogParams	const SynViewAnalogParams&		
←	outImage	Image&		Captured frame
←	outIsRemote	bool&		

Hints

- Check the IP address of your runtime system (e.g. using the "ipconfig" command) and set it to the **inIpAddress** input.
- Set an appropriate **inPixelFormat**.
- Run the program on you runtime system and the camera filter will acquire images directly on it.
- Run the program on your development machine (e.g. your laptop) connected to the same Ethernet and the camera filter will receive images through a connection with the runtime system.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_GrabImage_SynView is not supported in the Lite edition.

Smart_GrabImage_WebCamera

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a smart camera. Allows for remote access to the runtime system.

Syntax

```
bool avl::Smart_GrabImage_WebCamera
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 atl::Optional<int> inDeviceID,
 avl::Image& outImage,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
	ioState	Smart_State&		Object used to maintain state of the function.
	inIpAddress	const SmartIPAddress&		IP address of the runtime system
	inDeviceID	Optional<int>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	outImage	Image&		Captured frame
	outIsRemote	bool&		Specifies whether the program is currently executed on the runtime (True) or development (False) system

Hints

- Check the IP address of your runtime system (e.g. using the "ipconfig" command) and set it to the **inIpAddress** input.
- Run the program on you runtime system and the camera filter will acquire images directly on it.
- Run the program on your development machine (e.g. your laptop) connected to the same Ethernet and the camera filter will receive images through a connection with the runtime system.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_GrabImage_WebCamera is not supported in the Lite edition.

Smart_SetDigitalOutputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets digital outputs using AvSMART interface.

Syntax

```
void avl::Smart_SetDigitalOutputs
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 bool inVal1,
 bool inVal2,
 bool inVal3,
 bool inVal4,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
	ioState	Smart_State&		Object used to maintain state of the function.
	inIpAddress	const SmartIPAddress&		
	inVal1	bool		
	inVal2	bool		
	inVal3	bool		
	inVal4	bool		
	outIsRemote	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_SetDigitalOutputs is not supported in the Lite edition.

Smart_SetDigitalOutputs_GenICam

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set digital outputs.

Syntax

```
void avl::Smart_SetDigitalOutputs_GenICam
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 atl::Optional<const avl::GenAddress&> inDeviceID,
 bool inVal1,
 bool inVal2,
 bool inVal3,
 bool inVal4,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Smart_State&		Object used to maintain state of the function.
→	inIpAddress	const SmartIPAddress&		
→	inDeviceID	Optional<const GenAddress&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
→	inVal1	bool		
→	inVal2	bool		
→	inVal3	bool		
→	inVal4	bool		
←	outIsRemote	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_SetDigitalOutputs_GenICam is not supported in the Lite edition.

Smart_SetDigitalOutputs_Roseek

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set digital outputs.

Syntax

```
void avl::Smart_SetDigitalOutputs_Roseek
(
 Smart_State& ioState,
 const avl::SmartIPAddress& inIpAddress,
 bool inVal1,
 bool inVal2,
 bool inVal3,
 bool inVal4,
 bool& outIsRemote
)
```

Parameters

	Name	Type	Default	Description
	ioState	Smart_State&		Object used to maintain state of the function.
	inIpAddress	const SmartIPAddress&		
	inVal1	bool		
	inVal2	bool		
	inVal3	bool		
	inVal4	bool		
	outIsRemote	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Smart_SetDigitalOutputs_Roseek is not supported in the Lite edition.

- Spinnaker_StopAcquisition

Spinnaker_BayerToRgb

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Convert image to RGB format.

Syntax

```
void avl::Spinnaker_BayerToRgb
(
 Spinnaker_State& ioState,
 const avl::Image& inImage,
 avl::SpinnakerBayerConverter::Type inBayerConverter,
 avl::BayerType::Type inBayerType,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inImage	const Image&		Input image
	inBayerConverter	SpinnakerBayerConverter::Type		
	inBayerType	BayerType::Type		
	outImage	Image&		Output image

Also in AVL Lite

Spinnaker_ExecuteCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes command in GenICam device.

Syntax

```
void avl::Spinnaker_ExecuteCommand
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inCommandName,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inCommandName	const String&		Name of command node to access
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool from Spinnaker device.

Syntax

```
void avl::Spinnaker_GetBoolParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inVerify,
 bool inIgnoreCache,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of parameter node to access
	inVerify	bool		Enables Range verification
	inIgnoreCache	bool		If true the value is read ignoring any caches
	outValue	bool&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enumeration from Spinnaker device.

Syntax

```
void avl::Spinnaker_GetEnumParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inVerify,
 bool inIgnoreCache,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Spinnaker_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of parameter node to access
→	inVerify	bool		Enables Range verification
→	inIgnoreCache	bool		If true the value is read ignoring any caches
←	outValue	String&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer from Spinnaker device.

Syntax

```
void avl::Spinnaker_GetIntegerParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inVerify,
 bool inIgnoreCache,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Spinnaker_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of parameter node to access
→	inVerify	bool		Enables Range verification
→	inIgnoreCache	bool		If true the value is read ignoring any caches
←	outValue	int&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetLineStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads line status.

Syntax

```
void avl::Spinnaker_GetLineStatus
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineSelector,
 bool inVerify,
 bool inIgnoreCache,
 bool& outStatus
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Spinnaker_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying address
	inLineSelector	int	0 - 3		Selects which bit of the User Output register is set by UserOutputValue.
	inVerify	bool		True	Enables Range verification
	inIgnoreCache	bool			If true the value is read ignoring any caches
	outStatus	bool&			Returns the current status of the selected input or output Line

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetRealParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Real from Spinnaker device.

Syntax

```
void avl::Spinnaker_GetRealParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inVerify,
 bool inIgnoreCache,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of parameter node to access
	inVerify	bool		Enables Range verification
	inIgnoreCache	bool		If true the value is read ignoring any caches
	outValue	float&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String from Spinnaker device.

Syntax

```
void avl::Spinnaker_GetStringParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inVerify,
 bool inIgnoreCache,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of parameter node to access
	inVerify	bool		Enables Range verification
	inIgnoreCache	bool		If true the value is read ignoring any caches
	outValue	String&		Value retrieved from device parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Flir camera using Spinnaker interface.

Syntax

```
bool avl::Spinnaker_GrabImage
(
 Spinnaker_State& ioState,
 const atl::Optional<atl::String>& inDeviceSerialNumber,
 atl::Optional<int> inBufferCount,
 atl::Optional<avl::SpinnakerPixelFormat::Type> inPixelFormat,
 avl::SpinnakerBayerConverter::Type inBayerConverter,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inFrameRateEnable,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inGainAuto,
 atl::Optional<double> inGain,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Spinnaker_State&			Object used to maintain state of the function.
→	inDeviceSerialNumber	const Optional<String>&		NIL	Source device serial number
→	inBufferCount	Optional<int>	1 – ∞	10	Number of image buffers
→	inPixelFormat	Optional<SpinnakerPixelFormat::Type>		NIL	Image pixel format
→	inBayerConverter	SpinnakerBayerConverter::Type			Image bayer converter. Used only with Bayer pixel format
→	inExposureAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic exposure mode
→	inExposureTime	Optional<double>	6.0D – ∞	NIL	Exposure time in microseconds
→	inFrameRateEnable	Optional<bool>		NIL	If enabled, inFrameRate can be used to manually control the frame rate
→	inFrameRate	Optional<double>	1.0D – ∞	NIL	Frame rate in Hertz
→	inGainAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic gain mode
→	inGain	Optional<double>	0.0D – ∞	NIL	Controls the amplification of the video signal in dB
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Captured frame ID
←	outTimestamp	int64&			Captured frame timestamp

Description

This filter is intended for establishing connection with camera device using Spinnaker SDK, for streaming images out of it in continuous mode.

Waiting time for new, valid image frame is not limited. For explicitly limiting timeout value and handling timeout condition, use Spinnaker_GrabImage_WithTimeout filter.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Spinnaker SDK. To be able to connect to camera it is required to install Spinnaker SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Spinnaker version v4.3.0.189**.

Spinnaker SDK can be downloaded from the following website: https://www.teledynevisionsolutions.com/support/support-center/software-firmware-downloads (registration may be required).

During installation you should select "Application Development". Visual Studio Version should be also changed to "Visual Studio 2015".

Camera identification

When there is only one camera connected to computer, **inDeviceSerialNumber** field can be set to Auto. In this situation first available camera will be found and connected.

inDeviceSerialNumber can be used to pick one of multiple cameras connected to computer. Set this field to device serial number (for example "1234567", should be available on device casing as "s/n: 1234567").

Camera parameters

Most of parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameters for default configuration by camera driver.

To change other and more advanced camera parameters use configuration tool "SpinView" available with Spinnaker SDK. Refer to SDK documentation to find information about parameters and how to save parameters into memory channels.

It is also possible to adjust more advanced parameters using Spinnaker_SetParameter filters. The parameters name should be obtained from SpinView application or from Spinnaker SDK.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Spinnaker_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures images from a Flir camera using Spinnaker interface; returns Nil if no frame comes in the specified time.

Syntax

```
bool avl::Spinnaker_GrabImage_WithTimeout
(
 Spinnaker_State& ioState,
 const atl::Optional<atl::String>& inDeviceSerialNumber,
 int inTimeout,
 atl::Optional<int> inBufferCount,
 atl::Optional<avl::SpinnakerPixelFormat::Type> inPixelFormat,
 avl::SpinnakerBayerConverter::Type inBayerConverter,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inFrameRateEnable,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<atl::int64>& outFrameID,
 atl::Conditional<atl::int64>& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Spinnaker_State&			Object used to maintain state of the function.
	inDeviceSerialNumber	const Optional<String>&		NIL	Source device serial number
	inTimeout	int	10 – ∞	100	Maximum time to wait for frame in milliseconds
	inBufferCount	Optional<int>	1 – ∞	10	Number of image buffers
	inPixelFormat	Optional<SpinnakerPixelFormat::Type>		NIL	Image pixel format
	inBayerConverter	SpinnakerBayerConverter::Type			Image bayer converter. Used only with Bayer pixel format
	inExposureAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic exposure mode
	inExposureTime	Optional<double>	6.0D – ∞	NIL	Exposure time in microseconds
	inFrameRateEnable	Optional<bool>		NIL	If enabled, inFrameRate can be used to manually control the frame rate
	inFrameRate	Optional<double>	1.0D – ∞	NIL	Frame rate in Hertz
	inGainAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic gain mode
	inGain	Optional<double>	0.0D – ∞	NIL	Controls the amplification of the video signal in dB
	outImage	Conditional<Image>&			Captured frame
	outFrameID	Conditional<int64>&			Captured frame ID
	outTimestamp	Conditional<int64>&			Captured frame timestamp

Description

This filter is intended for establishing connection with general camera device using Spinnaker SDK, for streaming images out of it in continuous mode.

This filter will wait for next valid frame not more that selected timeout value (on **inTimeout** port) in milliseconds. After timeout occurs a Nil value is returned on **outImage** port instead of image.

Similarly to **outImage**, outputs **outFrameID** and **outTimestamp** will return Nil on timeout condition.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Spinnaker SDK. To be able to connect to camera it is required to install Spinnaker SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Spinnaker version v4.3.0.189**.

Spinnaker_SetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Bool.

Syntax

```
void avl::Spinnaker_SetBoolParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	bool		New value to be set into device parameter
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Spinnaker_SetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Enum.

Syntax

```
void avl::Spinnaker_SetEnumParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_SetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Integer.

Syntax

```
void avl::Spinnaker_SetIntegerParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	int		New value to be set into device parameter
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

Spinnaker_SetRealParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Real.

Syntax

```
void avl::Spinnaker_SetRealParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	float		New value to be set into device parameter
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type String.

Syntax

```
void avl::Spinnaker_SetStringParameter
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter
	inVerify	bool	True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_SetUserOutput

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets user output value.

Syntax

```
void avl::Spinnaker_SetUserOutput
(
 Spinnaker_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inUserOutputSelector,
 bool inValue,
 bool inVerify
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Spinnaker_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying address
	inUserOutputSelector	int	0 - 3		Selects which bit of the User Output register is set by UserOutputValue.
	inValue	bool			Value of the selected user output, either logic high (enabled) or logic low (disabled).
	inVerify	bool		True	Enables AccessMode and Range verification (default = true)

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Spinnaker_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts image acquisition.

Syntax

```
void avl::Spinnaker_StartAcquisition
(
 Spinnaker_State& ioState,
 const atl::Optional<atl::String>& inDeviceSerialNumber,
 atl::Optional<int> inBufferCount,
 atl::Optional<avl::SpinnakerPixelFormat::Type> inPixelFormat,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inFrameRateEnable,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::SpinnakerAutoSettings::Type> inGainAuto,
 atl::Optional<double> inGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Spinnaker_State&			Object used to maintain state of the function.
	inDeviceSerialNumber	const Optional<String>&		NIL	Source device serial number
	inBufferCount	Optional<int>	1 – ∞	10	Number of image buffers
	inPixelFormat	Optional<SpinnakerPixelFormat::Type>		NIL	Image pixel format
	inExposureAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic exposure mode
	inExposureTime	Optional<double>	6.0D – ∞	NIL	Exposure time in microseconds
	inFrameRateEnable	Optional<bool>		NIL	If enabled, inFrameRate can be used to manually control the frame rate
	inFrameRate	Optional<double>	1.0D – ∞	NIL	Frame rate in Hertz
	inGainAuto	Optional<SpinnakerAutoSettings::Type>		NIL	Sets the automatic gain mode
	inGain	Optional<double>	0.0D – ∞	NIL	Controls the amplification of the video signal in dB

Description

This filter is intended for establishing connection with a device using Spinnaker SDK, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of Spinnaker_GrabImage or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. Spinnaker_GrabImage or Spinnaker_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke. When this filter is used, the **inPixelFormat** parameter of subsequent Spinnaker_GrabImage and Spinnaker_GrabImage_WithTimeout filters has no effect.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Spinnaker SDK. To be able to connect to camera it is required to install Spinnaker SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Spinnaker version v4.3.0.189**.

Spinnaker SDK can be downloaded from the following website: https://www.teledynevisionsolutions.com/support/support-center/software-firmware-downloads (registration may be required).

During installation you should select "Application Development". Visual Studio Version should be also changed to "Visual Studio 2015".

Camera identification

When there is only one camera connected to computer, **inDeviceSerialNumber** field can be set to Auto. In this situation first available camera will be found and connected.

inDeviceSerialNumber can be used to pick one of multiple cameras connected to computer. Set this field to device serial number (for example "1234567", should be available on device casing as "s/n: 1234567").

Camera parameters

Most of parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameters for default configuration by camera driver.

To change other and more advanced camera parameters use configuration tool "SpinView" available with Spinnaker SDK. Refer to SDK documentation to find information about parameters and how to save parameters into memory channels.

It is also possible to adjust more advanced parameters using Spinnaker_SetParameter filters. The parameters name should be obtained from SpinView application or from Spinnaker SDK.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- Spinnaker_StopAcquisition – Stops image acquisition.

Also in AVL Lite

Spinnaker_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition.

Syntax

```
void avl::Spinnaker_StopAcquisition
(
 Spinnaker_State& ioState,
 const atl::Optional<atl::String>& inDeviceSerialNumber
)
```

Parameters

	Name	Type	Default	Description
	ioState	Spinnaker_State&		Object used to maintain state of the function.
	inDeviceSerialNumber	const Optional<String>&	NIL	Source device serial number

Description

This filter is intended for stopping acquisition in a Flir camera device using Spinnaker SDK. It is only needed when implementing explicit stopping and starting of the image acquisition during a program lifetime.

This filter will usually be executed when image acquisition in a camera is already active (after filters like Spinnaker_GrabImage or Spinnaker_StartAcquisition has been executed). After its execution the image acquisition in a camera and on the application level will be stopped and all image data remaining in the input queue will be discarded. Image acquisition can be reestablished later by executing the Spinnaker_GrabImage, Spinnaker_GrabImage_WithTimeout or Spinnaker_StartAcquisition filters (pixel format and image input queue size parameters will be configured again by those filters).

This filter has no effect when invoked while the camera is not in the image acquisition state.

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Spinnaker SDK. To be able to connect to camera it is required to install Spinnaker SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Spinnaker version v4.3.0.189**.

STC_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger.

Syntax

```
void avl::STC_GenerateSoftwareTrigger
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

Also in AVL Lite

STC_GetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Bool.

Syntax

```
void avl::STC_GetBoolParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter

STC_GetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Double.

Syntax

```
void avl::STC_GetDoubleParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 double& outValue,
 double& outMinValue,
 double& outMaxValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	double&		Value retrieved from device
	outMinValue	double&		Minimum value of the parameter
	outMaxValue	double&		Maximum value of the parameter

STC_GetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Enum.

Syntax

```
void avl::STC_GetEnumParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::String& outValue,
 atl::Array<atl::String>& outValuesList
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	String&		Value retrieved from device
	outValuesList	Array<String>&		List of possible values of the parameter

Also in AVL Lite

STC_GetIntParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Integer.

Syntax

```
void avl::STC_GetIntParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::int64& outValue,
 atl::int64& outMinValue,
 atl::int64& outMaxValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	int64&		Value retrieved from device
	outMinValue	int64&		Minimum value of the parameter
	outMaxValue	int64&		Maximum value of the parameter

Also in AVL Lite

STC_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type String.

Syntax

```
void avl::STC_GetStringParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	outValue	String&		Value retrieved from device

Also in AVL Lite

STC_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using an Omron device.

Syntax

```
bool avl::STC_GrabImage
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<avl::OmronPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<avl::OmronAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<bool> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<double> inGamma,
 atl::Optional<double> inBlackLevel,
 atl::Optional<bool> inTriggerEnable,
 atl::Optional<avl::OmronTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::OmronTriggerActivation::Type> inTriggerActivation,
 atl::Optional<double> inTriggerDelay,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Omron_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inPixelFormat	Optional<OmronPixelFormat::Type>		NIL	Format of the pixels provided by the device
	inRoi	Optional<const Box&>		NIL	Region of interest
	inAcquisitionMode	Optional<OmronAcquisitionMode::Type>		NIL	Acquisition mode of the device
	inAcquisitionFrameCount	Optional<int>		NIL	Number of frames to acquire in MultiFrame Acquisition mode
	inFrameRate	Optional<double>		NIL	Acquisition rate in Hertz at which the frames are captured
	inExposureAuto	Optional<bool>		NIL	Enables or disables the automatic exposure time control
	inExposureTime	Optional<double>		NIL	Exposure time in microseconds
	inGainAuto	Optional<bool>		NIL	Enables or disables the automatic gain control
	inGain	Optional<double>		NIL	Gain as an absolute physical value
	inGamma	Optional<double>		NIL	Gamma correction of pixel intensity
	inBlackLevel	Optional<double>		NIL	Black level as an absolute physical value
	inTriggerEnable	Optional<bool>		NIL	Controls if the selected trigger is active
	inTriggerSource	Optional<OmronTriggerSource::Type>		NIL	Source of the acquisition trigger
	inTriggerActivation	Optional<OmronTriggerActivation::Type>		NIL	Activation mode of the trigger
	inTriggerDelay	Optional<double>		NIL	Delay in microseconds to apply after the trigger reception before activating it
	outImage	Image&			Captured frame
	outFrameID	int64&			Captured frame ID
	outTimestamp	int64&			Captured frame timestamp

Remarks

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Sentech SDK Package software with camera dedicated drivers.

Sentech SDK Package can be downloaded from the following website:
https://sentech.co.jp/en/data/software/ (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Sentech SDK Package version for Aurora Vision Studio usage is **1.1.2 Update 3**.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial Number** – should be printed on the device housing.
- **Device ID** – unique device identifier that can be viewed in StViewer utility.
- **Device User ID** – user-programmable device identifier that can be set in StViewer utility.

Camera parameters

All parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

STC_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using an Omron device.

Syntax

```
bool avl::STC_GrabImage_WithTimeout
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 int inInputQueueSize,
 atl::Optional<avl::OmronPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<avl::OmronAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<bool> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<double> inGamma,
 atl::Optional<double> inBlackLevel,
 atl::Optional<bool> inTriggerEnable,
 atl::Optional<avl::OmronTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::OmronTriggerActivation::Type> inTriggerActivation,
 atl::Optional<double> inTriggerDelay,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<atl::int64>& outFrameID,
 atl::Conditional<atl::int64>& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Omron_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inTimeout	int	1 – ∞	100	Maximum time to wait for frame in milliseconds
→	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
→	inPixelFormat	Optional<OmronPixelFormat::Type>		NIL	Format of the pixels provided by the device
→	inRoi	Optional<const Box&>		NIL	Region of interest
→	inAcquisitionMode	Optional<OmronAcquisitionMode::Type>		NIL	Acquisition mode of the device
→	inAcquisitionFrameCount	Optional<int>		NIL	Number of frames to acquire in MultiFrame Acquisition mode
→	inFrameRate	Optional<double>		NIL	Acquisition rate in Hertz at which the frames are captured
→	inExposureAuto	Optional<bool>		NIL	Enables or disables the automatic exposure time control
→	inExposureTime	Optional<double>		NIL	Exposure time in microseconds
→	inGainAuto	Optional<bool>		NIL	Enables or disables the automatic gain control
→	inGain	Optional<double>		NIL	Gain as an absolute physical value
→	inGamma	Optional<double>		NIL	Gamma correction of pixel intensity
→	inBlackLevel	Optional<double>		NIL	Black level as an absolute physical value
→	inTriggerEnable	Optional<bool>		NIL	Controls if the selected trigger is active
→	inTriggerSource	Optional<OmronTriggerSource::Type>		NIL	Source of the acquisition trigger
→	inTriggerActivation	Optional<OmronTriggerActivation::Type>		NIL	Activation mode of the trigger
→	inTriggerDelay	Optional<double>		NIL	Delay in microseconds to apply after the trigger reception before activating it
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int64>&			Captured frame ID
←	outTimestamp	Conditional<int64>&			Captured frame timestamp

STC_SetBoolParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Bool.

Syntax

```
void avl::STC_SetBoolParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	bool		Value to set

Also in AVL Lite

STC_SetDoubleParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Double.

Syntax

```
void avl::STC_SetDoubleParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	double		Value to set

Also in AVL Lite

STC_SetEnumParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Enum.

Syntax

```
void avl::STC_SetEnumParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	const String&		Value to set

Also in AVL Lite

STC_SetIntParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Integer.

Syntax

```
void avl::STC_SetIntParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	int64		Value to sets

Also in AVL Lite

STC_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type String.

Syntax

```
void avl::STC_SetStringParameter
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameter,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inParameter	const String&		Name of parameter
	inValue	const String&		Value to set

Also in AVL Lite

STC_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in device.

Syntax

```
void avl::STC_StartAcquisition
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<avl::OmronPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inRoi,
 atl::Optional<avl::OmronAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<bool> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<bool> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<double> inGamma,
 atl::Optional<double> inBlackLevel,
 atl::Optional<bool> inTriggerEnable,
 atl::Optional<avl::OmronTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::OmronTriggerActivation::Type> inTriggerActivation,
 atl::Optional<double> inTriggerDelay
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Omron_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inInputQueueSize	int	1 - 200	4	Capacity of output frames queue
	inPixelFormat	Optional<OmronPixelFormat::Type>		NIL	Format of the pixels provided by the device
	inRoi	Optional<const Box&>		NIL	Region of interest
	inAcquisitionMode	Optional<OmronAcquisitionMode::Type>		NIL	Acquisition mode of the device
	inAcquisitionFrameCount	Optional<int>		NIL	Number of frames to acquire in MultiFrame Acquisition mode
	inFrameRate	Optional<double>		NIL	Acquisition rate in Hertz at which the frames are captured
	inExposureAuto	Optional<bool>		NIL	Enables or disables the automatic exposure time control
	inExposureTime	Optional<double>		NIL	Exposure time in microseconds
	inGainAuto	Optional<bool>		NIL	Enables or disables the automatic gain control
	inGain	Optional<double>		NIL	Gain as an absolute physical value
	inGamma	Optional<double>		NIL	Gamma correction of pixel intensity
	inBlackLevel	Optional<double>		NIL	Black level as an absolute physical value
	inTriggerEnable	Optional<bool>		NIL	Controls if the selected trigger is active
	inTriggerSource	Optional<OmronTriggerSource::Type>		NIL	Source of the acquisition trigger
	inTriggerActivation	Optional<OmronTriggerActivation::Type>		NIL	Activation mode of the trigger
	inTriggerDelay	Optional<double>		NIL	Delay in microseconds to apply after the trigger reception before activating it

Remarks

This filter is intended for establishing connection with an Omron camera device using Sentech SDK Package interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program. For example, it can be used to prepare a camera, running in triggered mode, to be able to capture trigger signals before the first invoke of STC_GrabImage or to start multiple cameras in sync before the acquisition phase.

The use of this filter is not obligatory. STC_GrabImage or STC_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

Camera driver software

This filter is intended to cooperate with a camera using its vendor SDK. To be able to connect to a camera, it is required to install Sentech SDK Package software with camera dedicated drivers.

Sentech SDK Package can be downloaded from the following website:
https://sentech.co.jp/en/data/software/ (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Sentech SDK Package version for Aurora Vision Studio usage is **1.1.2 Update 3**.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to computer. DeviceID can be set to:

- **Serial Number** – should be printed on the device housing.
- **Device ID** – unique device identifier that can be viewed in StViewer utility.
- **Device User ID** – user-programmable device identifier that can be set in StViewer utility.

Camera parameters

All parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

To change other, more advanced camera parameters, use specific filters.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

STC_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in device.

Syntax

```
void avl::STC_StopAcquisition
(
 Omron_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Omron_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

SynView_ConfigureDigitalIO

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures SynView digital IO.

Syntax

```
void avl::SynView_ConfigureDigitalIO
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineNumber,
 atl::Optional<bool> inLineInverter,
 atl::Optional<float> inLineDebounceDuration,
 atl::Optional<avl::SynViewLineSource::Type> inLineSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SynView_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inLineNumber	int	1 – 32		I/O line for configuration
	inLineInverter	Optional<bool>		NIL	Invert the signal on the selected line
	inLineDebounceDuration	Optional<float>		NIL	Input line debounce duration in us (0 for disable debouncer)
	inLineSource	Optional<SynViewLineSource::Type>		NIL	Selects a device internal signal that should drive the output signal of the selected line.

Description

The output can be driven by toggling the value of the corresponding user output. To configure UserOutputValue use SynView_SetUserOutput filter.

To connect user output with digital output select **userOutputX** in parameter **inLineSource**.

Advanced output configuration

The output can be driven by a timer, started by an event (e.g. activation UserOutput, Frame Trigger). To active DigitalOutput by timer you need to set **inLineSource** to **TimerXActive**. See also: SynView_ConfigureTimer, SynView Manual: Section 6.7.6 "Advanced output configuration".

Parameters **inLineInverter** and **inLineSource** can be set only for digital outputs.

Parameter **inLineDebounceDuration** can be set only for digital inputs.

The line mapping is fixed for all camera families – all PicSight and CheckSight models. It's briefly summarized in the following table:

I/O lines	Mapped signals
Line1 – Line4	Optocoupler inputs
Line5 – Line8	Reserved
Line9 – Line12	Optocoupler outputs
Line13 – Line16	Reserved
Line17 – Line18	TTL inputs
Line19 – Line24	Reserved
Line25 – Line26	TTL outputs
Line27 – Line32	Reserved

Remarks

For convenience, this filter may be invoked in the main program loop, without significant impact on the performance.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

SynView_ConfigureStrobe

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Controls the built-in camera strobe.

Syntax

```
void avl::SynView_ConfigureStrobe
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewStrobeEnable::Type inStrobeEnabled,
 float inStrobeDuration,
 float inStrobeDelay
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SynView_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inStrobeEnabled	SynViewStrobeEnable::Type			Selects the LED clusters of the strobe light that should be enabled
	inStrobeDuration	float	0.0 – ∞		Duration of the strobe pulse in usec.
	inStrobeDelay	float	0.0 – ∞		A delay before the strobe pulse starts after frame trigger is applied in usec

Remarks

For convenience, this filter may be invoked in the main program loop, without significant impact on the performance.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

SynView_ConfigureTimer

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures one of the internal hardware timers available in the camera.

Syntax

```
void avl::SynView_ConfigureTimer
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewTimerSelector::Type inTimerSelector,
 int inTimerDuration,
 int inTimerDelay,
 avl::SynViewTimerTriggerSource::Type inTimerTriggerSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SynView_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inTimerSelector	SynViewTimerSelector::Type			Timer selector
	inTimerDuration	int	0 – ∞		Sets the duration (in microseconds) of the timer active pulse.
	inTimerDelay	int	0 – ∞		Sets the delay (in microseconds) applied between activating the timer and issuing the timer active signal
	inTimerTriggerSource	SynViewTimerTriggerSource::Type			Internal device signal activating the selected timer.

Description

Advanced digital outputs configuration

The timer has a configurable *Timer Delay* and *Timer Duration* parameters (both in us).

Timers can be used to control digital outputs. In such case, the Line Source in SynView_ConfigureDigitalIO has to be set to e.g. Timer1Active (when **inTimerSelector** is Timer1).

The delay defines, how long after the timer's start the camera asserts the output.

The duration defines, how long the output stays active.

Remarks

The number of timers available depends on the camera model. Timer1 can be assumed to be present.

For convenience, this filter may be invoked in the main program loop, without significant impact on the performance.

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- SynView_ConfigureDigitalIO – Configures SynView digital IO.
- SynView_ConfigureTimer – Configures one of the internal hardware timers available in the camera.
- SynView_GetDigitalIOStates – Gets SynView digital IO states.
- SynView_GrabImage – Captures a frame using SynView.

SynView_ExecuteCommand

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes a command.

Syntax

```
void avl::SynView_ExecuteCommand
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter

SynView_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger, trigger source should be set to 'software'.

Syntax

```
void avl::SynView_GenerateSoftwareTrigger
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	SynView_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)

SynView_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool.

Syntax

```
void avl::SynView_GetBoolParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	SynView_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
→	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
→	inParameterName	const String&		Name of feature parameter
←	outValue	bool&		Value retrieved from device parameter

SynView_GetDigitalIOStates

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets SynView digital IO states.

Syntax

```
void avl::SynView_GetDigitalIOStates
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineNumber,
 bool& outState
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SynView_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
→	inLineNumber	int	1 – 32		I/O line for querying
←	outState	bool&			Current status of the selected line

Description

This filter gets the logical state of the selected Digital IO line.

The line mapping is fixed for all camera families – all PicSight and CheckSight models. It's briefly summarized in the following table, details are listed in SynView Manual Sections: "Input and output signals" and "Connector and cable description".

I/O lines	Mapped signals
Line1 – Line4	Optocoupler inputs
Line5 – Line8	Reserved
Line9 – Line12	Optocoupler outputs
Line13 – Line16	Reserved
Line17 – Line18	TTL inputs
Line19 – Line24	Reserved
Line25 – Line26	TTL outputs
Line27 – Line32	Reserved

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

SynView_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enumeration.

Syntax

```
void avl::SynView_GetEnumParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	outValue	String&		Value retrieved from device parameter

SynView_GetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::SynView_GetIntegerParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	outValue	int&		Value retrieved from device parameter

SynView_GetLongParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Long.

Syntax

```
void avl::SynView_GetLongParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	outValue	int64&		Value retrieved from device parameter

SynView_GetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Real.

Syntax

```
void avl::SynView_GetRealParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	outValue	float&		Value retrieved from device parameter

SynView_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::SynView_GetStringParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	outValue	String&		Value retrieved from device parameter

Also in AVL Lite

SynView_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using SynView.

Syntax

```
bool avl::SynView_GrabImage
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::SynViewColorFormat::Type inColorFormat,
 const avl::SynViewAcquisitionParams& inAcquisitionParams,
 const avl::SynViewImageFormatParams& inImageFormatParams,
 const avl::SynViewAnalogParams& inAnalogParams,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	SynView_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
→	inInputQueueSize	int	1 – ∞	4	Capacity of input frames queue
→	inColorFormat	SynViewColorFormat::Type			Image color format
→	inAcquisitionParams	const SynViewAcquisitionParams&			
→	inImageFormatParams	const SynViewImageFormatParams&			
→	inAnalogParams	const SynViewAnalogParams&			
←	outImage	Image&			Captured frame
←	outFrameID	int64&			Output frame number; 0 if not supported
←	outTimestamp	int64&			Output image timestamp; 0 if not supported

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

Camera parameters

All parameters passed to camera filters are optional, setting them to 'Auto' leaves related parameters unchanged in the camera (device default or user set configuration).

To change other and more advanced camera parameters use the configuration tool "SynView Explorer" available with SynView SDK. Refer to the SDK documentation to find information about parameters and how to create default startup configuration.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- SynView_ConfigureDigitalIO – Configures SynView digital IO.
- SynView_ConfigureTimer – Configures one of the internal hardware timers available in the camera.
- SynView_GetDigitalIOStates – Gets SynView digital IO states.
- SynView_SetUserOutput – Sets SynView user outputs.

SynView_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using SynView; returns Nil if no frame comes in the specified time.

Applications: Use this filter if the trigger may be not coming for some time, while the application should be performing other operations continuously (e.g. processing HMI events).

Syntax

```
bool avl::SynView_GrabImage_WithTimeout
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::SynViewColorFormat::Type inColorFormat,
 int inTimeout,
 const avl::SynViewAcquisitionParams& inAcquisitionParams,
 const avl::SynViewImageFormatParams& inImageFormatParams,
 const avl::SynViewAnalogParams& inAnalogParams,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<atl::int64>& outFrameID,
 atl::Conditional<atl::int64>& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SynView_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inInputQueueSize	int	1 – ∞	4	Capacity of input frames queue
	inColorFormat	SynViewColorFormat::Type			Image color format
	inTimeout	int	100 – 3600000	5000	Maximum time to wait for frame in milliseconds
	inAcquisitionParams	const SynViewAcquisitionParams&			
	inImageFormatParams	const SynViewImageFormatParams&			
	inAnalogParams	const SynViewAnalogParams&			
	outImage	Conditional<Image>&			Captured frame
	outFrameID	Conditional<int64>&			Output frame number; 0 if not supported
	outTimestamp	Conditional<int64>&			Output image timestamp; 0 if not supported

SynView_SetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Bool.

Syntax

```
void avl::SynView_SetBoolParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	inValue	bool		New value to be set into device parameter

SynView_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Enumeration.

Syntax

```
void avl::SynView_SetEnumParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

SynView_SetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Integer.

Syntax

```
void avl::SynView_SetIntegerParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	inValue	int		New value to be set into device parameter

SynView_SetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Real.

Syntax

```
void avl::SynView_SetRealParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	inValue	float		New value to be set into device parameter

SynView_SetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type String.

Syntax

```
void avl::SynView_SetStringParameter
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewFeatureGroup::Type inFeatureGroup,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inFeatureGroup	SynViewFeatureGroup::Type		Parameters feature group
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

SynView_SetUserOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets SynView user outputs.

Syntax

```
void avl::SynView_SetUserOutput
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 avl::SynViewUserOutputs::Type inUserOutput,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inUserOutput	SynViewUserOutputs::Type		User output for configuration
	inValue	bool		Status of the selected user output

Description

Digital IO output lines can be driven by toggling values of the corresponding user outputs - select the User Output Number, then set its bool value.

To connect a user output with a digital output use the SynView_ConfigureDigitalIO filter.

User outputs can be used to enable synView timers for advanced digital outputs control. To configure it use the SynView_ConfigureTimer filter, setting Timer Trigger Source accordingly.

More info about user outputs can be found in the SynView Manual: Section 6.7.5 "User output configuration."

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install SynView SDK software with camera dedicated drivers.

SynView SDK can be downloaded from the following website: https://net-gmbh.com/en/machine-vision/products/software

To verify the driver installation, you can run SynView Explorer (in the directory where camera drivers where installed). If the camera was detected and you can see the view from the camera, you can use SynView camera SDK in Aurora Vision Studio.

Recommended SynView SDK version for Aurora Vision Studio usage is 1.03.014.

Camera identification

When there is only one camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **UserID** – User ID (also known as nickname) of the selected device,
- **VendorName** – Name of the manufacturer of the device,
- **ModelName** – Model name of the device,
- **DisplayName** – Device display name,
- **IPAddress** – Current IP address of the selected device (GigE Vision devices only),
- **MACAddress** – MAC address of the selected device (GigE Vision devices only),
- **SerialNumber** – String representation of camera's unique serial number.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Also in AVL Lite

SynView_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a SynView camera.

Applications: Typically used for establishing camera connectivity before the first trigger event. Especially important for multiple-camera systems.

Syntax

```
void avl::SynView_StartAcquisition
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 avl::SynViewColorFormat::Type inColorFormat,
 const avl::SynViewAcquisitionParams& inAcquisitionParams,
 const avl::SynViewImageFormatParams& inImageFormatParams,
 const avl::SynViewAnalogParams& inAnalogParams
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	SynView_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)
	inInputQueueSize	int	1 – ∞	4	Capacity of input frames queue
	inColorFormat	SynViewColorFormat::Type			Image color format
	inAcquisitionParams	const SynViewAcquisitionParams&			
	inImageFormatParams	const SynViewImageFormatParams&			
	inAnalogParams	const SynViewAnalogParams&			

Also in AVL Lite

SynView_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition.

Syntax

```
void avl::SynView_StopAcquisition
(
 SynView_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	SynView_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Tries to find the camera in all available IDs (UserID, VendorName, ModelName...)

Thorlabs_ConfigureCamera

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets various camera's parameters before starting acquisition.

Syntax

```
void avl::Thorlabs_ConfigureCamera
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<const avl::Box&> inRoi,
 int inXBin,
 int inYBin,
 avl::ThorlabsReadoutSpeed::Type inReadoutSpeed,
 avl::ThorlabsTaps::Type inTaps,
 bool inTapBalance
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Thorlabs_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number or name, Auto = first camera
	inRoi	Optional<const Box&>		NIL	Region of interest, Auto = full frame
	inXBin	int	1 – ∞	1	Horizontal binning factor
	inYBin	int	1 – ∞	1	Vertical binning factor
	inReadoutSpeed	ThorlabsReadoutSpeed::Type			Speed of camera's sensor readout clock
	inTaps	ThorlabsTaps::Type			Number of taps (simultaneous camera sensor readout operations per clock cycle)
	inTapBalance	bool			Whether internal tap balancing is enabled

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_ConfigureTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets triggering parameters.

Syntax

```
void avl::Thorlabs_ConfigureTrigger
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 bool inTriggerEnabled,
 avl::ThorlabsTriggerPolarity::Type inTriggerPolarity,
 atl::Optional<int> inFrameCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Thorlabs_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number or name, Auto = first camera
	inTriggerEnabled	bool		False	True if using trigger
	inTriggerPolarity	ThorlabsTriggerPolarity::Type			Polarity of trigger input
	inFrameCount	Optional<int>	1 – ∞	NIL	Number of frames to capture after trigger, Auto = continuous acquisition

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Thorlabs SDK. To be able to connect to camera it is required to install Thorlabs SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Thorlabs SDK version 2.9.1**.

Thorlabs SDK can be downloaded from the following website:
https://www.thorlabs.com/software_pages/ViewSoftwarePage.cfm?Code=ThorCam

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Bool.

Syntax

```
void avl::Thorlabs_GetBoolParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Thorlabs_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	bool&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Enum.

Syntax

```
void avl::Thorlabs_GetEnumParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Thorlabs_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	String&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer.

Syntax

```
void avl::Thorlabs_GetIntegerParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Thorlabs_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	int&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Real.

Syntax

```
void avl::Thorlabs_GetRealParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Thorlabs_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
→	inParameterName	const String&		Name of parameter
←	outParameterValue	float&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type String.

Syntax

```
void avl::Thorlabs_GetStringParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	outParameterValue	String&		Value of parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a Thorlabs device.

Syntax

```
bool avl::Thorlabs_GrabImage
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<int> inInputQueueSize,
 atl::Optional<int> inExposureTime,
 atl::Optional<int> inGain,
 avl::Image& outImage,
 int& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Thorlabs_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number or name, Auto = first camera
	inInputQueueSize	Optional<int>	0 – ∞	NIL	Sets size of image queue (on acquisition start, default = 8)
	inExposureTime	Optional<int>	1 – ∞	50000	Sets the target exposure time in microseconds
	inGain	Optional<int>	0 – 1023	120	Sets gain
	outImage	Image&			Captured frame
	outFrameID	int&			Captured frame ID

Remarks

Camera driver software

This filter is intended to cooperate with camera using its vendor Thorlabs SDK. To be able to connect to camera it is required to install Thorlabs SDK software with camera dedicated drivers. Currently Aurora Vision Studio uses **Thorlabs SDK version 2.9.1**.

Thorlabs SDK can be downloaded from the following website:
https://www.thorlabs.com/software_pages/ViewSoftwarePage.cfm?Code=ThorCam

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a Thorlabs device.

Syntax

```
bool avl::Thorlabs_GrabImage_WithTimeout
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 atl::Optional<int> inInputQueueSize,
 atl::Optional<int> inExposureTime,
 atl::Optional<int> inGain,
 atl::Conditional<avl::Image>& outImage,
 int& outFrameID
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Thorlabs_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Camera serial number or name, Auto = first camera
→	inTimeout	int			Maximum time to wait for frame in milliseconds
→	inInputQueueSize	Optional<int>	0 – ∞	NIL	Sets size of image queue (on acquisition start, default = 8)
→	inExposureTime	Optional<int>	1 – ∞	50000	Sets the target exposure time in microseconds
→	inGain	Optional<int>	0 – 1023	120	Sets gain
←	outImage	Conditional<Image>&			Captured image
←	outFrameID	int&			Captured frame ID

Thorlabs_SetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Bool.

Syntax

```
void avl::Thorlabs_SetBoolParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	bool		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Enum.

Syntax

```
void avl::Thorlabs_SetEnumParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	const String&		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_SetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Integer.

Syntax

```
void avl::Thorlabs_SetIntegerParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	int		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_SetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Real.

Syntax

```
void avl::Thorlabs_SetRealParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	float		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_SetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type String.

Syntax

```
void avl::Thorlabs_SetStringParameter
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inParameterValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera
	inParameterName	const String&		Name of parameter
	inParameterValue	const String&		Value to set to parameter

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Thorlabs_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a device.

Syntax

```
void avl::Thorlabs_StartAcquisition
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 atl::Optional<int> inInputQueueSize,
 atl::Optional<int> inExposureTime,
 atl::Optional<int> inGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	Thorlabs_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Camera serial number or name, Auto = first camera
	inInputQueueSize	Optional<int>	0 – ∞	NIL	Sets size of image queue (on acquisition start, default = 8)
	inExposureTime	Optional<int>	1 – ∞	50000	Sets the target exposure time in microseconds
	inGain	Optional<int>	0 – 1023	120	Sets gain

Thorlabs_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a device.

Syntax

```
void avl::Thorlabs_StopAcquisition
(
 Thorlabs_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	Thorlabs_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Camera serial number or name, Auto = first camera

Vimba_GetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Bool from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetBoolParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	outValue	bool&		Value retrieved from device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_GetDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a digital input state from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetDigitalInput
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineNumber,
 bool& outState
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Vimba_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inLineNumber	int		Line number to get state
←	outState	bool&		State of selected line

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_GetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Enumeration from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetEnumParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Vimba_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	String&		Value retrieved from device parameter

Remarks

Vimba_GetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Integer from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetIntegerParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Vimba_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	int&		Value retrieved from device parameter

Remarks

Vimba_GetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type Real from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetRealParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Vimba_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	float&		Value retrieved from device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_GetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a parameter of type String from an Allied Vision camera.

Syntax

```
void avl::Vimba_GetStringParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	Vimba_State&		Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>	NIL	Device identifying address
→	inParameterName	const String&		Name of feature parameter
←	outValue	String&		Value retrieved from device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an Allied Vision camera.

Syntax

```
bool avl::Vimba_GrabImage
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const avl::VimbaImageFormatParams& inImageFormat,
 const avl::VimbaAcquisitionControlParams& inAcquisitionControl,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inImageFormat	const VimbaImageFormatParams&		Image format parameters
	inAcquisitionControl	const VimbaAcquisitionControlParams&		Acquisition control parameters
	outImage	Image&		Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_GrabImage_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from an Allied Vision camera; returns Nil if no frame comes in the specified time.

Applications: Use this filter if the trigger may be not coming for some time, while the application should be performing other operations continuously (e.g. processing HMI events).

Syntax

```
bool avl::Vimba_GrabImage_WithTimeout
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 const avl::VimbaImageFormatParams& inImageFormat,
 const avl::VimbaAcquisitionControlParams& inAcquisitionControl,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	Vimba_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying address
→	inTimeout	int	100 – 3600000	5000	Maximum time to wait for frame in milliseconds
→	inImageFormat	const VimbaImageFormatParams&			Image format parameters
→	inAcquisitionControl	const VimbaAcquisitionControlParams&			Acquisition control parameters
←	outImage	Conditional<Image>&			Captured frame

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_SetBoolParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Bool into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetBoolParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	bool		New value to be set into device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a digital output state into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetDigitalOutput
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inLineNumber,
 bool inState
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inLineNumber	int		Line number to change state
	inState	bool		State to set

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

Camera identification

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_SetEnumParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Enumeration into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetEnumParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Also in AVL Lite

Vimba_SetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Integer into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetIntegerParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	int		New value to be set into device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_SetRealParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type Real into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetRealParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	float		New value to be set into device parameter

Remarks

Camera driver software

This filter is intended to cooperate with cameras using their vendor's SDK. In order to connect with the camera, it is required to install Vimba SDK software.

Vimba SDK can be downloaded from the following website:
https://www.alliedvision.com/en/products/software.html

To verify the driver installation, you can run Vimba Viewer. If the camera was detected and you can see the view from the camera, you can use Vimba SDK in Aurora Vision Studio.

Recommended Vimba SDK version for Aurora Vision Studio usage is 6.0.

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_SetStringParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a parameter of type String into an Allied Vision camera.

Syntax

```
void avl::Vimba_SetStringParameter
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inParameterName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inParameterName	const String&		Name of feature parameter
	inValue	const String&		New value to be set into device parameter

Remarks

Camera driver software

When there is only one Allied Vision camera connected, the field **inDeviceID** can be set to Auto. In this situation, the first available camera will be used.

inDeviceID can be used to pick one of multiple cameras connected to the computer. **inDeviceID** should be set to camera ID.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Vimba_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts capturing images from an Allied Vision camera.

Applications: Typically used for establishing camera connectivity before the first trigger event. Especially important for multiple-camera systems.

Syntax

```
void avl::Vimba_StartAcquisition
(
 Vimba_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const avl::VimbaImageFormatParams& inImageFormat,
 const avl::VimbaAcquisitionControlParams& inAcquisitionControl
)
```

Parameters

	Name	Type	Default	Description
	ioState	Vimba_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying address
	inImageFormat	const VimbaImageFormatParams&		Image format parameters
	inAcquisitionControl	const VimbaAcquisitionControlParams&		Acquisition control parameters

Remarks

Camera driver software

VisionBox_ConfigureLedGenerator

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures led signal generator.

Syntax

```
void avl::VisionBox_ConfigureLedGenerator
(
 VisionBox_State& ioState,
 const int inGeneratorIndex,
 const int inBlinkCount,
 const int inMs_ton,
 const int inMs_toff,
 const int inMs_tpause
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inGeneratorIndex	const int	0 – 1		Number of generator to configure
	inBlinkCount	const int	1 – 16		Count of LED blinks
	inMs_ton	const int	100 – 6400		Duration of "ON" signal
	inMs_toff	const int	100 – 6400		Duration of "OFF" signal
	inMs_tpause	const int	0 – 6400		Duration of pause between sequences

Description

This filter is simple wrapper over Led::ConfigureGenerator SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_ConnectMultiplexerOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Connects internal multiplexer signals.

Syntax

```
void avl::VisionBox_ConnectMultiplexerOutput
(
 VisionBox_State& ioState,
 const int inOutputIndex,
 const avl::VisionBoxMuxSource::Type inTriggerSource
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inOutputIndex	const int		
	inTriggerSource	const VisionBoxMuxSource::Type		

Description

This filter is simple wrapper over Multiplexer::ConnectOutput SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetCameraTriggerNumberOfOutputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of outputs of camera trigger device.

Syntax

```
void avl::VisionBox_GetCameraTriggerNumberOfOutputs
(
 VisionBox_State& ioState,
 const int inDeviceNumber,
 int& outNumberOfOutputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inDeviceNumber	const int		
	outNumberOfOutputs	int&		

Description

This filter is simple wrapper over CameraTrigger::GetNumberOfOutputs SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads a digital input state of Imago VisionBox computers.

Syntax

```
void avl::VisionBox_GetDigitalInput
(
 VisionBox_State& ioState,
 const int inPort,
 const int inInput,
 bool& outState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inPort	const int		Number of DigitalInput device to use
	inInput	const int		Number of input to read
	outState	bool&		State of selected input pin

Description

This filter can read state of digital inputs of Imago VisionBox computers. Number of inputs vary between hardware editions.

One should specify **inPort** to access, and **inInput** (singular pin) to read its **outState**. Refer to Hardware Manual to see physical connection of input pins of ones' VisionBox.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- VisionBox_SetDigitalOutput – Sets a digital output state of Imago VisionBox computers.

VisionBox_GetMultiplexerNumberOfOutputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of multiplexer outputs.

Syntax

```
void avl::VisionBox_GetMultiplexerNumberOfOutputs
(
 VisionBox_State& ioState,
 int& outNumberOfOutputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outNumberOfOutputs	int&		

Description

This filter is simple wrapper over Multiplexer::GetNumberOfOutputs SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetNumberOfDigitalInputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of available digital inputs.

Syntax

```
void avl::VisionBox_GetNumberOfDigitalInputs
(
 VisionBox_State& ioState,
 const int inPort,
 int& outNumberOfInputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inPort	const int		Number of DigitalInput device to use
	outNumberOfInputs	int&		Number of Digital Inputs

Description

This filter is simple wrapper over DigitalInput::GetNumberOfInputs SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetNumberOfDigitalOutputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of digital outputs.

Syntax

```
void avl::VisionBox_GetNumberOfDigitalOutputs
(
 VisionBox_State& ioState,
 const int inPort,
 int& outNumberOfOutputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inPort	const int		
	outNumberOfOutputs	int&		

Description

This filter is simple wrapper over DigitalOutput::GetNumberOfOutputs SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetNumberOfLeds

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of available LEDs.

Syntax

```
void avl::VisionBox_GetNumberOfLeds
(
 VisionBox_State& ioState,
 int& outCount
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outCount	int&		Number of LEDs in system

Description

This filter is simple wrapper over Led::GetNumberOfLeds SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_GetTriggerGeneratorConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets trigger generator configuration.

Syntax

```
void avl::VisionBox_GetTriggerGeneratorConfiguration
(
 VisionBox_State& ioState,
 const atl::String& inConfigCommand,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inConfigCommand	const String&		String with value to read
	outValue	int&		Requested value

Description

This filter is simple wrapper over TriggerGenerator::ConfigureGet SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerGetBufferFillLevel

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns number of occupied entries in IO Scheduler buffer.

Syntax

```
void avl::VisionBox_IOSchedulerGetBufferFillLevel
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 int& outBufferFillLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	outBufferFillLevel	int&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

VisionBox_IOSchedulerGetBufferMaxElementCount

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns maximum number of entries in IO Scheduler buffer.

Syntax

```
void avl::VisionBox_IOSchedulerGetBufferMaxElementCount
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 int& outBufferSize
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	outBufferSize	int&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerGetCounter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets values of selected counter in IO Scheduler unit.

Syntax

```
void avl::VisionBox_IOSchedulerGetCounter
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 avl::VisionBoxIOSchedulerCounter::Type inCounterType,
 int& outCounterValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	VisionBox_State&			Object used to maintain state of the function.
→	inSchedulerUnitNumber	const int	0 – ∞		
→	inCounterType	VisionBoxIOSchedulerCounter::Type			
←	outCounterValue	int&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerGetNumberOfOutputs

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns number of available outputs of IO Scheduler unit of Vision Box computer.

Syntax

```
void avl::VisionBox_IOSchedulerGetNumberOfOutputs
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 int& outNumberOfOutputs
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	VisionBox_State&			Object used to maintain state of the function.
→	inSchedulerUnitNumber	const int	0 – ∞		
←	outNumberOfOutputs	int&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerPushValue

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Puts value in IO Scheduler buffer.

Syntax

```
void avl::VisionBox_IOSchedulerPushValue
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 const int inCompareValue,
 const int inOutputValue
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	inCompareValue	const int			
	inOutputValue	const int			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot accept negative value on inCompareValue
DomainError	Cannot accept negative value on inOutputValue

Also in AVL Lite

VisionBox_IOSchedulerReset

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets and disable IO Scheduler logic.

Syntax

```
void avl::VisionBox_IOSchedulerReset()
```

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerSetCompareSource

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures comparison element of IO Scheduler unit.

Syntax

```
void avl::VisionBox_IOSchedulerSetCompareSource
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 avl::VisionBoxIOSchedulerCmpSrc::Type inCompareSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	inCompareSource	VisionBoxIOSchedulerCmpSrc::Type			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

VisionBox_IOSchedulerSetEncoderDirection

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures direction of encoder input of IO Scheduler unit.

Syntax

```
void avl::VisionBox_IOSchedulerSetEncoderDirection
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 avl::VisionBoxIOSchedulerEncoderDir::Type inEncoderDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	inEncoderDirection	VisionBoxIOSchedulerEncoderDir::Type			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_IOSchedulerSetOutputPulsTiming

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configure pulse parameters of IO Scheduler output.

Syntax

```
void avl::VisionBox_IOSchedulerSetOutputPulsTiming
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 const int inDelayInUs,
 const int inTimeInUs
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	inDelayInUs	const int			
	inTimeInUs	const int			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot accept negative time values!

VisionBox_IOSchedulerSetTriggerSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Connects signal to IO Scheduler input.

Syntax

```
void avl::VisionBox_IOSchedulerSetTriggerSource
(
 VisionBox_State& ioState,
 const int inSchedulerUnitNumber,
 const int inInputIndex,
 const bool inInvertInput
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inSchedulerUnitNumber	const int	0 – ∞		
	inInputIndex	const int			
	inInvertInput	const bool			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot accept negative value of inInputIndex

VisionBox_IOSchedulerStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Enables IO Scheduler logic in FPGA unit of Vision Box.

Syntax

```
void avl::VisionBox_IOSchedulerStart()
```

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS232ConfigureBaudRate

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Configures RS232 port. Has to be called before any other Vision Box' RS232 operation.

Syntax

```
void avl::VisionBox_RS232ConfigureBaudRate
(
 VisionBox_State& ioState,
 const int inBaudRate
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	VisionBox_State&			Object used to maintain state of the function.
	inBaudRate	const int	9600 – 921600		

Description

This filter is simple wrapper over Rs232::ConfigureBaudRate SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS232GetAvailableByteCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets number of bytes waiting in RS232 buffer.

Syntax

```
void avl::VisionBox_RS232GetAvailableByteCount
(
 VisionBox_State& ioState,
 int& outBytesAvailable
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outBytesAvailable	int&		

Description

This filter is simple wrapper over Rs232::GetNumberOfBytesAvailable SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS232ReadNBytes

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads byte array from RS232 port.

Syntax

```
void avl::VisionBox_RS232ReadNBytes
(
 VisionBox_State& ioState,
 const int inBytesToRead,
 const int inTimeoutInMs,
 atl::Array<int>& outData,
 int& outBytesReceived
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	VisionBox_State&			Object used to maintain state of the function.
→	inBytesToRead	const int			
→	inTimeoutInMs	const int	0 – ∞		
←	outData	Array<int>&			
←	outBytesReceived	int&			

Description

This filter is simple wrapper over Rs232::ReadNByte SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS232WriteNBytes

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sends byte array through RS232 port.

Syntax

```
void avl::VisionBox_RS232WriteNBytes
(
 VisionBox_State& ioState,
 const atl::Array<int>& inBytesToWrite
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inBytesToWrite	const Array<int>&		

Description

This filter is simple wrapper over Rs232::WriteNByte SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Values of inBytesToWrite array has to be between 0 a 255

VisionBox_RS422Get

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads state of inputs as integer number.

Syntax

```
void avl::VisionBox_RS422Get
(
 VisionBox_State& ioState,
 int& outInputState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outInputState	int&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

VisionBox_RS422GetBit

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads state of particular input of RS 422 port.

Syntax

```
void avl::VisionBox_RS422GetBit
(
 VisionBox_State& ioState,
 const int inBitIndex,
 bool& outBitState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inBitIndex	const int		
	outBitState	bool&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
DomainError	Cannot accept negative bit index

VisionBox_RS422GetNumberOfInputs

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns number of available inputs of RS 422 port.

Syntax

```
void avl::VisionBox_RS422GetNumberOfInputs
(
 VisionBox_State& ioState,
 int& outNumberOfInputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outNumberOfInputs	int&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

VisionBox_RS422GetNumberOfOutputs

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns number of available outputs of RS 422 port.

Syntax

```
void avl::VisionBox_RS422GetNumberOfOutputs
(
 VisionBox_State& ioState,
 int& outNumberOfOutputs
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	outNumberOfOutputs	int&		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS422Set

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets all outputs of RS422 port.

Syntax

```
void avl::VisionBox_RS422Set
(
 VisionBox_State& ioState,
 const int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inValue	const int		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_RS422SetBit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets state of particular output of RS 422 port.

Syntax

```
void avl::VisionBox_RS422SetBit
(
 VisionBox_State& ioState,
 const int inBitIndex,
 const bool inBitState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inBitIndex	const int		
	inBitState	const bool		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Cannot accept negative bit index.

VisionBox_RS422SetSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets source of RS 422 port outputs.

Syntax

```
void avl::VisionBox_RS422SetSource
(
 VisionBox_State& ioState,
 const int inBitIndex,
 const avl::VisionBoxRS422OutSource::Type inSourceType,
 const bool inInvertOutput
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inBitIndex	const int		
	inSourceType	const VisionBoxRS422OutSource::Type		
	inInvertOutput	const bool		

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Errors

List of possible exceptions:

Error type	Description
RuntimeError	Cannot accept negative bit index

VisionBox_SetCameraTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets camera trigger configuration.

Syntax

```
void avl::VisionBox_SetCameraTrigger
(
 VisionBox_State& ioState,
 const int inDeviceNumber,
 const atl::Optional<int> inChannelNumber,
 const avl::VisionBoxTriggerSource::Type inTriggerSource,
 const bool inTrgPOff,
 const bool inTrgPOn,
 const bool inTrgNOff,
 const bool inTrgNOn
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inDeviceNumber	const int		Device number
	inChannelNumber	const Optional<int>	NIL	Channel in device - when set to auto all channels will be configured at the same time
	inTriggerSource	const VisionBoxTriggerSource::Type		Signal used to issue the trigger
	inTrgPOff	const bool		P Gate OFF signal
	inTrgPOn	const bool		P Gate ON signal
	inTrgNOff	const bool		N Gate OFF signal
	inTrgNOn	const bool		N Gate ON signal

Description

This filter is simple wrapper over CameraTrigger::Set SDK function. Refer to AGE-X SDK to see how to use this function properly.

When **inChannelNumber** is set to auto, CameraTrigger::SetAll is used.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_SetDigitalOutput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a digital output state of Imago VisionBox computers.

Syntax

```
void avl::VisionBox_SetDigitalOutput
(
 VisionBox_State& ioState,
 const int inPort,
 const int inOutput,
 const bool inState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inPort	const int		Number of DigitalOutput device to use
	inOutput	const int		Number of output to change
	inState	const bool		State of pin output to set

Description

This filter can set state of digital outputs of Imago VisionBox computers. Number of outputs vary between hardware editions.

One should specify **inPort** to access, and **inOutput** (singular pin) to set given **inState**. Refer to Hardware Manual to see physical connection of output pins of ones' VisionBox.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

See Also

- VisionBox_GetDigitalInput – Reads a digital input state of Imago VisionBox computers.

VisionBox_SetDigitalOutputSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets source for specified digital output pin.

Syntax

```
void avl::VisionBox_SetDigitalOutputSource
(
 VisionBox_State& ioState,
 const int inPort,
 const int inPin,
 avl::VisionBoxDigitalOutSource::Type inSource,
 const bool inInvertOutput
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inPort	const int		
	inPin	const int		
	inSource	VisionBoxDigitalOutSource::Type		
	inInvertOutput	const bool		

Description

This filter is simple wrapper over DigitalOutput::SetSource SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_SetLed

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets led state.

Syntax

```
void avl::VisionBox_SetLed
(
 VisionBox_State& ioState,
 const int inLedIndex,
 const bool inLedState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inLedIndex	const int		Selects led
	inLedState	const bool		Whether to turn led on or off

Description

This filter is simple wrapper over Led::SetLED SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_SetLedMode

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets led mode.

Syntax

```
void avl::VisionBox_SetLedMode
(
 VisionBox_State& ioState,
 const int inLedIndex,
 const avl::VisionBoxLedMode::Type inMode
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inLedIndex	const int		Selects led
	inMode	const VisionBoxLedMode::Type		Selects led mode

Description

This filter is simple wrapper over Led::SetMode SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_SetTriggerGeneratorConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets trigger generator configuration.

Syntax

```
void avl::VisionBox_SetTriggerGeneratorConfiguration
(
 VisionBox_State& ioState,
 const atl::String& inConfigCommand
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inConfigCommand	const String&		String with settings command

Description

This filter is simple wrapper over TriggerGenerator::ConfigureSet SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeInit

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes Strobe. Has to be called before any other Strobe related function.

Syntax

```
void avl::VisionBox_StrobeInit
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const bool inReset
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		
	inReset	const bool	True	

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetCurrent

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes current.

Syntax

```
void avl::VisionBox_StrobeSetCurrent
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const int inCurrent,
 const int inValidate
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inCurrent	const int		Desired current in mA
	inValidate	const int		Whether to validate current

Description

This filter is simple wrapper over Strobe::SetCurrent SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetFixedCurrent

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes fixed current.

Syntax

```
void avl::VisionBox_StrobeSetFixedCurrent
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const int inSupplyVoltage,
 const int inLoadVoltage,
 const int inMaxOnTime,
 const int inMinOffTime,
 const int inCurrent,
 int& outResult
)
```

Parameters

	Name	Type	Default	Description
↔	ioState	VisionBox_State&		Object used to maintain state of the function.
→	inStrobeUnit	const int		Number of strobe device to use
→	inSupplyVoltage	const int		Supply voltage used for the strobe output
→	inLoadVoltage	const int		The voltage across the load when the output current is equal to inCurrent
→	inMaxOnTime	const int		Maximum allowed on-time in us
→	inMinOffTime	const int		Minimum allowed off-time in us
→	inCurrent	const int		Output current in mA
←	outResult	int&		Minimum allowed off-time

Description

This filter is simple wrapper over Strobe::SetFixedCurrent SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetLimits

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes limits.

Syntax

```
void avl::VisionBox_StrobeSetLimits
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const int inLimitCurrent,
 const int inMaxSupplyVoltage,
 const int inMaxLoadVoltage,
 const int inMaxOnTime,
 const int inMinOffTime,
 const int inMaxCurrent,
 int& outResult
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inLimitCurrent	const int		Calculate allowed off-time or maximum current
	inMaxSupplyVoltage	const int		Supply voltage
	inMaxLoadVoltage	const int		Voltage across the load with MaxCurrent current
	inMaxOnTime	const int		Maximum allowed on-time
	inMinOffTime	const int		Minimum allowed off-time
	inMaxCurrent	const int		Maximum allowed current in mA
	outResult	int&		Result calculated regarding inLimitCurrent value

Description

This filter is simple wrapper over Strobe::SetLimits SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetOnTime

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes on-time.

Syntax

```
void avl::VisionBox_StrobeSetOnTime
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const int inOnTime
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inOnTime	const int		On-time in us

Description

This filter is simple wrapper over Strobe::SetOnTime SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetTriggerDelay

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes trigger delay.

Syntax

```
void avl::VisionBox_StrobeSetTriggerDelay
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const int inTriggerDelay
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inTriggerDelay	const int		Delay in us

Description

This filter is simple wrapper over Strobe::SetTriggerDelay SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetTriggerMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes trigger mode.

Syntax

```
void avl::VisionBox_StrobeSetTriggerMode
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const avl::VisionBoxStrobeMode::Type inMode,
 int& outResult
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inMode	const VisionBoxStrobeMode::Type		Selects strobe mode
	outResult	int&		Whether new mode has been selected

Description

This filter is simple wrapper over Strobe::SetTriggerMode SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSetTriggerSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes trigger source.

Syntax

```
void avl::VisionBox_StrobeSetTriggerSource
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const avl::VisionBoxStrobeSource::Type inSource,
 const int inInvertTrigger
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inSource	const VisionBoxStrobeSource::Type		Selects the signal used as trigger source
	inInvertTrigger	const int		Whether to invert trigger signal

Description

This filter is simple wrapper over Strobe::SetTriggerSource SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

VisionBox_StrobeSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets strobes software trigger.

Syntax

```
void avl::VisionBox_StrobeSoftwareTrigger
(
 VisionBox_State& ioState,
 const int inStrobeUnit,
 const bool inState
)
```

Parameters

	Name	Type	Default	Description
	ioState	VisionBox_State&		Object used to maintain state of the function.
	inStrobeUnit	const int		Number of strobe device to use
	inState	const bool		Set software trigger on or off

Description

This filter can be used to control strobes' trigger by software.

This filter is simple wrapper over Strobe::SwTrigger SDK function. Refer to AGE-X SDK to see how to use this function properly.

Remarks

Precondition for use of VisionBox filters is to have Imago Technologies AGE-X SKD installed on target computer. AGE-X SDK provides filters with necessary libraries (DLL files) and drivers. After installation of AGE-X SDK, system restart may be required.

Recommended AGE-X SDK version for Aurora Vision Studio usage is **1.6.8.0**.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

200. WebCamera

Table of content:

- WebCamera_GrabImage
- WebCamera_ListDevices

WebCamera_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame from a camera using Direct Show interface.

Applications: Not recommended for industrial operation.

Syntax

```
bool avl::WebCamera_GrabImage
(
 WebCamera_GrabImageState& ioState,
 atl::Optional<int> inCameraIndex,
 atl::Optional<const atl::String&> inCameraID,
 atl::Optional<avl::Size> inFrameSize,
 avl::WebCameraInputFormat::Type inPixelType,
 atl::Optional<int> inExposure,
 bool inExposureAuto,
 atl::Optional<int> inFocus,
 bool inFocusAuto,
 atl::Optional<int> inGain,
 atl::Optional<int> inBrightness,
 atl::Optional<int> inContrast,
 atl::Optional<int> inSaturation,
 atl::Optional<int> inWhiteBalance,
 bool inWhiteBalanceAuto,
 avl::Image& outFrame
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	WebCamera_GrabImageState&			Object used to maintain state of the function.
	inCameraIndex	Optional<int>	0 – +∞	NIL	Index number of the camera device to connect with
	inCameraID	Optional<const String&>		NIL	Unique ID of the camera device to connect with
	inFrameSize	Optional<Size>		NIL	Requested size of source frame in pixels selected from camera output formats
	inPixelType	WebCameraInputFormat::Type		Any	Requested specific pixel type from camera (may change image quality)
	inExposure	Optional<int>		NIL	Manual (fixed) exposure time in log base 2 seconds
	inExposureAuto	bool		False	Activates the automatic exposure time control by the camera
	inFocus	Optional<int>		NIL	Manual (fixed) focus point of the camera
	inFocusAuto	bool		False	Activates the automatic focus control by the camera
	inGain	Optional<int>		NIL	Camera gain value
	inBrightness	Optional<int>		NIL	Image brightness setting (black level value)
	inContrast	Optional<int>		NIL	Image contrast setting
	inSaturation	Optional<int>		NIL	Image saturation setting
	inWhiteBalance	Optional<int>		NIL	Manual (fixed) white balance setting
	inWhiteBalanceAuto	bool		False	Activates the automatic white balance control by the camera
	outFrame	Image&			Captured frame

Description

This filter uses DirectShow API to acquire images from devices registered in the system. Images can be acquired from many sources like: web cameras with support for DirectShow, video grabbers and system video streams.

The **inCameraIndex** input selects the capture device, out of multiple devices available in the system, by the numeric index in order provided by the operating system. This input can be used for quick experimental programs and is provided for backward compatibility, but it is advised to use the **inCameraID** input for selecting the camera instead as the numeric index is very unstable and can change frequently after hardware state changes in the system.

The **inCameraID** input specifies which web camera device in the system to use by the camera unique ID. Use the WebCamera_ListDevices filter to determine the camera ID. It is preferred to use this input instead of **inCameraIndex** as the unique ID of the camera is more stable in the system over time and can be, for example, used to save the camera selection in the application configuration.

Inputs **inCameraIndex** and **inCameraID** cannot be used at the same time (the device can be selected either by index or by ID, not both). Leaving both inputs unset will select the first video grabber in the system.

The **inFrameSize** input selects the output image size in pixels. If the requested size is not provided by the camera an error occurs. When this input is left unset the filter selects the first available size found.

inPixelType specifies what kind of pixel format should be preferred when selecting the output format from the camera. Selecting a format that the camera does not support will result in an error. Setting the input to "Any" will cause the filter to accept the first supported pixel format provided by the camera. The selected camera pixel format will be converted to the most appropriate format suitable for the vision application, including conversion from YUV to RGB color space.

Best quality of the image can be achieved using **inPixelType** with values **RGB24** or **RGB32**. Format **YUY2** stores two RGB pixels using only 4 bytes.

inExposure can be used to select a manually specified, fixed exposure time for the camera. This parameter is usually specified in base 2 log values and its valid range includes negative values (like -15 to 0) but the actual interpretation and range depends on the specific camera. Leaving this input unset (on "Auto") results in the camera setting to be left unchanged. This input is ignored when the **inExposureAuto** is set to True.

Setting the **inExposureAuto** input to True will result in enabling of the automatic control of the exposure time in the camera. Setting this input to False will leave the camera settings unchanged (use **inExposure** input to force a fixed exposure time value and to disable the automatic exposure control).

inFocus can be used to select a manually specified, fixed focus point for the cameras supporting dynamic focus control. This parameter is usually specified in millimeters to the target. Leaving this input unset (on "Auto") results in the camera setting to be left unchanged. This input is ignored when the **inFocusAuto** is set to True.

Setting the **inFocusAuto** input to True will result in enabling of the automatic focus control by the camera. Setting this input to False will leave the camera settings unchanged (use **inFocus** input to force a fixed focus point and to disable the automatic control).

inGain sets the gain value of the camera sensor (the sensitivity of the sensor). Leaving this input unset (on "Auto") results in the camera setting to be left unchanged. Some cameras might ignore this setting when automatic exposure control is active.

inBrightness sets the image brightness correction factor (the black level of the image). Leaving this input unset (on "Auto") results in the camera setting to be left unchanged.

inContrast sets the image contrast correction factor. Typically expressed as gain factor * 100 ranging from 0 to 10000, but the actual range depends on the camera. Leaving this input unset (on "Auto") results in the camera setting to be left unchanged.

inSaturation sets the image color saturation factor. Values typically range from 0 to 10000, but the actual range depends on the camera. Leaving this input unset (on "Auto") results in the camera setting to be left unchanged.

The **inWhiteBalance** input, when set, specifies a manual, fixed white balance factor. The interpretation of the value depends on the camera. Leaving this input unset (on "Auto") results in the camera setting to be left unchanged. This input is ignored when the **inWhiteBalanceAuto** is set to True.

Setting the **inWhiteBalanceAuto** input to True will enable the automatic white balance control in the camera. Setting this input to False will leave the camera settings unchanged (use **inWhiteBalance** input to force a fixed factor and to disable the automatic white balance control).

Various cameras might not support any of the image control settings like exposure, gain, brightness and white balance. Setting such input to non-default value when the camera does not support a given property will result in an IOError. Various cameras can also support different valid ranges for those parameters and setting a given input to values outside of the range supported by the camera will result in an IOError.

Remarks

To check which pixel types are supported you can use application GraphStudioNext.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

"Unable to connect with the web camera. No web camera devices found in the system." - no compatible video grabber device is present in the system.

"Unable to connect with the web camera. Camera with specified ID not found." - the unique ID specified on the **inCameraID** input is not valid or the camera with the specified ID is not present in the system.

"Unable to connect with the web camera. The camera device index might be out of a valid range." - provided **inCameraIndex** is not a valid device number (is outside of range of available devices).

"Unable to connect with the web camera. Ensure access to the camera is enabled in the system privacy settings." - access to the requested video grabber device was denied, possible due to the system and/or application privacy settings.

"Web Camera does not support the requested image format." - selected **inFrameSize** and/or **inPixelType** or their combination is not supported by the selected device.

"Unable to decode the Web Camera output stream" - the camera is outputting the images in the format that cannot be decoded by the filter.

List of possible exceptions:

Error type	Description
DomainError	Empty string of inCameraID specified in WebCamera_GrabImage.
DomainError	Inputs inCameraIndex and inCameraID cannot be used at the same time in WebCamera_GrabImage.

See Also

- WebCamera_ListDevices - Generates a list of web camera devices available in the system.

WebCamera_ListDevices

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a list of web camera devices available in the system.

Syntax

```
void avl::WebCamera_ListDevices
(
 WebCamera_GrabImageState& ioState,
 atl::Array<avl::WebCameraDevice>& outDevices
)
```

Parameters

	Name	Type	Default	Description
	ioState	WebCamera_GrabImageState&		Object used to maintain state of the function.
	outDevices	Array<WebCameraDevice>&		

Description

This filter generates a list of devices compatible with the WebCamera_GrabImage filter that are at the moment present in the system (installed and plugged in). A single device in a list is represented by a structure of two elements:

- **Name** - a friendly name intended to be displayed in the user interface. This value might not be unique in the system.
- **ID** - a unique identifier of the device, not intended to be readable by users, that can be used on the **inCameraID** input of the WebCamera_GrabImage filter.

- XiApi_SetParamFloat
- XiApi_SetParamInt
- XiApi_StartAcquisition
- XiApi_StopAcquisition

XiApi_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger for XIMEA device.

Syntax

```
void avl::XiApi_GenerateSoftwareTrigger
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_GetGPILevel

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Returns the value from selected GPI (digital input).

Syntax

```
void avl::XiApi_GetGPILevel
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 int inGPISelector,
 int& outGPILevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XIAPIState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
	inGPISelector	int	0 – +∞	1	GPI number
	outGPILevel	int&			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_GetParamFloat

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Float from XIMEA device.

Syntax

```
void avl::XiApi_GetParamFloat
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::String& inParameter,
 float& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index
	inParameter	const String&		Parameter name
	outValue	float&		Received value

Remarks

The value of the parameter is retrieved in every filter iteration.

The possible values (strings) of **inParameter** input can be found in the XIMEA documentation at the following website .

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_GetParamInt

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets parameter of type Integer from XIMEA device.

Syntax

```
void avl::XiApi_GetParamInt
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::String& inParameter,
 int& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index
	inParameter	const String&		Parameter name
	outValue	int&		Received value

Remarks

The value of the parameter is retrieved in every filter iteration.

The possible values (strings) of **inParameter** input can be found in the XIMEA documentation at the following website .

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a XIMEA camera.

Syntax

```
bool avl::XiApi_GrabImage
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 avl::XiApiImageDataFormat::Type inImageDataFormat,
 atl::Optional<const avl::XiApiTriggerSource::Type&> inTriggerSource,
 atl::Optional<const avl::XiApiDownsampling::Type&> inDownsampling,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<bool> inBadPixelCorrection,
 atl::Optional<bool> inAutomaticExposureGain,
 avl::Image& outImage,
 atl::int64& outFrameID,
 atl::int64& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XIAPIState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
	inImageDataFormat	XiApiImageDataFormat::Type			Output data format
	inTriggerSource	Optional<const XiApiTriggerSource::Type&>		NIL	Defines source of trigger
	inDownsampling	Optional<const XiApiDownsampling::Type&>		NIL	Changes image resolution by binning or skipping
	inExposureTime	Optional<int>	0 – +∞	NIL	Exposure time in microseconds
	inGain	Optional<float>		NIL	Gain in dB
	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
	inBadPixelCorrection	Optional<bool>		NIL	Correction of bad pixels
	inAutomaticExposureGain	Optional<bool>		NIL	Automatic exposure gain
	outImage	Image&			Captured frame
	outFrameID	int64&			Captured frame ID
	outTimestamp	int64&			Captured frame timestamp

Description

To be able to use a XIMEA camera, you need to install camera driver. You can find it at the following address (select binaries):

https://www.ximea.com/support/wiki/apis/XIMEA_API_Software_Package

Pleas make sure that xiApi SDK is properly installed on your computer. To verify the driver installation, you can run xiApiViewer.exe. If the camera was detected and you can see the image from it, you can use your XIMEA camera in Aurora Vision Studio.

Recommended xiApi SDK version for Aurora Vision Studio usage is **4.26**.

Setting parameters

All the auto parameters (those with checkboxes in the Property window) are initially set to the default values of the camera (they are not changed in Aurora Vision Studio). You can modify them by checking a checkbox and entering your own value.

The **inDeviceID** parameter is set only once when the filter is executed for the first time (if it set to Auto, the first available camera in the system will be used). All the other parameters are set during the first filter execution or when the parameter is changed (they are not set in every iteration when the value is not changed).

In **inAoi** parameter, the values of X, Y and Height should be even and the value of Width should be divisible by 4 or 16 (the exact value depends on the camera model).

To set more complex parameters, please use one of the following filters: XiApi_SetParamInt, XiApi_SetParamFloat. Please note, that if you set some parameter value in the XiApi_GrabImage filter you should not modify it by xiApi_SetParamXxx filter – it may cause problems.

Remarks

The full description of camera parameters can be found at the XIMEA website .

Alternatively you can also use GenICam filters to work with XIMEA cameras. Please refer to the article Working with Gen TL devices.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

XiApi_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image from a XIMEA camera.

Syntax

```
bool avl::XiApi_GrabImage_WithTimeout
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 int inTimeout,
 avl::XiApiImageDataFormat::Type inImageDataFormat,
 atl::Optional<const avl::XiApiTriggerSource::Type&> inTriggerSource,
 atl::Optional<const avl::XiApiDownsampling::Type&> inDownsampling,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<bool> inBadPixelCorrection,
 atl::Optional<bool> inAutomaticExposureGain,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<atl::int64>& outFrameID,
 atl::Conditional<atl::int64>& outTimestamp
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XIAPIState&			Object used to maintain state of the function.
→	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
→	inTimeout	int	0 – ∞	100	Maximum time to wait for frame in milliseconds
→	inImageDataFormat	XiApiImageDataFormat::Type			Output data format
→	inTriggerSource	Optional<const XiApiTriggerSource::Type&>		NIL	Defines source of trigger
→	inDownsampling	Optional<const XiApiDownsampling::Type&>		NIL	Changes image resolution by binning or skipping
→	inExposureTime	Optional<int>	0 – + ∞	NIL	Exposure time in microseconds
→	inGain	Optional<float>		NIL	Gain in dB
→	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
→	inBadPixelCorrection	Optional<bool>		NIL	Correction of bad pixels
→	inAutomaticExposureGain	Optional<bool>		NIL	Automatic exposure gain
←	outImage	Conditional<Image>&			Captured frame
←	outFrameID	Conditional<int64>&			Captured frame ID
←	outTimestamp	Conditional<int64>&			Captured frame timestamp

- XiApi_StopAcquisition – Stops image acquisition in a camera.
- XiApi_SetGPIMode – Defines selected GPI (digital input) functionality.
- XiApi_GetGPILevel – Returns the value from selected GPI (digital input).
- XiApi_SetGPOMode – Defines GPO (digital output) functionality.
- XiApi_SetParamInt – Sets parameter of type Integer in XIMEA device.
- XiApi_SetParamFloat – Sets parameter of type Float in XIMEA device.
- XiApi_GetParamInt – Gets parameter of type Integer from XIMEA device.
- XiApi_GetParamFloat – Gets parameter of type Float from XIMEA device.
- XiApi_GenerateSoftwareTrigger – Generates software trigger for XIMEA device.

XiApi_SetGPIMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Defines selected GPI (digital input) functionality.

Syntax

```
void avl::XiApi_SetGPIMode
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 int inGPISelector,
 avl::XiApiGPIMode::Type inGPIMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XIAPIState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
	inGPISelector	int	0 – +∞	1	GPI number
	inGPIMode	XiApiGPIMode::Type			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_SetGPOMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Defines GPO (digital output) functionality.

Syntax

```
void avl::XiApi_SetGPOMode
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 int inGPOSelector,
 avl::XiApiGPOMode::Type inGPOMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XIAPIState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
	inGPOSelector	int	0 – + ∞	1	GPO number
	inGPOMode	XiApiGPOMode::Type			

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_SetParamFloat

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Float in XIMEA device.

Syntax

```
void avl::XiApi_SetParamFloat
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::String& inParameter,
 float inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index
	inParameter	const String&		Parameter name
	inValue	float		Value to set

Remarks

The value of the parameter is set in every filter iteration. Please note, that if you set some parameter value in this filter you should not modify it by XiApi_GrabImage filter - it may cause problems.

The possible values (strings) of **inParameter** input can be found in the XIMEA documentation at the following website .

The full description of camera parameters can be found at the XIMEA website .

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_SetParamInt

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets parameter of type Integer in XIMEA device.

Syntax

```
void avl::XiApi_SetParamInt
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 const atl::String& inParameter,
 int inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index
	inParameter	const String&		Parameter name
	inValue	int		Value to set

Remarks

The value of the parameter is set in every filter iteration. Please note, that if you set some parameter value in this filter you should not modify it by XiApi_GrabImage filter - it may cause problems.

The possible values (strings) of **inParameter** input can be found in the XIMEA documentation at the following website .

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::XiApi_StartAcquisition
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID,
 avl::XiApiImageDataFormat::Type inImageDataFormat,
 atl::Optional<const avl::XiApiTriggerSource::Type&> inTriggerSource,
 atl::Optional<const avl::XiApiDownsampling::Type&> inDownsampling,
 atl::Optional<int> inExposureTime,
 atl::Optional<float> inGain,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<bool> inBadPixelCorrection,
 atl::Optional<bool> inAutomaticExposureGain
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XIAPIState&			Object used to maintain state of the function.
	inDeviceID	const Optional<String>&		NIL	Camera chip ID or camera index
	inImageDataFormat	XiApiImageDataFormat::Type			Output data format
	inTriggerSource	Optional<const XiApiTriggerSource::Type&>		NIL	Defines source of trigger
	inDownsampling	Optional<const XiApiDownsampling::Type&>		NIL	Changes image resolution by binning or skipping
	inExposureTime	Optional<int>	0 – +∞	NIL	Exposure time in microseconds
	inGain	Optional<float>		NIL	Gain in dB
	inAoi	Optional<const Box&>		NIL	Required fragment of image to stream
	inBadPixelCorrection	Optional<bool>		NIL	Correction of bad pixels
	inAutomaticExposureGain	Optional<bool>		NIL	Automatic exposure gain

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

XiApi_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::XiApi_StopAcquisition
(
 XIAPIState& ioState,
 const atl::Optional<atl::String>& inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	XIAPIState&		Object used to maintain state of the function.
	inDeviceID	const Optional<String>&	NIL	Camera chip ID or camera index

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

202. XSightSmartCamera

Table of content:

- XSightSmartCamera_GenerateSoftwareTrigger

XSightSmartCamera_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates software trigger.

Syntax

```
void avl::XSightSmartCamera_GenerateSoftwareTrigger
(
 XSightSmartCamera_State& ioState,
 atl::Optional<int> inDeviceIndex,
 bool inGenerate
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSightSmartCamera_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inGenerate	bool		True	

Remarks

Camera driver software

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight smart camera identifying internal index.

Camera device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight smart camera SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0**.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- XSightSmartCamera_StartAcquisition – Starts image acquisition.

XSightSmartCamera_GetDigitalInput

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets digital input.

Syntax

```
void avl::XSightSmartCamera_GetDigitalInput
(
 XSightSmartCamera_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outValue
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSightSmartCamera_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inPort	int	1 – 4		
←	outValue	bool&			

Remarks

Camera driver software

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight smart camera identifying internal index.

XSightSmartCamera_GrabImage

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using X-Sight smart camera.

Syntax

```
bool avl::XSightSmartCamera_GrabImage
(
 XSightSmartCamera_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inInputQueueSize,
 atl::Optional<const avl::XSightSmartCameraImageFormat&> inImageFormat,
 atl::Optional<int> inExposureTime,
 atl::Optional<int> inFrameRate,
 atl::Optional<bool> inGainAuto,
 atl::Optional<const atl::Array<int>&> inGain,
 atl::Optional<int> inBlackLevel,
 atl::Optional<bool> inWhiteBalanceAuto,
 atl::Optional<int> inContrast,

 atl::Optional<int> inLumination,
 atl::Optional<int> inSaturation,
 atl::Optional<int> inHUE,
 atl::Optional<int> inColorCorrection,
 atl::Optional<int> inSharpness,
 atl::Optional<bool> inTriggerMode,
 atl::Optional<const avl::XSightSmartCameraTriggerConfiguration&> inTriggerConfiguration,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSightSmartCamera_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>		NIL	Device identifying number
	inInputQueueSize	int	1 – ∞	5	Capacity of output frames queue
	inImageFormat	Optional<const XSightSmartCameraImageFormat&>		NIL	
	inExposureTime	Optional<int>	1 – ∞	NIL	Exposure time in milliseconds
	inFrameRate	Optional<int>	1 – ∞	NIL	
	inGainAuto	Optional<bool>		NIL	
	inGain	Optional<const Array<int>&>		NIL	
	inBlackLevel	Optional<int>	1 – ∞	NIL	
	inWhiteBalanceAuto	Optional<bool>		NIL	
	inContrast	Optional<int>	1 – 128	NIL	
	inGamma	Optional<int>	0 – ∞	NIL	
	inLumination	Optional<int>	1 – 128	NIL	
	inSaturation	Optional<int>	1 – ∞	NIL	
	inHUE	Optional<int>	1 – ∞	NIL	
	inColorCorrection	Optional<int>	1 – ∞	NIL	
	inSharpness	Optional<int>	1 – ∞	NIL	
	inTriggerMode	Optional<bool>		NIL	
	inTriggerConfiguration	Optional<const XSightSmartCameraTriggerConfiguration&>		NIL	
	outImage	Image&			Captured image

Remarks

- **Device Index** – X-Sight smart camera identifying internal index.

Camera device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight smart camera SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0**.

All the other parameters exposed by camera filters are optional, setting them to 'Auto' leaves related parameter unchanged in camera (device default or user set configuration).

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSightSmartCamera_StartAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Starts image acquisition.

Syntax

```
void avl::XSightSmartCamera_StartAcquisition
(
 XSightSmartCamera_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inInputQueueSize,
 atl::Optional<const avl::XSightSmartCameraImageFormat&> inImageFormat,
 atl::Optional<int> inExposureTime,
 atl::Optional<int> inFrameRate,
 atl::Optional<bool> inGainAuto,
 atl::Optional<const atl::Array<int>&> inGain,
 atl::Optional<int> inBlackLevel,
 atl::Optional<bool> inWhiteBalanceAuto,
 atl::Optional<int> inContrast,
 atl::Optional<int> inGamma,
 atl::Optional<int> inLumination,
 atl::Optional<int> inSaturation,
 atl::Optional<int> inHUE,
 atl::Optional<int> inColorCorrection,
 atl::Optional<int> inSharpness,
 atl::Optional<bool> inTriggerMode,
 atl::Optional<const avl::XSightSmartCameraTriggerConfiguration&> inTriggerConfiguration
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSightSmartCamera_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inInputQueueSize	int	1 – ∞	5	Capacity of output frames queue
	inImageFormat	Optional<const XSightSmartCameraImageFormat&>		NIL	
	inExposureTime	Optional<int>	1 – ∞	NIL	Exposure time in milliseconds
	inFrameRate	Optional<int>	1 – ∞	NIL	
	inGainAuto	Optional<bool>		NIL	
	inGain	Optional<const Array<int>&>		NIL	
	inBlackLevel	Optional<int>	1 – ∞	NIL	
	inWhiteBalanceAuto	Optional<bool>		NIL	
	inContrast	Optional<int>	1 – 128	NIL	
	inGamma	Optional<int>	0 – ∞	NIL	
	inLumination	Optional<int>	1 – 128	NIL	
	inSaturation	Optional<int>	1 – ∞	NIL	
	inHUE	Optional<int>	1 – ∞	NIL	
	inColorCorrection	Optional<int>	1 – ∞	NIL	
	inSharpness	Optional<int>	1 – ∞	NIL	
	inTriggerMode	Optional<bool>		NIL	
	inTriggerConfiguration	Optional<const XSightSmartCameraTriggerConfiguration&>		NIL	

Remarks

Camera driver software

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** - X-Sight smart camera identifying internal index.

Camera device driver software

XSightSmartCamera_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition.

Syntax

```
void avl::XSightSmartCamera_StopAcquisition
(
 XSightSmartCamera_State& ioState,
 atl::Optional<int> inDeviceIndex
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSightSmartCamera_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 - ∞	NIL	Device identifying number

XSight_GetCompareStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder stop.

Syntax

```
void avl::XSight_GetCompareStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 bool& outFinished,
 int& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	
	outFinished	bool&			
	outCount	int&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderCaptureConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder capture configuration.

Syntax

```
void avl::XSight_GetEncoderCaptureConfiguration
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int& outPort,
 int& outEncoder
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	outPort	int&			Trigger input signal
	outEncoder	int&			Captured encoder channel

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderCaptureCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder capture count.

Syntax

```
void avl::XSight_GetEncoderCaptureCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 atl::int64& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	outCount	int64&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderCaptureStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets compare status.

Syntax

```
void avl::XSight_GetEncoderCaptureStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 bool& outActive
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	outActive	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder counter.

Syntax

```
void avl::XSight_GetEncoderCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 atl::int64& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	outCount	int64&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderDirection

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder direction.

Syntax

```
void avl::XSight_GetEncoderDirection
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightEncoderDirection::Type& outDirection
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 16	1	Encoder channel
←	outDirection	XSightEncoderDirection::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderEnable

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder enable status.

Syntax

```
void avl::XSight_GetEncoderEnable
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 bool& outEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	outEnable	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetEncoderSide

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets encoder side.

Syntax

```
void avl::XSight_GetEncoderSide
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightEncoderSide::Type& outSide
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 16	1	Encoder channel
←	outSide	XSightEncoderSide::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetInputCounter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets input port counter value.

Syntax

```
void avl::XSight_GetInputCounter
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outCount	int&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetInputFilter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets input filter property.

Syntax

```
void avl::XSight_GetInputFilter
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int& outFilterTime
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outFilterTime	int&			Filter time in us unit.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetInputInvertMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets input port inverse property.

Syntax

```
void avl::XSight_GetInputInvertMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outInvert
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	outInvert	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetInputMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads input port working mode.

Syntax

```
void avl::XSight_GetInputMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightInputMode::Type& outMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	outMode	XSightInputMode::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputInvertMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output port inverse property.

Syntax

```
void avl::XSight_GetOutputInvertMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outInvert
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	outInvert	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputLatchCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output latch count.

Syntax

```
void avl::XSight_GetOutputLatchCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 atl::int64& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outCount	int64&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputLatchStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output latch status.

Syntax

```
void avl::XSight_GetOutputLatchStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outFinished
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outFinished	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output port working mode.

Syntax

```
void avl::XSight_GetOutputMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightOutputMode::Type& outMode
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inPort	int	1 – 16	1	IO port description number.
←	outMode	XSightOutputMode::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputPulseBufferStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output pulse buffer status.

Syntax

```
void avl::XSight_GetOutputPulseBufferStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outFull
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outFull	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputPulseConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output pulse configuration.

Syntax

```
void avl::XSight_GetOutputPulseConfiguration
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 atl::int64& outDelay,
 atl::int64& outWidth,
 atl::int64& outCycle,
 atl::int64& outCount,
 int& outSource
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	Output port description number.
←	outDelay	int64&			Output delay in us unit.
←	outWidth	int64&			Pulse width in us unit.
←	outCycle	int64&			Pulse cycle in us unit.
←	outCount	int64&			
←	outSource	int&			Source index depends on port operation mode

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputPulseCount

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output pulse count.

Syntax

```
void avl::XSight_GetOutputPulseCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 atl::int64& outCount
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outCount	int64&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputPulseRunStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output pulse run status.

Syntax

```
void avl::XSight_GetOutputPulseRunStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outReady
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
→	inPort	int	1 – 16	1	IO port description number.
←	outReady	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetOutputPulseStatus

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output pulse status.

Syntax

```
void avl::XSight_GetOutputPulseStatus
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool& outOverflow
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	IO port description number.
	outOverflow	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetPWMFlashTime

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets PWM flash time.

Syntax

```
void avl::XSight_GetPWMFlashTime
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 atl::int64& outTime
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 6	1	PWM channel description number.
←	outTime	int64&			Time in us unit.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetPWMParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets PWM channel parameters.

Syntax

```
void avl::XSight_GetPWMParameters
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int& outFrequency,
 int& outDutyCycle
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 6	1	PWM channel description number.
←	outFrequency	int&			Output frequency as Hz.
←	outDutyCycle	int&			Duty cycle.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetPWMState

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets PWM state.

Syntax

```
void avl::XSight_GetPWMState
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 bool& outEnable
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 6	1	PWM channel description number.
←	outEnable	bool&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetPWMTriggerMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets PWM channel working mode.

Syntax

```
void avl::XSight_GetPWMTriggerMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightPWMTrigger::Type& outMode
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 6	1	PWM channel description number.
←	outMode	XSightPWMTrigger::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_GetPWMTriggerSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets PWM trigger source.

Syntax

```
void avl::XSight_GetPWMTriggerSource
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int& outPort
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	XSight_State&			Object used to maintain state of the function.
→	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
→	inChannel	int	1 – 6	1	PWM channel description number.
←	outPort	int&			Input port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_OpenDevice

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Opens IO device.

Syntax

```
void avl::XSight_OpenDevice
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ReadInputLevel_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads input port levels from device in one routine.

Syntax

```
void avl::XSight_ReadInputLevel_Multiple
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Array<avl::XSightIOLevel::Type>& outLevels
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	outLevels	Array<XSightIOLevel::Type>&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ReadInputLevel_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads input port level from device.

Syntax

```
void avl::XSight_ReadInputLevel_Single
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightIOLevel::Type& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	outLevel	XSightIOLevel::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ReadOutputLevel_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads output port levels from device in one routine.

Syntax

```
void avl::XSight_ReadOutputLevel_Multiple
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 atl::Array<avl::XSightIOLevel::Type>& outLevels
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	outLevels	Array<XSightIOLevel::Type>&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ReadOutputLevel_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Reads output port level from device.

Syntax

```
void avl::XSight_ReadOutputLevel_Single
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightIOLevel::Type& outLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	outLevel	XSightIOLevel::Type&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ResetEncoderCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets encoder counter.

Syntax

```
void avl::XSight_ResetEncoderCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ResetInputCounter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets input port counter value.

Syntax

```
void avl::XSight_ResetInputCounter
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_ResetOutputPulseCount

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Resets output pulse count.

Syntax

```
void avl::XSight_ResetOutputPulseCount
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	IO port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetCompareDataStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets compare data.

Syntax

```
void avl::XSight_SetCompareDataStart
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inCount
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – ∞	1	
	inCount	int	1 – 15		

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetCompareGTStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets compare greater than.

Syntax

```
void avl::XSight_SetCompareGTStart
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inPosition
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	
	inPosition	int			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetCompareLinearStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets compare linear stop.

Syntax

```
void avl::XSight_SetCompareLinearStart
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inStartPosition,
 int inRepeatTimes,
 int inInterval
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – ∞	1	Encoder channel
	inStartPosition	int			The first comparison position
	inRepeatTimes	int	0 – 15		Number of comparison, 0 means unlimited comparison times
	inInterval	int	0 – ∞	1	

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetCompareStop

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder stop.

Syntax

```
void avl::XSight_SetCompareStop
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderCaptureConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder capture configuration.

Syntax

```
void avl::XSight_SetEncoderCaptureConfiguration
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inPort,
 int inEncoder
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	inPort	int	1 – 16	1	Trigger input signal
	inEncoder	int	0 – 16	0	Captured encoder channel

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderCaptureStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder start.

Syntax

```
void avl::XSight_SetEncoderCaptureStart
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderCaptureStop

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder stop.

Syntax

```
void avl::XSight_SetEncoderCaptureStop
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderDirection

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder direction.

Syntax

```
void avl::XSight_SetEncoderDirection
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightEncoderDirection::Type inDirection
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	inDirection	XSightEncoderDirection::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderEnable

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder enable status.

Syntax

```
void avl::XSight_SetEncoderEnable
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	inEnable	bool		True	

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetEncoderSide

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets encoder side.

Syntax

```
void avl::XSight_SetEncoderSide
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightEncoderSide::Type inSide
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 16	1	Encoder channel
	inSide	XSightEncoderSide::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetInputFilter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Setups input filter.

Syntax

```
void avl::XSight_SetInputFilter
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int inFilterTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	IO port description number.
	inFilterTime	int	0 – ∞	100	Filter time in us unit.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetInputInvertMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets input port inverse property.

Syntax

```
void avl::XSight_SetInputInvertMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool inInvert
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	inInvert	bool		True	

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetInputMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets input port working mode.

Syntax

```
void avl::XSight_SetInputMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightInputMode::Type inMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	inMode	XSightInputMode::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputInvertMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output port inverse property.

Syntax

```
void avl::XSight_SetOutputInvertMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool inInvert
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	inInvert	bool		True	

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputLatchEnable

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output latch enable.

Syntax

```
void avl::XSight_SetOutputLatchEnable
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 bool inEnable
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	Output port description number.
	inEnable	bool			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputLatchSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output latch source.

Syntax

```
void avl::XSight_SetOutputLatchSource
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int inTriggerSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	Output port description number.
	inTriggerSource	int	1 – 16	1	Input port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets output port working mode.

Syntax

```
void avl::XSight_SetOutputMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightOutputMode::Type inMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	inMode	XSightOutputMode::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputPulse

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output pulse.

Syntax

```
void avl::XSight_SetOutputPulse
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int inDelay,
 int inPulseWidth
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	IO port description number.
	inDelay	int	0 – ∞	0	Output delay in us unit.
	inPulseWidth	int	1 – ∞	100	Pulse width in us unit.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

This function is old way to start pulse. Use XSight_SetOutputPulseSoft.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputPulseConfiguration

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output pulse configuration.

Syntax

```
void avl::XSight_SetOutputPulseConfiguration
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 atl::int64 inDelay,
 atl::int64 inWidth,
 atl::int64 inCycle,
 atl::int64 inCount,
 int inSource
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	Output port description number.
	inDelay	int64	0 – ∞	0L	Output delay in us unit.
	inWidth	int64	1 – ∞	100L	Pulse width in us unit.
	inCycle	int64	0 – ∞	0L	Pulse cycle in us unit.
	inCount	int64	0 – ∞	0L	
	inSource	int	0 – ∞	1	Source index depends on port operation mode

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputPulseSoft

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output pulse soft.

Syntax

```
void avl::XSight_SetOutputPulseSoft
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	Output port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Use this function with XSight_SetOutputPulseConfiguration.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetOutputPulseTriggered

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets output pulse triggered by input port.

Syntax

```
void avl::XSight_SetOutputPulseTriggered
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 int inDelay,
 int inPulseWidth,
 int inTriggerPort,
 avl::XSightTriggerEdge::Type inTriggerEdge
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number.
	inPort	int	1 – 16	1	IO port description number.
	inDelay	int	0 – ∞	0	Output delay in us unit.
	inPulseWidth	int	1 – ∞	100	Pulse width in us unit.
	inTriggerPort	int	1 – 16	1	Input port description number.
	inTriggerEdge	XSightTriggerEdge::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMFlashTime

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM flash time.

Syntax

```
void avl::XSight_SetPWMFlashTime
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 atl::int64 inTime
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.
	inTime	int64	0 – ∞	10000L	Time in us unit.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMParameters

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM channel parameters.

Syntax

```
void avl::XSight_SetPWMParameters
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inFrequency,
 int inDutyCycle
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.
	inFrequency	int	1 – 500000	10000	Output frequency as Hz.
	inDutyCycle	int	0 – 127	1	Duty cycle.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMStart

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM channel on.

Syntax

```
void avl::XSight_SetPWMStart
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMStop

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM channel off.

Syntax

```
void avl::XSight_SetPWMStop
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMTriggerMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM channel working mode.

Syntax

```
void avl::XSight_SetPWMTriggerMode
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 avl::XSightPWMTrigger::Type inMode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.
	inMode	XSightPWMTrigger::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_SetPWMTriggerSource

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets PWM trigger source.

Syntax

```
void avl::XSight_SetPWMTriggerSource
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inChannel,
 int inPort
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inChannel	int	1 – 6	1	PWM channel description number.
	inPort	int			Input port description number.

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Add DLL path to system environment variable is required.

Recommended Runtime version for Aurora Vision Studio usage is **1.0.0**.

Invoking I/O port filters who force specifics behaviour (for example, set output level) may also change I/O mode to fitted.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_WriteOutputLevel_Multiple

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes output port levels to device in one routine.

Syntax

```
void avl::XSight_WriteOutputLevel_Multiple
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 const atl::Array<avl::XSightIOLevel::Type>& inLevels
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inLevels	const Array<XSightIOLevel::Type>&			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

XSight_WriteOutputLevel_Single

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Writes output port levels to device.

Syntax

```
void avl::XSight_WriteOutputLevel_Single
(
 XSight_State& ioState,
 atl::Optional<int> inDeviceIndex,
 int inPort,
 avl::XSightIOLevel::Type inLevel
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	XSight_State&			Object used to maintain state of the function.
	inDeviceIndex	Optional<int>	0 – ∞	NIL	Device identifying number
	inPort	int	1 – 16	1	IO port description number.
	inLevel	XSightIOLevel::Type			

Remarks

Device identification

inDeviceIndex can be used to pick one of multiple devices connected to the computer. **inDeviceIndex** can be set to:

- **Device Index** – X-Sight I/O device identifying internal index.

I/O device driver software

This filter is intended to cooperate with a device using its vendor SDK. To be able to connect to a device, it is required to install X-Sight SDK.

Also in AVL Lite

ZebraCVCameras_ExecuteCommand

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Executes command

Syntax

```
void avl::ZebraCVCameras_ExecuteCommand
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inCommand
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inCommand	const String&		Parameter name

Also in AVL Lite

ZebraCVCameras_FindDevices

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Finds devices reachable from this system.

Syntax

```
void avl::ZebraCVCameras_FindDevices
(
 ZebraCVCameras_State& ioState,
 atl::Optional<int> inDetectionTimeout,
 atl::Array<avl::EBUSDeviceInfo>& outDevices
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraCVCameras_State&			Object used to maintain state of the function.
	inDetectionTimeout	Optional<int>	100 – 60000	NIL	Sets the time to search the system devices in ms.
	outDevices	Array<EBUSDeviceInfo>&			

ZebraCVCameras_GenerateSoftwareTrigger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger.

Syntax

```
void avl::ZebraCVCameras_GenerateSoftwareTrigger
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

ZebraCVCameras_GetBooleanParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a boolean parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetBooleanParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	bool&		Parameter value

ZebraCVCameras_GetEnumParameterAsInteger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enum parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetEnumParameterAsInteger
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		Parameter value

ZebraCVCameras_GetEnumParameterAsString

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an enum parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetEnumParameterAsString
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	String&		Parameter value

ZebraCVCameras_GetFloatParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a float parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetFloatParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	double&		Parameter value

Also in AVL Lite

ZebraCVCameras_GetIntegerParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets an integer parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetIntegerParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	int64&		Parameter value

Also in AVL Lite

ZebraCVCameras_GetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Gets a string parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_GetStringParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	outValue	String&		Parameter value

Also in AVL Lite

ZebraCVCameras_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using a ZebraCVCameras device.

Syntax

```
bool avl::ZebraCVCameras_GrabImage
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<avl::EBUSPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<avl::EBUSAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::EBUSAutoExposureMode::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<avl::EBUSAutoGainMode::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<avl::EBUSTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::EBUSTriggerActivation::Type> inTriggerActivation,
 bool inSkipInvalidFrames,
 bool inTryReconnection,
 avl::Image& outImage,
 avl::EBUSFrameData& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ZebraCVCameras_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<const String&>		NIL	Device identifying number
→	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
→	inPixelFormat	Optional<EBUSPixelFormat::Type>		NIL	Image pixel format
→	inAoi	Optional<const Box&>		NIL	Area of interest
→	inAcquisitionMode	Optional<EBUSAcquisitionMode::Type>		NIL	Acquisition mode
→	inAcquisitionFrameCount	Optional<int>	1 – 65535	NIL	Number of frames to acquire in MultiFrame acquisition mode
→	inFrameRate	Optional<double>	0.125D – ∞	NIL	Acquisition frame rate
→	inExposureAuto	Optional<EBUSAutoExposureMode::Type>		NIL	Automatic exposure mode
→	inExposureTime	Optional<double>	1.0D – ∞	NIL	Exposure time in us
→	inGainAuto	Optional<EBUSAutoGainMode::Type>		NIL	Automatic gain mode
→	inGain	Optional<double>	1.0D – ∞	NIL	Gain as an absolute physical value
→	inTriggerSource	Optional<EBUSTriggerSource::Type>		NIL	Trigger source
→	inTriggerActivation	Optional<EBUSTriggerActivation::Type>		NIL	Trigger activation mode
→	inSkipInvalidFrames	bool		True	Skipping invalid images
→	inTryReconnection	bool		True	Try to reconnect if the camera is disconnected
←	outImage	Image&			Captured frame
←	outFrameData	EBUSFrameData&			Captured frame data

Remarks

Camera driver software

This filter is intended to cooperate with a **CV60** camera using its vendor SDK. To be able to connect to a camera, it is required to install proper SDK with camera dedicated drivers.

Please contact our technical support to obtain the SDK 6.5.1 version.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, the first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **Serial Number** – should be printed on the device housing.
- **Device ID** – unique device identifier.
- **IP Address** – network IP address of device.
- **MAC Address** – MAC address of device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- ZebraCVCameras_GrabImage_WithTimeout – Captures an image using a ZebraCVCameras device with timeout.
- ZebraCVCameras_StartAcquisition – Initializes and starts image acquisition in a camera.

Also in AVL Lite

ZebraCVCameras_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures an image using a ZebraCVCameras device with timeout.

Syntax

```
bool avl::ZebraCVCameras_GrabImage_WithTimeout
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inTimeout,
 int inInputQueueSize,
 atl::Optional<avl::EBUSPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<avl::EBUSAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::EBUSAutoExposureMode::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<avl::EBUSAutoGainMode::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<avl::EBUSTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::EBUSTriggerActivation::Type> inTriggerActivation,
 bool inSkipInvalidFrames,
 bool inTryReconnection,
 atl::Conditional<avl::Image>& outImage,
 atl::Conditional<avl::EBUSFrameData>& outFrameData
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraCVCameras_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inTimeout	int	100 – ∞	100	Maximum time to wait for frame in milliseconds
	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
	inPixelFormat	Optional<EBUSPixelFormat::Type>		NIL	Image pixel format
	inAoi	Optional<const Box&>		NIL	Area of interest
	inAcquisitionMode	Optional<EBUSAcquisitionMode::Type>		NIL	Acquisition mode
	inAcquisitionFrameCount	Optional<int>	1 – 65535	NIL	Number of frames to acquire in MultiFrame acquisition mode
	inFrameRate	Optional<double>	0.125D – ∞	NIL	Acquisition frame rate

ZebraCVCameras_SetBooleanParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a boolean parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetBooleanParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 bool inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	bool		Parameter value

ZebraCVCameras_SetEnumParameterAsInteger

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an enum parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetEnumParameterAsInteger
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	int64		Parameter value

ZebraCVCameras_SetEnumParameterAsString

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an enum parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetEnumParameterAsString
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	const String&		Parameter value

ZebraCVCameras_SetFloatParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a float parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetFloatParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 double inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	double		Parameter value

ZebraCVCameras_SetIntegerParameter

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets an integer parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetIntegerParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 atl::int64 inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	int64		Parameter value

ZebraCVCameras_SetStringParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Sets a string parameter of the ZebraCVCameras device.

Syntax

```
void avl::ZebraCVCameras_SetStringParameter
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 const atl::String& inName,
 const atl::String& inValue
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number
	inName	const String&		Parameter name
	inValue	const String&		Parameter value

Also in AVL Lite

ZebraCVCameras_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a camera.

Syntax

```
void avl::ZebraCVCameras_StartAcquisition
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID,
 int inInputQueueSize,
 atl::Optional<avl::EBUSPixelFormat::Type> inPixelFormat,
 atl::Optional<const avl::Box&> inAoi,
 atl::Optional<avl::EBUSAcquisitionMode::Type> inAcquisitionMode,
 atl::Optional<int> inAcquisitionFrameCount,
 atl::Optional<double> inFrameRate,
 atl::Optional<avl::EBUSAutoExposureMode::Type> inExposureAuto,
 atl::Optional<double> inExposureTime,
 atl::Optional<avl::EBUSAutoGainMode::Type> inGainAuto,
 atl::Optional<double> inGain,
 atl::Optional<avl::EBUSTriggerSource::Type> inTriggerSource,
 atl::Optional<avl::EBUSTriggerActivation::Type> inTriggerActivation
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraCVCameras_State&			Object used to maintain state of the function.
	inDeviceID	Optional<const String&>		NIL	Device identifying number
	inInputQueueSize	int	1 – ∞	12	Capacity of output frames queue
	inPixelFormat	Optional<EBUSPixelFormat::Type>		NIL	Image pixel format
	inAoi	Optional<const Box&>		NIL	Area of interest
	inAcquisitionMode	Optional<EBUSAcquisitionMode::Type>		NIL	Acquisition mode
	inAcquisitionFrameCount	Optional<int>	1 – 65535	NIL	Number of frames to acquire in MultiFrame acquisition mode
	inFrameRate	Optional<double>	0.125D – ∞	NIL	Acquisition frame rate
	inExposureAuto	Optional<EBUSAutoExposureMode::Type>		NIL	Automatic exposure mode
	inExposureTime	Optional<double>	1.0D – ∞	NIL	Exposure time in us
	inGainAuto	Optional<EBUSAutoGainMode::Type>		NIL	Automatic gain mode
	inGain	Optional<double>	1.0D – ∞	NIL	Gain as an absolute physical value
	inTriggerSource	Optional<EBUSTriggerSource::Type>		NIL	Trigger source
	inTriggerActivation	Optional<EBUSTriggerActivation::Type>		NIL	Trigger activation mode

Remarks

Camera driver software

This filter is intended to cooperate with a **CV60** camera using its vendor SDK. To be able to connect to a camera, it is required to install proper SDK with camera dedicated drivers.

Please contact our technical support to obtain the SDK 6.5.1 version.

Add DLL path to system environment variable may be required.

Camera identification

When there is only one camera connected to a computer, field **inDeviceID** can be set to Auto. In this case, the first available camera will be found and connected.

inDeviceID field can be used to pick one of multiple cameras connected to the computer. DeviceID can be set to:

- **Serial Number** – should be printed on the device housing.
- **Device ID** – unique device identifier.
- **IP Address** – network IP address of device.
- **MAC Address** – MAC address of device.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

- ZebraCVCameras_GrabImage_WithTimeout – Captures an image using a ZebraCVCameras device with timeout.

ZebraCVCameras_StopAcquisition

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a camera.

Syntax

```
void avl::ZebraCVCameras_StopAcquisition
(
 ZebraCVCameras_State& ioState,
 atl::Optional<const atl::String&> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraCVCameras_State&		Object used to maintain state of the function.
	inDeviceID	Optional<const String&>	NIL	Device identifying number

205. ZebraScanEngines

Also in AVL Lite

ZebraScanEngines_BeepBuzzer

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Beeps the in-built buzzer according to the beep code.

Syntax

```
void avl::ZebraScanEngines_BeepBuzzer
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::ZebraScanEnginesBeepCodes::Type inBeepCode
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inBeepCode	ZebraScanEnginesBeepCodes::Type			Buzzer beep pattern

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

ZebraScanEngines_ControlAim

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Turns device aim on or off.

Syntax

```
void avl::ZebraScanEngines_ControlAim
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 bool inTurnOn
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inTurnOn	bool			Turn aim on or off.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

ZebraScanEngines_ControlLeds

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Turns device LEDs on and off.

Syntax

```
void avl::ZebraScanEngines_ControlLeds
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::ZebraScanEnginesLeds::Type inLedAction
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inLedAction	ZebraScanEnginesLeds::Type			LED action to perform

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

ZebraScanEngines_GenerateSoftwareTrigger

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Generates a software trigger.

Syntax

```
void avl::ZebraScanEngines_GenerateSoftwareTrigger
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 bool inRelease
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inRelease	bool			Whether to pull or to release the trigger

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_GetParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Get parameter of a specified scanner.

Syntax

```
void avl::ZebraScanEngines_GetParameter
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 int inParameterID,
 atl::String& outParameterType,
 atl::String& outParameterValue
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
→	inParameterID	int	0 – ∞		Attribute number
←	outParameterType	String&			Attribute type
←	outParameterValue	String&			Attribute value

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_GrabImage

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using a Zebra scanner.

Syntax

```
bool avl::ZebraScanEngines_GrabImage
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 bool inAutoTrigger,
 atl::Optional<int> inAutoTriggerPeriod,
 avl::ZebraScanEnginesOperationModes::Type inOperationMode,
 avl::ZebraScanEnginesImageTypes::Type inImageType,
 avl::Image& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↻	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
→	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
→	inAutoTrigger	bool		True	Enables or disables auto triggering
→	inAutoTriggerPeriod	Optional<int>	10 – ∞	NIL	Period of automatic triggers (in ms)
→	inOperationMode	ZebraScanEnginesOperationModes::Type		VideoMode	Scanner operation mode (video/snapshot)
→	inImageType	ZebraScanEnginesImageTypes::Type		BmpFile	Image format for the snapshot mode
←	outImage	Image&			Captured frame

Remarks

This filter is intended to cooperate with a scanner using its vendor SDK. To be able to connect to a scanner, it is required to install Zebra Scanner SDK software with Zebra CoreScanner Driver.

Zebra Scanner SDK can be downloaded from the following website: https://www.zebra.com/us/en/support-downloads/software/developer-tools/scanner-sdk-for-windows.html (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Zebra Scanner SDK version for Aurora Vision Studio usage is **3.06.0024**.

Scanner identification

When there is only one scanner connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available scanner will be found and connected.

inDeviceID field can be used to pick one of multiple scanners connected to the computer. DeviceID can be set to:

- **ID number** – can be obtained from Scanner SDK Sample Application which is installed during the Zebra Scanner SDK installation. The ID is the number in the column **"#"** under "Connected Scanners".

Automatic trigger

inAutoTriggerPeriod field can be used to specify the period of the automatic trigger when **inAutoTrigger** is set to true. By default, when this field is set to Auto, the triggers are generated with a 1-second period. Be careful when choosing values for the period, as values that are too small can destabilize the device and not perform as expected.

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

Also in AVL Lite

ZebraScanEngines_GrabImage_WithTimeout

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Captures a frame using a Zebra scanner.

Syntax

```
bool avl::ZebraScanEngines_GrabImage_WithTimeout
(
 ZebraScanEngines_State& ioState,
 int inTimeout,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 bool inAutoTrigger,
 atl::Optional<int> inAutoTriggerPeriod,
 avl::ZebraScanEnginesOperationModes::Type inOperationMode,
 avl::ZebraScanEnginesImageTypes::Type inImageType,
 atl::Conditional<avl::Image>& outImage
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
→	inTimeout	int	1 – ∞	100	Maximum time to wait for a frame in milliseconds
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
→	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
→	inAutoTrigger	bool		True	Enables or disables auto triggering
→	inAutoTriggerPeriod	Optional<int>	10 – ∞	NIL	Period of automatic triggers (in ms)
→	inOperationMode	ZebraScanEnginesOperationModes::Type		VideoMode	Scanner operation mode (video/snapshot)
→	inImageType	ZebraScanEnginesImageTypes::Type		BmpFile	Image format for the snapshot mode
←	outImage	Conditional<Image>&			Captured frame

Remarks

This filter is intended to cooperate with a scanner using its vendor SDK. To be able to connect to a scanner, it is required to install Zebra Scanner SDK software with Zebra CoreScanner Driver.

Zebra Scanner SDK can be downloaded from the following website: https://www.zebra.com/us/en/support-downloads/software/developer-tools/scanner-sdk-for-windows.html (registration may be required).

ZebraScanEngines_ListScanners

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Lists available Zebra scanners.

Syntax

```
void avl::ZebraScanEngines_ListScanners
(
 ZebraScanEngines_State& ioState,
 atl::Array<avl::ZebraScanEnginesDeviceInfo>& outScannerList
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraScanEngines_State&		Object used to maintain state of the function.
	outScannerList	Array<ZebraScanEnginesDeviceInfo>&		List of connected scanners

Remarks

During frequent requests for a list of devices, it is possible to break the connection with the polling device. It is not recommended to use this filter in a production environment. It is for debugging only.

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_ScanBarcode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Scans a barcode using a Zebra scanner.

Syntax

```
bool avl::ZebraScanEngines_ScanBarcode
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::ZebraScanEnginesBarcodeDataTypes::Type& outBarcodeType,
 atl::String& outBarcodeDecoded,
 avl::ByteBuffer& outRawData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
←	outBarcodeType	ZebraScanEnginesBarcodeDataTypes::Type&			Barcode type
←	outBarcodeDecoded	String&			Barcode data
←	outRawData	ByteBuffer&			Raw barcode data

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_ScanBarcode_WithTimeout

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Scans a barcode using a Zebra scanner.

Syntax

```
bool avl::ZebraScanEngines_ScanBarcode_WithTimeout
(
 ZebraScanEngines_State& ioState,
 int inTimeout,
 atl::Optional<int> inDeviceID,
 atl::Conditional<avl::ZebraScanEnginesBarcodeDataTypes::Type>& outBarcodeType,
 atl::Conditional<atl::String>& outBarcodeDecoded,
 atl::Conditional<avl::ByteBuffer>& outRawData
)
```

Parameters

	Name	Type	Range	Default	Description
↔	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
→	inTimeout	int	1 – ∞	100	Maximum time to wait for a barcode in milliseconds
→	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
←	outBarcodeType	Conditional<ZebraScanEnginesBarcodeDataTypes::Type>&			Barcode type
←	outBarcodeDecoded	Conditional<String>&			Barcode data
←	outRawData	Conditional<ByteBuffer>&			Raw barcode data

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_SetParameter

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Set parameter of a specified scanner temporarily or persistently.

Syntax

```
void avl::ZebraScanEngines_SetParameter
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 int inParameterID,
 const atl::String& inParameterType,
 atl::Optional<atl::String>& inParameterValue,
 bool inIsPersistent
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inParameterID	int	0 – ∞		Attribute number
	inParameterType	const String&			Attribute type
	inParameterValue	Optional<String>&		NIL	Attribute value
	inIsPersistent	bool		False	Whether to make the change persistent

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_StartAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Initializes and starts image acquisition in a scanner.

Syntax

```
void avl::ZebraScanEngines_StartAcquisition
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 int inInputQueueSize,
 bool inAutoTrigger,
 atl::Optional<int> inAutoTriggerPeriod,
 avl::ZebraScanEnginesOperationModes::Type inOperationMode,
 avl::ZebraScanEnginesImageTypes::Type inImageType
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>		NIL	Device identifying number
	inInputQueueSize	int	1 – 200	4	Capacity of output frames queue
	inAutoTrigger	bool		True	Enables or disables auto triggering
	inAutoTriggerPeriod	Optional<int>	10 – ∞	NIL	Period of automatic triggers (in ms)
	inOperationMode	ZebraScanEnginesOperationModes::Type		VideoMode	Scanner operation mode (video/snapshot)
	inImageType	ZebraScanEnginesImageTypes::Type		BmpFile	Image format for the snapshot mode

Remarks

This filter is intended for establishing connection with a Zebra scanner device using Zebra Scanner SDK interface, to initialize image streaming. It is only needed when explicit image acquisition start is required in the initial phase of a program.

The use of this filter is not obligatory. ZebraScanEngines_GrabImage or ZebraScanEngines_GrabImage_WithTimeout] filters will initialize and start image acquisition upon their first invoke.

This filter has no effect when invoked for the second time and when invoked after image grabbing filters.

This filter is intended to cooperate with a scanner using its vendor SDK. To be able to connect to a scanner, it is required to install Zebra Scanner SDK software with Zebra CoreScanner Driver.

Zebra Scanner SDK can be downloaded from the following website: https://www.zebra.com/us/en/support-downloads/software/developer-tools/scanner-sdk-for-windows.html (registration may be required).

Add DLL path to system environment variable may be required.

Recommended Zebra Scanner SDK version for Aurora Vision Studio usage is **3.06.0024**.

Scanner identification

When there is only one scanner connected to a computer, field **inDeviceID** can be set to Auto. In this case, first available scanner will be found and connected.

inDeviceID field can be used to pick one of multiple scanners connected to the computer. DeviceID can be set to:

- **ID number** – can be obtained from Scanner SDK Sample Application which is installed during the Zebra Scanner SDK installation. The ID is the number in the column **"#"** under "Connected Scanners".

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- ZebraScanEngines_GrabImage_WithTimeout – Captures a frame using a Zebra scanner.

Also in **AVL Lite**

ZebraScanEngines_StopAcquisition

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Stops image acquisition in a scanner.

Syntax

```
void avl::ZebraScanEngines_StopAcquisition
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID
)
```

Parameters

	Name	Type	Default	Description
	ioState	ZebraScanEngines_State&		Object used to maintain state of the function.
	inDeviceID	Optional<int>	NIL	Device identifying number

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

ZebraScanEngines_SwitchHostMode

Also in AVL Lite

Header: ThirdPartySdk.h
Namespace: avl
Module: ThirdParty

Switch host mode of a specified scanner.

Syntax

```
void avl::ZebraScanEngines_SwitchHostMode
(
 ZebraScanEngines_State& ioState,
 atl::Optional<int> inDeviceID,
 avl::ZebraScanEnginesHostModes::Type inHostMode,
 bool inSilentSwitch,
 bool inIsPermanentChange
)
```

Parameters

	Name	Type	Range	Default	Description
	ioState	ZebraScanEngines_State&			Object used to maintain state of the function.
	inDeviceID	Optional<int>	1 – ∞	NIL	Device identifying number
	inHostMode	ZebraScanEnginesHostModes::Type		USB_SNAPI_with_Imaging	Scanner USB host mode
	inSilentSwitch	bool			Whether to suppress the typical device reboot beeps
	inIsPermanentChange	bool			Whether to keep the targeted host mode as the permanent host mode of the device

Multithreaded environment

This function is not guaranteed to be thread-safe. When used in multithreaded environment, it has to be manually synchronized.

- GigEVision_OpenDevice
- GigEVision_OpenSystemConfiguration
- GigEVision_ReceiveImage
- GigEVision_StartAcquisition
- GigEVision_StopAcquisition
- GigEVision_TryReceiveImage

GigEVision_CloseHandle

Header: Genicam.h
Namespace: avl
Module: Genicam

Closes a handle opened in GigE Vision subsystem.

Syntax

```
void avl::GigEVision_CloseHandle
(
 GigEHandle inHandle
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GigEHandle		

GigEVision_FindDevices

Header: Genicam.h
Namespace: avl
Module: Genicam

This function performs enumeration of network devices and returns a list of present device descriptors.

Syntax

```
void avl::GigEVision_FindDevices
(
 int inTime,
 int inMaxDevices,
 atl::Array< GigEVision_DeviceDescriptor >& outDevices
)
```

Parameters

	Name	Type	Default	Description
→	inTime	int		Time, in milliseconds, that the function will wait for device response. This is the time that the function will block execution before return.
→	inMaxDevices	int	0	Maximum number of devices to enumerate or 0 to return all devices.
←	outDevices	Array< GigEVision_DeviceDescriptor >&		Returns a list with device descriptors. Array passed as buffer is cleared before search and appended with descriptors.

Description

This function broadcasts a single discovery request in the local network and waits for a specified amount of time for devices' responses. All responses are converted into device descriptors and appended into output array.

Devices that cause errors related to their single response are ignored in the output list, only network related errors corresponding to the discovery broadcasts cause the function to fail with exception.

A single device is identified by GigEVision_DeviceDescriptor structure.

Exceptions

This function will throw an exception in the following situation:

- Unexpected network related error.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_FlushInputQueue

Header: Genicam.h
Namespace: avl
Module: Genicam

Discards remaining queued image frames and video stream data from network buffers.

Syntax

```
void avl::GigEVision_FlushInputQueue
(
 GigEHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GigEHandle		Handle of an opened device which streaming queue should be cleared.

Description

Flushing input queue means, that all frames that have been received from device and that have not been retrieved yet by the application, will be discarded and lost (including a partially filled frame and buffered network packets of next frames).

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_GetAcquisitionActive

Header: Genicam.h
Namespace: avl
Module: Genicam

Checks if specified device is currently streaming video.

Syntax

```
bool avl::GigEVision_GetAcquisitionActive
(
 GigEHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GigEHandle		Handle of an opened device that will be checked for streaming.

Description

Return Value

true, when device connection is active and device is streaming video, false otherwise.

Exceptions

This function will throw an exception in the following situation:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_GetDeviceConnectionOpened

Header: Genicam.h
Namespace: avl
Module: Genicam

Checks if connection with specified device is still active.

Syntax

```
bool avl::GigEVision_GetDeviceConnectionOpened
(
 GigEHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GigEHandle		Handle of an opened device that will be checked.

Description

This function will return false after connection with device has been lost.

This function is indicative only. There is no guarantee that subsequent operations will not fail even if this function returns true. Broken connection can be detected after significant delay or during execution of other operations.

Exceptions

This function will throw an exception in the following situation:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_GetPixelFormats

Header: Genicam.h
Namespace: avl
Module: Genicam

Retrieves a list of available pixel formats supported by opened device.

Syntax

```
void avl::GigEVision_GetPixelFormats
(
 GigEHandle inDeviceHandle,
 atl::Array< atl::String >& outFormats
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GigEHandle		Handle of an opened device.
←	outFormats	Array< String >&		Array that will return a list of format strings.

Description

This function will access GenICam "PixelFormat" standard enumeration parameter and read its entries. Only entries marked as implemented and available will be present in the returned list. The list will contain names of PixelFormat enumeration entries (not display names).

One of the format names returned by this function can be passed to GigEVision_StartAcquisition function.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Connection with device is lost.
- Device is not a video transmitter.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_GetStreamingStatistics

Header: Genicam.h
Namespace: avl
Module: Genicam

Retrieves basic statistics of video streaming out of a GigEVision device.

Syntax

```
void avl::GigEVision_GetStreamingStatistics
(
 GigEHandle inDeviceHandle,
 bool inReset,
 GigEVision_StreamingStatistics& outStatistics
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GigEHandle		Handle of an opened device that is streaming video.
→	inReset	bool		True to reset internal device statistics after read.
←	outStatistics	GigEVision_StreamingStatistics&		

Description

This function is intended to help with diagnosing video streaming and network transfer issues, and it allows to read basic streaming statistic counters from the acquisition engine.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_OpenDevice

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens a handle to a GigE Vision device.

Syntax

```
GigEHandle avl::GigEVision_OpenDevice
(
 const atl::String& inDeviceAddress
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceAddress	const String&		Textual address that identifies a device in the network.

Description

When specified device is already opened upon function call, a new handle to the same device connection is returned.

When the device is opened for the first time, the library will attempt to establish a network connection, set up its state, load and interpret GenICam description.

For every call to GigEVision_OpenDevice a GigEVision_CloseHandle function must be called on returned handle.

When the device is opened, a new thread is started in the process. It controls and sustains the connection with the device and will be responsible for receiving stream packets.

Device address can be specified in one of following forms:

- **IP Address** – standard IPv4 address, for example "192.168.0.100". In this option the library will immediately attempt to establish a connection with specified address.
- **MAC Address** – 6 hexadecimals numbers representing the device network interface hardware address, for example "11:22:33:aa:bb:cc". In this option the library will first attempt to find the specified device in the network to retrieve its current IP address. This option can be used when the device is configured for automatic IP setup.
- **Serial number** – identified by "SN:" prefix, for example "SN:123456789". This option is similar to a MAC Address but uses a serial number to find the device in the network. Please note that not all GigE Vision devices support serial number identification.

Return Value

Handle to an open device. This handle can be used with other GigE Vision functions to control device state and image streaming, as well as with GenApi functions to access device GenApi parameters set.

Exceptions

This function will throw an exception in the following situations:

- Device address string has an invalid format.
- Device with specified address cannot be found in the network.
- Device connection operation failed.
- Device initial setup failed.
- GenICam device description xml file could not be loaded.
- Other GenICam or network related error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_OpenSystemConfiguration

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens configuration node set of GigE Vision application transport layer.

Syntax

```
GigEHandle avl::GigEVision_OpenSystemConfiguration()
```

Description

This function allows to access library global configuration parameters (connection configuration on application side) for GigE Vision subsystem. The function returns a handle to parameters' set, that can be accessed with GenApi functions. Every handle returned by this function must be closed with GigEVision_CloseHandle function.

Configuration changes take effects only for devices opened afterwards (so configuration of currently opened and active devices is not changed).

Configuration set contains the following parameters:

Name (id)	Type	Description
GevAppTLPacketResendsCount	Integer	Maximum number of command resends to device on control channel, when command acknowledgment is not received. After specified number of attempts current operation is terminated with "no response" error. Range: 1...10 Default: 3
GevAppTLAckTimeout	Integer	Time in milliseconds that the application will wait for command acknowledgment from the device when communicating on control channel. After timeout elapses with no acknowledgment the application will assume that command message was lost. Range: 100...2000 Default: 300
GevAppTLHertbeatTimeout	Integer	Value in milliseconds of maximum allowed time without communication on control channel. After this time the application will send a so called heartbeat signal to the device. When the device is left without a heartbeat signal or the application did not receive a heartbeat acknowledgment, connection is assumed to be lost. Range: 500...20000 Default: 1000
GevAppTLDefaultFrameWaitTimeout	Integer	Value in milliseconds of wait timeout for GigEVision_ReceiveImage function. After this time when no new frame is available function will control connection state and raise an appropriate exception. Range: 500...30000 Default: 4000
GevAppTLConnectionOpeningAttemptsCount	Integer	Number of connection attempts for opening device. When connection related errors occur during device finding or device connection opening, library will not raise an exception but will attempt to open the connection again. This is the maximum allowed number of such attempts. Range: 1...30 Default: 3
GevAppTLDisablePacketSizeNegotiation	Boolean	When set to false, allows the library to automatically negotiate packet size with a device. Video streaming performance is higher when packet size is bigger, that is why the library will try to find the maximum allowed size for the current network configuration, but this negotiation take some time upon connection opening. When network configuration is complicated, maximum allowed packet size can change dynamically which cannot be noticed by the application. In such situation packet negotiation should be disabled. Default: False
GevAppTLEnableConstantPacketSize	Boolean	When packet size negotiation is disabled, the packet size may be left unchanged in device settings or set by library to a constant value on every connection. Set this parameter to False to left packet size unchanged, or to True to use packet size from GevAppTLConstantPacketSize parameter. Requires: GevAppTLDisablePacketSizeNegotiation=True Default: False

GevAppTLConstantPacketSize	Integer	When packet size negotiation is disabled and constant packet size is enabled this parameter specifies network packet size in bytes to use on video stream connection. Larger packet sizes are better for performance but are not always supported by network infrastructure. Requires: GevAppTLEnableConstantPacketSize=True Range: 100...100000
GevAppTLSocketBufferSize	Integer	Specifies the stream channel network socket input buffer size in kilobytes. Range: 2048kB...262144kB (2MB...256MB)
GevAppTLConnectInExclusiveMode	Boolean	Determines privilege mode of connection with device. When set to True enables Exclusive mode connection. In Exclusive mode only one application can be connected with device and only one application can read device state. When set to False disables exclusive mode and connects in Control mode. In Control mode other applications are permitted to monitor state of device. Default: True
GevAppTLUseMessageChannel	Boolean	When set to True, enables driver to open message channel in device. When device supports asynchronous events a message channel is used to deliver notifications with their data. Disabling message channel will disable event notifications. When device is not supporting message channel its opening will fail and driver will continue without message channel. Default: True
GevAppTLIgnoreGevImageTrailer	Boolean	When set to True, causes that image format parameters sent in image trailer packet are ignored and only image data leader participates in image format. Default: False
GevAppTLEnablePacketsRetransmission	Boolean	Enables stream missing packets detection and retransmission request (when supported by the device). Default: True
GevAppTLResetBlockIdOnAcquisitionStart	Boolean	When enabled resets stream channels BlockId counter on every acquisition start (used to resolve some compatibility issues with cameras). Default: False
GevAppTLEnableGenApiCache	Boolean	When set to True, enables GenApi cache. GenApi cache will store values read from device in the local computer memory to limit network traffic. Not all parameters can be cached. Cache performance depends on individual device and accessed parameters. Disabling cache will cause driver to read all parameters from device every time, including meta data like value ranges and access mode. Disabling cache will decrease speed of GenApi parameter operations. Default: True
GevAppTLRequest64BitBlockIdMode	Boolean	For GigEVision 2.0 compatible devices enables requesting the device to use 64bit Block ID mode. Default: True
GevAppTLActivateDevicePTP	Boolean	When set activates Precision Time Protocol in the device (when supported by the device). Default: False
GevAppTLAllowLocalXmlOverride	Boolean	When set to True allows to load GenICam xml file from local file system (when found) instead of location specified by device. Default: True

Examples

This example shows how to set up the library for forcing video stream packet size in a device equal to 8000 bytes.

```
avl::GigEHandle hSet = avl::GigEVision_OpenSystemConfiguration();

avl::GenApi_SetBooleanParam(hSet, "GevAppTLDisablePacketSizeNegotiation", true);
avl::GenApi_SetBooleanParam(hSet, "GevAppTLEnableConstantPacketSize", true);
avl::GenApi_SetIntegerParam(hSet, "GevAppTLConstantPacketSize", 8000);

avl::GigEVision_CloseHandle(hSet);
```

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_ReceiveImage

Header: Genicam.h
Namespace: avl
Module: Genicam

Receives next frame from video stream.

Syntax

```
void avl::GigEVision_ReceiveImage
(
 GigEHandle inDeviceHandle,
 avl::Image& outImage,
 atl::Optional<atl::uint64&> outFrameId = atl::NIL,
 atl::Optional<atl::uint64&> outTimestamp = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GigEHandle		Handle of an opened device that is streaming video.
←	outImage	Image&		Image buffer that will receive a new frame.
←	outFrameId	Optional<uint64&>	NIL	Frame block Id set by device
←	outTimestamp	Optional<uint64&>	NIL	Frame capture timestamp set by device (when supported)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outFrameId**, **outTimestamp**.

Read more about Optional Outputs.

Description

This function will return the next available frame from incoming buffer. When input buffer is empty the function will block execution and wait for the next frame to be completed.

The function returns only complete and valid frames, when a frame is corrupted and it cannot be fixed, it is automatically discarded by the library.

A frame is converted from the device stream pixel format to the best suitable format of avl::Image. Automatic conversion includes:

- Conversion from Bayer color mosaic to RGB.
- Conversion of YUV to RGB.
- Ordering of RGB/aRGB channels.
- Unpacking 10, 12 or 14 bpp into 16 bpp images.

Returned image can contain 1, 3 or 4 channels with sint8, uint8 or uint16 pixel type.

outFrameId parameter is optional (can be set to Nil, when not used or given a reference to an output variable). This parameter returns a number identifying current frame in video sequence. This number is generated by device and incremented by one at the beginning of transmission of every frame block. The valid range of this id, for GigEVision compliant devices, is 1...65535 (starting at 1 and incrementing sequentially up to 65535, then wrapping back to 1). This value can be used to control correctness of received image sequence and detection of lost frames. Please note that this method can be used only to detect frames that was transmitted by device but lost before application could process them. This method cannot be used when lost image was not transmitted by device (e.g. when device missed trigger signal).

outTimestamp parameter is optional (can be set to Nil, when not used or given a reference to an output variable). This parameter returns a timestamp of current frame that was marked by the device at point of grabbing the image. Support of this parameter by the device is optional and for some devices this output can be not effective. Frequency of the timer used for this timestamp is device dependent. Refer to device documentation for details about timestamp timer. Usually a frequency of this timer can be retrieved using a GevTimestampTickFrequency parameter available in device parameters tree. Value of this output will wrap around in range from 0 to $2^{31}-1$.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Device is not streaming video.
- Timeout occurred when waiting for next complete frame.
- Device sends image in pixel format that cannot be converted.
- Device streams in a mode that does not transport images or the library is unable to read the image from stream.
- Device connection is lost and cannot be restored.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GigEVision_OpenDevice – Opens a handle to a GigE Vision device.
- GigEVision_StartAcquisition – Initializes and starts image acquisition in a device.

GigEVision_StartAcquisition

Header: Genicam.h
Namespace: avl
Module: Genicam

Initializes and starts image acquisition in a device.

Applications: Typically used for initialization of multi-camera systems.

Syntax

```
void avl::GigEVision_StartAcquisition
(
 GigEHandle inDeviceHandle,
 const atl::String& inPixelFormat,
 int inInputQueueSize = 1
)
```

Parameters

	Name	Type	Range	Default	Description
→	inDeviceHandle	GigEHandle			Handle of an opened device that should start acquisition.
→	inPixelFormat	const String&			Pixel format name in GenICam naming convention that will be configured as device stream PixelFormat parameter.
→	inInputQueueSize	int	1 – 400	1	Capacity of queue of input frames.

Description

This function sets up the device to stream with specified pixel format, prepares internal buffers for stream and starts acquisition in device by executing StartAcquisition command.

Set **inPixelFormat** parameter to empty string to leave current device pixel format unchanged.

Use GigEVision_GetPixelFormats function to determine device supported pixel formats and their names.

Do not access GenICam StartAcquisition and StopAcquisition commands directly, always use GigEVision_StartAcquisition and GigEVision_StopAcquisition functions so that the library state can stay in sync with device state.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Device is not a video transmitter.
- Specified pixel format name is not supported by device.
- Device connection is lost.
- Other unexpected GenICam error or device setup error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GigEVision_StopAcquisition – Stops image acquisition in a device.

GigEVision_StopAcquisition

Header: Genicam.h
Namespace: avl
Module: Genicam

Stops image acquisition in a device.

Syntax

```
void avl::GigEVision_StopAcquisition
(
 GigEHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GigEHandle		Handle of an opened device that should stop acquisition

Description

This function stops acquisition started by GigEVision_StartAcquisition by executing GenICam StopAcquisition command. The function will not fail when a device is not streaming video.

Do not access GenICam StartAcquisition and StopAcquisition commands directly, always use GigEVision_StartAcquisition and GigEVision_StopAcquisition function so that the library state can stay in sync with device state.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Connection is lost.
- Other unexpected GenICam or network error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GigEVision_TryReceiveImage

Header: Genicam.h
Namespace: avl
Module: Genicam

Receives next frame from video stream.

Syntax

```
bool avl::GigEVision_TryReceiveImage
(
 GigEHandle inDeviceHandle,
 int inTimeout,
 avl::Image& outImage,
 atl::Optional<atl::uint64&> outFrameId = atl::NIL,
 atl::Optional<atl::uint64&> outTimestamp = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GigEHandle		Handle of an opened device that is streaming video.
→	inTimeout	int		Maximum time in milliseconds that the function is allowed to wait for the next complete frame. This parameter overrides the global frame timeout configuration.
←	outImage	Image&		Image buffer that will receive a new frame.
←	outFrameId	Optional<uint64&>	NIL	Frame block Id set by device
←	outTimestamp	Optional<uint64&>	NIL	Frame capture timestamp set by device (when supported)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outFrameId**, **outTimestamp**.

Read more about Optional Outputs.

Description

This function is a close equivalent of GigEVision_ReceiveImage, that gives additional control over frame timeout situation.

See GigEVision_ReceiveImage definition for more information.

Return Value

true when new frame is successfully received and stored into **outImage**, false when timeout occurs or device is not streaming.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Connection with device is lost.
- Device sends image in pixel format that cannot be converted.
- Device streams in a mode that does not transport images or the library is unable to read the image from stream.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_ExecuteCommand

Header: Genicam.h
Namespace: avl
Module: Genicam

Executes named command parameter using GenICam ICommand interface.

Syntax

```
void avl::GenApi_ExecuteCommand
(
 GenApiHandle inHandle,
 const char* inCommandName,
 bool inVerifyAccess = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inCommandName	const char*		Textual name of the command parameter that should be executed in GenICam naming convention or device specific name. Command name is case sensitive.
➡	inVerifyAccess	bool	true	True to verify parameter access.

Description

This function accesses a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

This function does not control parameter state or wait for command completion. Accessing parameter in an improper device state may silently fail, results on the device side are undefined.

Refer to device documentation or use the Device Manager to find the proper command parameter name. Do not use commands to start or stop image acquisition, use dedicated library's APIs instead.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with the specified name.
- Named parameter does not provide the ICommand interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetBooleanParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter value using GenICam IBoolean interface.

Syntax

```
bool avl::GenApi_GetBooleanParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inVerifyAccess	bool	true	True to verify parameter access.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IBoolean interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetCategoryDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named category description from GenICam interface.

Syntax

```
void avl::GenApi_GetCategoryDescriptor
(
 GenApiHandle inHandle,
 const char* inCategoryName,
 GenApi_CategoryDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inCategoryName	const char*		Textual name of the category that should be accessed in GenICam naming convention or device specific name. Category name is case sensitive.
←	outDescriptor	GenApi_CategoryDescriptor&		

Description

This function accesses the configuration of a device or a software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle).

Categories are special types of GenApi nodes not associated with a parameter value. Instead, a category contains a list of other parameters or categories, forming a tree structure of top level parameters. Categories' trees are usable for creating user interface. The main category of every GenApi set is named "Root".

This function can be used to obtain description of named Category. Information is returned using GenApi_CategoryDescriptor structure.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a category with specified name.
- Named parameter does not provide the ICategory interface.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetEnumDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named enum parameter description from GenICam IEnumeration interface.

Syntax

```
void avl::GenApi_GetEnumDescriptor
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inAvailableEntriesOnly,
 GenApi_EnumDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
→	inAvailableEntriesOnly	bool		True to include in returned description only implemented and available enumeration entries.
←	outDescriptor	GenApi_EnumDescriptor&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

This function can be used to obtain the description of named Enumeration parameter with the list of enumeration entries. The information is returned using GenApi_EnumDescriptor structure.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IEnumeration interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetEnumParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter value using GenICam IEnumeration interface.

Syntax

```
void avl::GenApi_GetEnumParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
→	inVerifyAccess	bool		True to verify parameter access.
←	outValue	String&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

The returned value is a textual id of the currently selected enumeration entry.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IEnumeration interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetFloatDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named float parameter attributes from GenICam IFloat interface.

Syntax

```
void avl::GenApi_GetFloatDescriptor
(
 GenApiHandle inHandle,
 const char* inParameterName,
 GenApi_FloatDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
←	outDescriptor	GenApi_FloatDescriptor&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

This function can be used to obtain additional information of named Float parameter, like its range. The information is returned using GenApi_FloatDescriptor structure.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IFloat interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetFloatParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter value using GenICam IFloat interface.

Syntax

```
double avl::GenApi_GetFloatParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inVerifyAccess	bool	true	True to verify parameter access.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IFloat interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetIntegerDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named integer parameter attributes from GenICam IInteger interface.

Syntax

```
void avl::GenApi_GetIntegerDescriptor
(
 GenApiHandle inHandle,
 const char* inParameterName,
 GenApi_IntegerDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
←	outDescriptor	GenApi_IntegerDescriptor&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

This function can be used to obtain additional information of named Integer parameter, like its range and allowed increment. The information is returned using GenApi_IntegerDescriptor structure.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IInteger interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetIntegerParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter value using GenICam IInteger interface.

Syntax

```
atl::sint64 avl::GenApi_GetIntegerParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess = true
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
→	inVerifyAccess	bool	true	True to verify parameter access.

Description

This function accesses the configuration of a device or software module using GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to device documentation or use device manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IInteger interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetParamDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter description and attributes from GenICam interface.

Syntax

```
void avl::GenApi_GetParamDescriptor
(
 GenApiHandle inHandle,
 const char* inParameterName,
 GenApi_ParameterDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
←	outDescriptor	GenApi_ParameterDescriptor&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

This function can be used to obtain additional information, meta data and the state of a GenICam parameter. The information is returned using GenApi_ParameterDescriptor structure.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetParamExists

Header: Genicam.h
Namespace: avl
Module: Genicam

Checks if parameter, category or command with specified name exists in GenApi set.

Syntax

```
bool avl::GenApi_GetParamExists
(
 GenApiHandle inHandle,
 const char* inParameterName
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter, category or command that should be checked in GenICam naming convention or device specific name. Name is case sensitive.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Return value

False, when GenApi description does not provide a parameter or command with specified name. True, when any kind of parameter or command exists in the referenced GenApi description, regardless of its interface, implementation state or availability (use GenApi_GetParamDescriptor function to retrieve more information about existing parameter).

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_GetRegisterDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named register parameter description from GenICam IRegister interface.

Syntax

```
void avl::GenApi_GetRegisterDescriptor
(
 GenApiHandle inHandle,
 const char* inParameterName,
 GenApi_RegisterDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
←	outDescriptor	GenApi_RegisterDescriptor&		

GenApi_GetStringParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads named parameter value using GenICam IInteger interface.

Syntax

```
void avl::GenApi_GetStringParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess,
 atl::String& outValue
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
→	inVerifyAccess	bool		True to verify parameter access.
←	outValue	String&		

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IString interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_ReadRegisterData

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads raw binary data from the objects memory using the IRegister interface.

Syntax

```
void avl::GenApi_ReadRegisterData
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inVerifyAccess,
 atl::sint64 inLength,
 void* ioBuffer
)
```

Parameters

	Name	Type	Default	Description
→	inHandle	GenApiHandle		Handle to object providing GenApi interface.
→	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
→	inVerifyAccess	bool		True to verify parameter access.
→	inLength	sint64		Size of the data to read.
↔	ioBuffer	void*		Buffer for the read data to be placed in (allocated with at least inLength bytes).

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Application must allocate a buffer for the data and provide its pointer on the **ioBuffer** parameter. **inLength** specifies the amount of data (in bytes) to read from the register (starting at its beginning). GenApi_GetRegisterDescriptor can be used to determine the register size.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to the device documentation or use Device Manager to find a proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IRegister interface.
- Null pointer is provided on the **ioBuffer** parameter.
- Requested data read size is larger than the range of the register.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Null pointer on ioBuffer parameter.

GenApi_SetBooleanParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes named parameter value using GenICam IBoolean interface.

Syntax

```
void avl::GenApi_SetBooleanParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 bool inValue,
 bool inVerify = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inValue	bool		New value that should be written to parameter.
➡	inVerify	bool	true	True to verify parameter access.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerify** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the results on device side are undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide parameter with specified name.
- Named parameter does not provide the IBoolean interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_SetEnumParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes named parameter value using GenICam IEnumeration interface.

Syntax

```
void avl::GenApi_SetEnumParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 const char* inValue,
 bool inVerify = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inValue	const char*		New enumeration entry id that should be written to parameter.
➡	inVerify	bool	true	True to verify parameter access and value range and alignment.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

The new value must be specified as a textual id of one of enumeration entries.

Set **inVerify** argument to true to check new value range, increment and parameter state. When this argument is set to false writing invalid value or accessing parameter in an improper device state will silently fail, the results on device side are undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IEnumeration interface.
- Enumeration value does not exist in parameter.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_SetFloatParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes named parameter value using GenICam IFloat interface.

Syntax

```
void avl::GenApi_SetFloatParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 double inValue,
 bool inVerify = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inValue	double		New value that should be written to parameter.
➡	inVerify	bool	true	True to verify parameter access and value range.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerify** argument to true to check new value range and parameter state. When this argument is set to false writing invalid value or accessing parameter in an improper device state will silently fail, the results on device side are undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IFloat interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_SetIntegerParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes named parameter value using GenICam IInteger interface.

Syntax

```
void avl::GenApi_SetIntegerParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 atl::sint64 inValue,
 bool inVerify = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inValue	sint64		New value that should be written to parameter.
➡	inVerify	bool	true	True to verify parameter access and value range and alignment.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerify** argument to true to check new value range, increment and parameter state. When this argument is set to false writing invalid value or accessing parameter in an improper device state will silently fail, the results on device side are undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid or does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IInteger interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_SetStringParam

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes named parameter value using GenICam IString interface.

Syntax

```
void avl::GenApi_SetStringParam
(
 GenApiHandle inHandle,
 const char* inParameterName,
 const char* inValue,
 bool inVerify = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inValue	const char*		New value that should be written to parameter.
➡	inVerify	bool	true	True to verify parameter access and value range and alignment.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with device.

Set **inVerify** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the results on device side are undefined.

Refer to device documentation or use the Device Manager to find proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IString interface.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenApi_WriteRegisterData

Header: Genicam.h
Namespace: avl
Module: Genicam

Writes raw binary data into the objects memory using the IRegister interface.

Syntax

```
void avl::GenApi_WriteRegisterData
(
 GenApiHandle inHandle,
 const char* inParameterName,
 const void* inData,
 atl::sint64 inLength,
 bool inVerifyAccess = true
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenApiHandle		Handle to object providing GenApi interface.
➡	inParameterName	const char*		Textual name of the parameter that should be accessed in GenICam naming convention or device specific name. Parameter name is case sensitive.
➡	inData	const void*		Data that should be written to the parameter.
➡	inLength	sint64		Size of the data to be written.
➡	inVerifyAccess	bool	true	True to verify the parameter access.

Description

This function accesses the configuration of a device or software module using the GenICam GenApi interface. The actual GenApi interface is accessed through the handle of opened device or software module provided by other subsystem (like opened GigEVision device handle). A call to this function may result in time expensive (blocking) data exchange with the device.

Application provides a pointer on the data to write in the **inData** parameter, **inLength** specifies the amount (in bytes) of data to write (starting on the beginning of the register). GenApi_GetRegisterDescriptor can be used to determine the register size.

Set **inVerifyAccess** argument to true to check parameter state. When this argument is set to false accessing parameter in an improper device state may silently fail, the result is undefined.

Refer to the device documentation or use Device Manager to find a proper parameter name.

Exceptions

This function will throw an exception in the following situations:

- Object handle is invalid does not provide the GenApi interface.
- GenApi description does not provide a parameter with specified name.
- Named parameter does not provide the IRegister interface.
- Null pointer is provided on the **inData** parameter.
- Requested data write size is larger than the range of the register.
- Connection with device is lost.
- Other unexpected GenICam or connection error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Null pointer on inData parameter.

208. GenTL

Table of content:

- GenTL_Cleanup
- GenTL_CloseHandle

- GenTL_ReceiveImage
- GenTL_StartAcquisition
- GenTL_StopAcquisition
- GenTL_TryReceiveImage

GenTL_Cleanup

Header: Genicam.h
Namespace: avl
Module: Genicam

Closes all internally opened (cached) GenTL software modules not held any more by any opened handle.

Syntax

```
void avl::GenTL_Cleanup()
```

Description

When accessing structures of the GenTL system, software modules are opened to manage its entities (like library system module or interface module). GenTL subsystem can left some modules opened after operations on such structures (like enumeration or information access) to optimize subsequent function calls. Every open module uses some resources, both on GenTL provider side and on AVL side. You can use this function to force to close unused modules and to release unused resources.

Only unreferenced modules will be closed. A module is unreferenced, when the application does not hold any handle to it or its child modules.

GenTL subsystem never leaves a device module opened after its last handle has been closed. Also, the cleanup operation is performed after closing of any device.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_CloseHandle

Header: Genicam.h
Namespace: avl
Module: Genicam

Closes a handle opened in GenTL subsystem.

Syntax

```
void avl::GenTL_CloseHandle
(
 GenTLHandle inHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inHandle	GenTLHandle		

GenTL_EnumLibraries

Header: Genicam.h
Namespace: avl
Module: Genicam

Returns a list of loaded GenTL provider libraries available in the local system.

Syntax

```
void avl::GenTL_EnumLibraries
(
 atl::Array<atl::String>& outLibraryPaths
)
```

Parameters

	Name	Type	Default	Description
⬅	outLibraryPaths	Array<String>&		List of paths identifying libraries.

Description

At first use of any function, the GenTL subsystem will enumerate and attempt to load GenTL provider libraries registered in system. This function returns a list of successfully loaded GenTL provider libraries that can be used to communicate with devices. Single GenTL provider is identified by a path to its main module (a file with .cti extension).

To obtain additional information about provider library use GenTL_GetLibraryDescriptor function. To enumerate communication interfaces provided by the library use GenTL_EnumLibraryInterfaces function.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_EnumLibraryInterfaces

Header: Genicam.h
Namespace: avl
Module: Genicam

Returns a list of communication interfaces available in specified provider module library.

Syntax

```
void avl::GenTL_EnumLibraryInterfaces
(
 const atl::String& inLibraryPath,
 atl::Array<atl::String>& outInterfaceIds
)
```

Parameters

	Name	Type	Default	Description
➡	inLibraryPath	const String&		Path identifying provider library.
⬅	outInterfaceIds	Array<String>&		List of strings identifying interfaces.

Description

This function requests the GenTL provider to refresh a list of available communication interfaces. Parameter **outInterfaceIds** is than filled with unique textual ids of such interfaces.

To obtain additional information about an interface use GenTL_GetInterfaceDescriptor function.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GenTL_EnumLibraries – Returns a list of loaded GenTL provider libraries available in the local system.

GenTL_FindDevices

Header: Genicam.h
Namespace: avl
Module: Genicam

Performs enumeration of GenTL devices and returns a list of present device descriptors.

Syntax

```
void avl::GenTL_FindDevices
(
 atl::Optional<const atl::String&> inLibraryPath,
 atl::Optional<const atl::String&> inInterfaceId,
 atl::Optional<const atl::String&> inTLType,
 int inInterfaceScanTime,
 atl::Array<GenTL_DeviceDescriptor>& outDevices
)
```

Parameters

	Name	Type	Default	Description
→	inLibraryPath	Optional<const String&>	NIL	Path identifying provider library to limit enumeration to.
→	inInterfaceId	Optional<const String&>	NIL	String identifying communication interface to limit enumeration to.
→	inTLType	Optional<const String&>	NIL	Name of interface transport technology to limit enumeration to.
→	inInterfaceScanTime	int		Time limit, in milliseconds, that the function will wait for device response on each enumerated interface.
←	outDevices	Array<GenTL_DeviceDescriptor>&		Returns a list with device list descriptors.

Description

This function requests available GenTL provider libraries to perform enumeration of their interfaces and devices, and returns a unified list of all available devices. The function can perform a global enumeration (all available libraries and interfaces) as well as limited enumeration, where search can be narrowed to specific library, interface or transport technology.

inLibraryPath parameter can be set to a path identifying one of available GenTL libraries to limit enumeration to (only interfaces provided by this library will be checked). Setting this parameter will not force the GenTL subsystem to load the specified file. Requested library must be properly registered in local system and loaded upon GenTL subsystem initialization. Setting this parameter to atl::NIL causes that all available providers will be included in enumeration.

inInterfaceId parameter can be set to an internal identifier of provider interfaces to limit enumeration to (only these interfaces will be enumerated). When this argument is used, parameter **inLibraryPath** must be also specified. Setting this parameter to atl::NIL causes that all interfaces of applicable providers are enumerated.

inTLType parameter can be set to a name of Transport Technology Type. When this argument is used, only interfaces with equal transport technology type name are enumerated. When this parameter is set to atl::NIL enumeration is not restricted by interface type. This parameter cannot be used simultaneously with **inInterfaceId** (at least one of those arguments must be equal atl::NIL).

Any textual name of transport technology can be used for **inTLType** argument, including following standard type names:

- **"Custom"** – Custom technologies.
- **"GEV"** – GigE Vision technology.
- **"CL"** – Camera Link technology.
- **"IIDC"** – IIDC 1394 technology.
- **"UVC"** – USB video class devices.
- **"CXP"** – CoaXPress.
- **"CLHS"** – Camera Link HS.
- **"USB3"** – USB3 Vision Standard.
- **"Ethernet"** – Ethernet devices.
- **"PCI"** – PCI/PCIe devices.

(according to GenTL standard version 1.3)

inInterfaceScanTime argument specifies the time limit in milliseconds, that a single provider interface will be given to enumerate its devices. Every applicable interface will be given the same amount of time. Exact time that this function will block execution depends on number of applicable providers, number of applicable interfaces and on the way that provider performs enumeration.

All found devices (regardless of parent library or interface) are stored in a unified list returned by **outDevices** parameter. Single device is described by GenTL_DeviceDescriptor structure. Please note, that it is not impossible that single device is reachable by multiple interfaces or provider libraries. In such case, single device will be present in the list multiple times.

Exceptions

This function will throw an exception in the following situation:

- Optional arguments are used in improper way.
- Library specified by **inLibraryPath** or interface specified by **inInterfaceId** is not found.
- Other general GenTL error occurred.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

Errors

List of possible exceptions:

Error type	Description
DomainError	Parameter inLibraryPath is required when inInterfaceId is specified.
DomainError	Parameters inInterfaceId and inTLType cannot be used simultaneously.

GenTL_FlushInputQueue

Header: Genicam.h
Namespace: avl
Module: Genicam

Discards remaining received and queued image frames in device video stream.

Syntax

```
void avl::GenTL_FlushInputQueue
(
 GenTLHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GenTLHandle		Handle of an opened device which streaming queue should be cleared.

Description

Flushing input queue means that all frames that have been received from device and that have not been yet retrieved by the application, will be discarded and lost (including a partially filled frame).

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_GetAcquisitionActive

Header: Genicam.h
Namespace: avl
Module: Genicam

Checks if specified device is currently streaming video.

Syntax

```
bool avl::GenTL_GetAcquisitionActive
(
 GenTLHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GenTLHandle		Handle of an opened device that will be checked for streaming.

Description

Return Value

true, when device video streaming is currently active on application side (GenTL_StartAcquisition function has been successfully executed for specified handle), false otherwise.

Exceptions

This function will throw an exception in the following situation:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_GetInterfaceDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads description of GenTL provider communication interface.

Syntax

```
void avl::GenTL_GetInterfaceDescriptor
(
 const atl::String& inLibraryPath,
 const atl::String& inInterfaceId,
 GenTL_InterfaceDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inLibraryPath	const String&		Path identifying provider library.
→	inInterfaceId	const String&		String identifying communication interface.
←	outDescriptor	GenTL_InterfaceDescriptor&		Description retrieved from provider interface.

Description

This function accesses provider interface module and retrieves additional information from it. Data is returned using GenTL_InterfaceDescriptor structure.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GenTL_EnumLibraries – Returns a list of loaded GenTL provider libraries available in the local system.

GenTL_GetLibraryDescriptor

Header: Genicam.h
Namespace: avl
Module: Genicam

Reads description of GenTL provider library.

Syntax

```
void avl::GenTL_GetLibraryDescriptor
(
 const atl::String& inLibraryPath,
 GenTL_LibraryDescriptor& outDescriptor
)
```

Parameters

	Name	Type	Default	Description
→	inLibraryPath	const String&		Path identifying provider library.
←	outDescriptor	GenTL_LibraryDescriptor&		Description retrieved from provider library.

Description

This function accesses GenTL provider library system module and retrieves additional information from it. Data is returned using GenTL_LibraryDescriptor structure.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GenTL_EnumLibraries – Returns a list of loaded GenTL provider libraries available in the local system.

GenTL_GetPixelFormats

Header: Genicam.h
Namespace: avl
Module: Genicam

Retrieves a list of available pixel formats supported by opened device.

Syntax

```
void avl::GenTL_GetPixelFormats
(
 GenTLHandle inDeviceHandle,
 atl::Array< atl::String >& outFormats
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GenTLHandle		Handle of an opened device.
←	outFormats	Array< String >&		Array that will return a list of format strings.

Description

This function accesses GenICam "PixelFormat" standard enumeration parameter and reads its entries. Only entries marked as implemented and available will be present in the returned list. The list will contain names of PixelFormat enumeration entries (not display names).

One of the format names returned by this function can be passed to GenTL_StartAcquisition function.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Connection with device is lost.
- Device is not a video transmitter.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_GetStreamingStatistics

Header: Genicam.h
Namespace: avl
Module: Genicam

Retrieves basic statistics of video streaming out of GenICam device.

Syntax

```
void avl::GenTL_GetStreamingStatistics
(
 GenTLHandle inDeviceHandle,
 GenTL_StreamingStatistics& outStatistics
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GenTLHandle		Handle of an open device that is streaming video.
←	outStatistics	GenTL_StreamingStatistics&		

Description

This function is intended to help with diagnosing video streaming issues and it allows to read basic streaming statistic counters from the acquisition engine.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_OpenDevice

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens a handle to a device provided by GenTL library.

Syntax

```
GenTLHandle avl::GenTL_OpenDevice
(
 const atl::String& inLibraryPath,
 const atl::String& inInterfaceId,
 const atl::String& inDeviceId
)
```

Parameters

	Name	Type	Default	Description
➡	inLibraryPath	const String&		Path identifying provider library.
➡	inInterfaceId	const String&		String identifying communication interface through which device is accessed.
➡	inDeviceId	const String&		Unique identifier of device in provider communication interface.

Description

This function accesses a GenTL provider library modules' chain and device described by passed textual identifiers. When specified device is already opened upon function call, and a primary unique identifier of device is used, a new handle to the same device instance is returned.

inLibraryPath parameter identifies a provider library to use as a device driver. Although library is identified by its file path, this function will not load the specified file. Library must be properly registered in system and enumerated upon GenTL subsystem first use. **inInterfaceId** parameter specifies an internal provider library textual id of communication interface to use for connecting with device. Communication interface can correspond to a hardware interface or to a virtual category for the device class. Interfaces' organization depends on used GenTL provider library. **inDeviceId** parameter identifies the requested device in its communication interface. **inDeviceId** can be a unique device id defined by interface module or other alternative device textual address (when used GenTL provider library accepts one). When using alternative device address a single device cannot be opened multiple times using GenTL_OpenDevice function.

You can use GenTL_FindDevices function to quickly obtain library, interface and device identifying parameters. Alternatively you can use GenTL_EnumLibraries and GenTL_EnumLibraryInterfaces functions to discover available GenTL modules structure and pick required library and interface identifiers. When textual ids are not dynamically changed by provider at runtime it is also acceptable to statically define some identifiers of known library-interface-device chain.

For every call to GenTL_OpenDevice a GenTL_CloseHandle function must be called on returned handle.

Return Value

Handle to an opened device. This handle can be used with other GenTL functions to control device state and image streaming, as well as with GenApi functions to access device GenApi parameters set.

Exceptions

This function will throw an exception in the following situations:

- One of device addressing parameters is missing or has invalid format.
- Requested device cannot be found.
- Device connection operation failed.
- Device initial setup failed.
- GenICam device description xml file could not be loaded.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_OpenDeviceModuleSettings

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens configuration node set of GenTL device (a device module configuration) of application side transport layer.

Syntax

```
GenTLHandle avl::GenTL_OpenDeviceModuleSettings
(
 GenTLHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GenTLHandle		Handle of an opened device which application side module should be accessed.

Description

This function allows to access the connected device's software-side transport layer extended settings through GenAPI interface. The function takes a handle of the opened device (returned by GenTL_OpenDevice) and returns a new handle to its software module settings. You can use GenApi functions to access module settings.

For every call to GenTL_OpenDeviceModuleSettings GenTL_CloseHandle function must be called on returned handle. Device will be closed after all device and device module settings' handles have been closed.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- GenICam device description xml file of software module could not be loaded.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_OpenDeviceStreamModuleSettings

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens configuration node set of application side transport layer of GenTL device first data stream (a stream module configuration).

Syntax

```
GenTLHandle avl::GenTL_OpenDeviceStreamModuleSettings
(
 GenTLHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GenTLHandle		Handle of an opened device which application side stream module should be accessed.

Description

When working with a video transmitter device a separate software module is responsible for managing transmission on its video stream. This function allows to access the connected device's software-side video stream transport layer extended settings through GenAPI interface. The function takes a handle of opened video transmitter device (returned by GenTL_OpenDevice) and returns a new handle to its software stream module settings. You can use GenApi functions to access module settings.

For every call to GenTL_OpenDeviceStreamModuleSettings a GenTL_CloseHandle function must be called on returned handle. Device will be closed after all device and device module settings' handles have been closed.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Device has no stream module or failed to open stream module.
- GenICam device description xml file of software module could not be loaded.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_OpenInterfaceModuleSettings

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens configuration node set (an interface module configuration) of GenTL provider communication interface.

Syntax

```
GenTLHandle avl::GenTL_OpenInterfaceModuleSettings
(
 const atl::String& inLibraryPath,
 const atl::String& inInterfaceId
)
```

Parameters

	Name	Type	Default	Description
➡	inLibraryPath	const String&		Path identifying provider library.
➡	inInterfaceId	const String&		String identifying communication interface which should be accessed.

Description

This function allows to access communication interface extended settings through GenAPI system. The function will open specified provider library interface module and return a handle to its instance. You can use GenApi functions to access module settings. These settings affect software-side transport layer of requested interface.

For every call to GenTL_OpenInterfaceModuleSettings a GenTL_CloseHandle function must be called on returned handle.

Exceptions

This function will throw an exception in the following situations:

- Invalid provider library path or interface id is specified.
- GenICam device description xml file of software module could not be loaded.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_OpenLibrarySystemModuleSettings

Header: Genicam.h
Namespace: avl
Module: Genicam

Opens configuration node set (a system module configuration) of GenTL provider library.

Syntax

```
GenTLHandle avl::GenTL_OpenLibrarySystemModuleSettings
(
 const atl::String& inLibraryPath
)
```

Parameters

	Name	Type	Default	Description
→	inLibraryPath	const String&		Path identifying library which system module should be accessed.

Description

This function allows to access library extended settings through GenAPI interface. The function will open specified library system module and return a handle to its instance. You can use GenApi functions to access module settings. These settings affect software-side transport layer across whole provider library.

For every call to GenTL_OpenLibrarySystemModuleSettings a GenTL_CloseHandle function must be called on returned handle.

Exceptions

This function will throw an exception in the following situations:

- Invalid provider library path is specified.
- GenICam device description xml file of software module could not be loaded.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_ReceiveImage

Header: Genicam.h
Namespace: avl
Module: Genicam

Receives next frame from video stream.

Syntax

```
void avl::GenTL_ReceiveImage
(
 GenTLHandle inDeviceHandle,
 avl::Image& outImage,
 atl::Optional<atl::uint64&> outFrameId = atl::NIL,
 atl::Optional<atl::uint64&> outTimestamp = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GenTLHandle		Handle of an opened device that is streaming video.
←	outImage	Image&		Image buffer that will receive a new frame.
←	outFrameId	Optional<uint64&>	NIL	Frame block Id set by device (when supported)
←	outTimestamp	Optional<uint64&>	NIL	Frame capture timestamp set by device (when supported)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outFrameId**, **outTimestamp**.

Read more about Optional Outputs.

Description

This function will return the next available frame from incoming buffer. When input buffer is empty the function will block execution and wait for the next frame to be completed.

The function returns only complete and valid frames, when a frame is corrupted and it cannot be fixed, it is automatically discarded by the library.

A frame is converted from the device stream pixel format to the best suitable format of avl::Image. Automatic conversion includes:

- Conversion from Bayer color mosaic to RGB.
- Conversion of YUV to RGB.
- Ordering of RGB/aRGB channels.
- Unpacking 10, 12 or 14 bpp into 16 bpp images.

Returned image can contain 1, 3 or 4 channels with sint8, uint8 or uint16 pixel type.

outFrameId parameter is optional (can be set to Nil, when not used or given a reference to an output variable). This parameter returns a sequentially incremented number identifying current frame in video sequence. Support of this parameter is optional and for some devices this parameter can be not effective. The value of this output is supplied by the GenTL provider library. Its support, range and wrap around depends on GenTL provider library and transport technology of the device. Refer to device vendor documentation for more information about Buffer FrameId. This value can be used to control correctness of received image sequence and detection of lost frames. Please note that this method can be used only to detect frames that was lost on application side. Detection of frames lost in device and transport layer depends on GenTL provider library implementation and device transport technology.

outTimestamp parameter is optional (can be set to Nil, when not used or given a reference to an output variable). This parameter returns a timestamp of current frame. Support of this parameter is optional and for some devices this output can be not effective. Frequency of the timer used for this timestamp is device and GenTL provider library dependent. Refer to device documentation for details about timestamp timer. Value of this output will wrap around in range from 0 to $2^{31}-1$.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Device video stream is not initialized.
- Timeout occurred when waiting for next complete frame.
- Device sends image in pixel format that cannot be converted.
- Device streams in a mode that does not transport images or the library is unable to read the image from stream.

Remarks

> **Warning:** All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GenTL_OpenDevice – Opens a handle to a device provided by GenTL library.
- GenTL_StartAcquisition – Initializes and starts image acquisition in a device.

GenTL_StartAcquisition

Header: Genicam.h
Namespace: avl
Module: Genicam

Initializes and starts image acquisition in a device.

Syntax

```
void avl::GenTL_StartAcquisition
(
 GenTLHandle inDeviceHandle,
 const atl::String& inPixelFormat,
 int inInputQueueSize = 1
)
```

Parameters

	Name	Type	Range	Default	Description
➡	inDeviceHandle	GenTLHandle			Handle of an opened device that should start acquisition.
➡	inPixelFormat	const String&			Pixel format name in GenICam naming convention that will be configured as device stream PixelFormat parameter.
➡	inInputQueueSize	int	1 – 200	1	Number of incoming frames that can be buffered before the application is able to process them.

Description

This function opens device stream, sets up the device to stream with specified pixel format, prepares internal buffers for stream and starts acquisition in device by executing StartAcquisition command.

Set **inPixelFormat** parameter to empty string to leave current device pixel format unchanged.

Use GenTL_GetPixelFormats function to determine device supported pixel formats and their names.

Do not access GenICam StartAcquisition and StopAcquisition commands directly, always use GenTL_StartAcquisition and GenTL_StopAcquisition functions so that the library state can stay in sync with device state.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Device is not a video transmitter.
- Specified pixel format name is not supported by device.
- Device connection is lost.
- Other general GenTL or GenICam error occurred.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

See Also

- GenTL_StopAcquisition – Stops image acquisition in a device.

GenTL_StopAcquisition

Header: Genicam.h
Namespace: avl
Module: Genicam

Stops image acquisition in a device.

Syntax

```
void avl::GenTL_StopAcquisition
(
 GenTLHandle inDeviceHandle
)
```

Parameters

	Name	Type	Default	Description
➡	inDeviceHandle	GenTLHandle		Handle of an opened device that should stop acquisition

Description

This function stops acquisition started by GenTL_StartAcquisition. The function will not fail when a device is not streaming video.

Do not access GenICam StartAcquisition and StopAcquisition commands directly, always use GenTL_StartAcquisition and GenTL_StopAcquisition function so that the library state can stay in sync with device state.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.

GenTL_TryReceiveImage

Header: Genicam.h
Namespace: avl
Module: Genicam

Receives next frame from video stream.

Syntax

```
bool avl::GenTL_TryReceiveImage
(
 GenTLHandle inDeviceHandle,
 int inTimeout,
 avl::Image& outImage,
 atl::Optional<atl::uint64&> outFrameId = atl::NIL,
 atl::Optional<atl::uint64&> outTimestamp = atl::NIL
)
```

Parameters

	Name	Type	Default	Description
→	inDeviceHandle	GenTLHandle		Handle of an opened device that is streaming video.
→	inTimeout	int		Maximum time, in milliseconds, that the function is allowed to wait for the next complete frame. This parameter overrides global frame timeout configuration.
←	outImage	Image&		Image buffer that will receive a new frame.
←	outFrameId	Optional<uint64&>	NIL	Frame block Id set by device (when supported)
←	outTimestamp	Optional<uint64&>	NIL	Frame capture timestamp set by device (when supported)

Optional Outputs

The computation of following outputs can be switched off by passing value atl::NIL to these parameters: **outFrameId**, **outTimestamp**.

Read more about Optional Outputs.

Description

This function is a close equivalent of GenTL_ReceiveImage, that gives additional control over frame timeout situation.

See GenTL_ReceiveImage definition for more information.

Return Value

true when new frame is successfully received and stored into **outImage**, false when timeout occurs or device is not streaming.

Exceptions

This function will throw an exception in the following situations:

- Device handle is invalid.
- Connection with device is lost.
- Device sends image in pixel format that cannot be converted.
- Device streams in a mode that does not transport images or the library is unable to read the image from stream.

Remarks

Warning: All tools applied to a specific device or file should be managed within a single thread to ensure centralized tracking, traceability, and consistency throughout the process.
